Acerca de este libro

Esta es una copia digital de un libro que, durante generaciones, se ha conservado en las estanterías de una biblioteca, hasta que Google ha decidido escanearlo como parte de un proyecto que pretende que sea posible descubrir en línea libros de todo el mundo.

Ha sobrevivido tantos años como para que los derechos de autor hayan expirado y el libro pase a ser de dominio público. El que un libro sea de dominio público significa que nunca ha estado protegido por derechos de autor, o bien que el período legal de estos derechos ya ha expirado. Es posible que una misma obra sea de dominio público en unos países y, sin embargo, no lo sea en otros. Los libros de dominio público son nuestras puertas hacia el pasado, suponen un patrimonio histórico, cultural y de conocimientos que, a menudo, resulta difícil de descubrir.

Todas las anotaciones, marcas y otras señales en los márgenes que estén presentes en el volumen original aparecerán también en este archivo como testimonio del largo viaje que el libro ha recorrido desde el editor hasta la biblioteca y, finalmente, hasta usted.

Normas de uso

Google se enorgullece de poder colaborar con distintas bibliotecas para digitalizar los materiales de dominio público a fin de hacerlos accesibles a todo el mundo. Los libros de dominio público son patrimonio de todos, nosotros somos sus humildes guardianes. No obstante, se trata de un trabajo caro. Por este motivo, y para poder ofrecer este recurso, hemos tomado medidas para evitar que se produzca un abuso por parte de terceros con fines comerciales, y hemos incluido restricciones técnicas sobre las solicitudes automatizadas.

Asimismo, le pedimos que:

+ *Haga un uso exclusivamente no comercial de estos archivos* Hemos diseñado la Búsqueda de libros de Google para el uso de particulares; como tal, le pedimos que utilice estos archivos con fines personales, y no comerciales.

+ *No envíe solicitudes automatizadas* Por favor, no envíe solicitudes automatizadas de ningún tipo al sistema de Google. Si está llevando a cabo una investigación sobre traducción automática, reconocimiento óptico de caracteres u otros campos para los que resulte útil disfrutar de acceso a una gran cantidad de texto, por favor, envíenos un mensaje. Fomentamos el uso de materiales de dominio público con estos propósitos y seguro que podremos ayudarle.

+ *Conserve la atribución* La filigrana de Google que verá en todos los archivos es fundamental para informar a los usuarios sobre este proyecto y ayudarles a encontrar materiales adicionales en la Búsqueda de libros de Google. Por favor, no la elimine.

+ *Manténgase siempre dentro de la legalidad* Sea cual sea el uso que haga de estos materiales, recuerde que es responsable de asegurarse de que todo lo que hace es legal. No dé por sentado que, por el hecho de que una obra se considere de dominio público para los usuarios de los Estados Unidos, lo será también para los usuarios de otros países. La legislación sobre derechos de autor varía de un país a otro, y no podemos facilitar información sobre si está permitido un uso específico de algún libro. Por favor, no suponga que la aparición de un libro en nuestro programa significa que se puede utilizar de igual manera en todo el mundo. La responsabilidad ante la infracción de los derechos de autor puede ser muy grave.

Acerca de la Búsqueda de libros de Google

El objetivo de Google consiste en organizar información procedente de todo el mundo y hacerla accesible y útil de forma universal. El programa de Búsqueda de libros de Google ayuda a los lectores a descubrir los libros de todo el mundo a la vez que ayuda a autores y editores a llegar a nuevas audiencias. Podrá realizar búsquedas en el texto completo de este libro en la web, en la página `http://books.google.com`

This is a reproduction of a library book that was digitized by Google as part of an ongoing effort to preserve the information in books and make it universally accessible.

SUMMARY

The Incorporated Municipal Electrical Association met at Nottingham on Tuesday to hold its thirteenth Annual Convention, under the presidency of Mr. Herbert Talbot, Chief Electrical Engineer to the Nottingham Corporation. In his Presidential Address Mr. Talbot put in a plea for the better encouragement of assistant engineer members of the Association, suggesting that many could be spared from the station at this time of the year, and that their expenses should be paid by their Committees. Other points touched on by Mr. Talbot were the use of metal filament lamps, the maximum demand system of charging, the registration of wiring contractors, destructor stations, reserve funds, purchasing meters out of revenue, uniformity of plant, and the desirability of "continuity" of Chairmen and members of Committees. A Paper by Bailie Wightman, Convener of the Govan Electricity Committee, was next discussed, and the speakers were unanimous that the Chairmen of the Electricity Committees should not intervene in technical matters at all, but should leave these entirely to their engineers. Alderman Pearson, Chairman of the Bristol Electricity Committee, stated that on the occasion of the fire at their electricity works he had not even telephoned to Mr. Proctor, the engineer-in-chief, but had gone to bed with the assurance that he would see matters through. There was also an agreement as to desirability of continuity in Chairmen and Committees. Most of the speakers had been successful in this, but one Councillor complained that his Committee had had the experience of five Chairmen in two months. (Page 5.)

As considerable attention has been directed of late to the fact that under the new Patents Act British patents may be revoked if the patented article or process is manufactured or carried on solely or mainly abroad, we publish once more the full text of the clause in question. It only applies to patents four years after they have been filed, and comes into force on August 28th next. The clause will eventually lead to an increase in the number of metal filament lamps manufactured in this country, and we may look for a considerable development in this direction even before the end of this year. (Page 10.)

The equipment of the Aldgate and Bow section of the L.C.C. tramways which has recently started running under electric traction, is on the Griffiths-Bedell system already in successful use on a short line at Lincoln. The principal feature of the system is the provision under the studs in the road of a bare feeder cable partly of magnetic material supported on insulators in an earthenware pipe. The body of each stud contains a plunger normally held up by a spring, which, however, becomes magnetic and attracts itself down to the cable and makes contact with it when the powerful

Digitized by Google

magnet on the car passes over it. The heads of the studs are of cast-iron, and are sunk into granite blocks, so that they do not project appreciably above the surface of the roadway. The action of the flexible chain which forms the actual collector on the car is somewhat similar to that of the plunger within the stud. Lying normally clear of the road surface in a groove in the surface of the wide pole face of the car magnet, it is attracted down to the iron stud-head and makes contact as it passes over. The plungers in the studs are provided with carbon contacts, although they are not usually required to break the circuit, as the studs are so spaced that the collector does not leave one stud before it has made contact with the next in front. Provision is to be made for through running on the conduit lines, and for this purpose the cars are to be equipped with the ordinary plough as well as the collecting chain. The cars at present running are, however, fitted only with the surface-contact apparatus. (Page 11.)

AMONG the electrical exhibits at the German Shipbuilding Exhibition now being held in Berlin is an interesting electrically operated system for the coaling of ships at sea. Turbo-generator sets of particularly light and compact construction and motor generators for supplying constant current for searchlights are also shown. (Page 16.)

A PAPER was read by Mr. J. HÄRDEN at the last meeting of the Faraday Society upon the Electric Induction Furnace, in which improved forms of the Kjellin Röchling-Rodenhauser electric induction furnaces were described. Quite a number of induction furnaces are already in use in this country, including a 150-kw. Kjellin furnace used by Messrs. VICKERS, SONS & MAXIM, and a 60-kw. experimental furnace at Battersea. (Page 17.)

THE results of some severe tests on a pair of slow speed 1,500-kw. continuous-current generators supplied by SIEMENS BROTHERS' DYNAMO WORKS to the War Department are of interest, as these are amongst the largest machines with commutating poles which have been constructed. Some tests on a 100-h.p. motor with a range in speed of one to six are also given. (Page 20.)

SOME new switchboard apparatus and meters, including a three-phase potential transformer, a portable ampere hour meter and a double reverse current relay for continuous current, are described in a short illustrated article. (Page 21.)

THE collective exhibit which was organised by the Electric Supply Companies of London in the Machinery Hall at the Franco-British Exhibition is now complete. The display consists of a central reception room and information bureau, opposite which is a complete furnished model flat fitted up to demonstrate the domestic applications of electricity. Surrounding these are a number of stands occupied by leading electrical firms. A wide range of electrical activity is represented, and not the least interesting amongst the exhibits are the examples of no less than four new British-made metal filament lamps shown by the SUNBEAM LAMP CO., the EDISON & SWAN CO., the BRITISH THOMSON-HOUSTON CO., and the STEARN ELECTRIC LAMP CO. respectively, some of which are exhibited for the first time. Examples of the new high tension switchgear of Messrs. REYROLLE & CO. are on view, and an interesting feature of the furnished flat is the complete electrical kitchen equipped by Messrs. RASHLEIGH, PHIPPS & CO. (Page 23.)

Mr. F. J. ALLAN, Medical Officer of Health to the City of Westminster, has found the tubercle bacillus in the mouth-piece of a telephone at a public call-office. He had six mouth-pieces in these situations tested by Dr. KLEIN, and only one was so infected. Three years ago Dr. COLLINGRIDGE, Medical Officer of Health to the City of London, made a similar investigation in the case of twelve mouth-pieces, but none were found to be infected either with the tuberculosis or diphtheria bacillus. It is desirable that a better system of ventilation should be adopted in public telephone boxes. (Page 29.)

UNDER "Electrochemistry and Electrometallurgy" is a note on the suggested use of iron resistances for regulating current when charging batteries. At the last meeting of the Faraday Society Mr. A. JOUVE read a Paper upon the new applications of Electrometallurgical Alloys, dealing mainly with the use of silicon alloys, particularly with ferro-silicon. (Page 29.)

UNDER "Electrical Science," in the British and American Section, is an abstract of a Paper on secondary radiation from metals. At the second conversazione of the Royal Society, two new exhibits of electrical interest were shown. In the Continental Section an apparatus devised by JÉGON for testing the sensitiveness of detectors is described. In a Paper by DEMBER, the author claims that he has liberated canal rays from zinc by means of ultra-violet light. An analysis of microphone oscillations by means of the oscillograph is described by DEVAUX-CHARBONNEL. (Page 29.)

THE Radio-Telegraphic Convention came into force on Wednesday. We give an outline of the provisions of the Convention and a list of countries adhering. (Page 10.)

THE accounts of the Bradford Tramway Department show considerable increase in revenue over last year. The receipts per car mile amounted to 10.591d., which is slightly less than last year, but the gross profit has increased from £72,524 to £75,154. The tramway lines from Dalmuir to Balloch, which form the last link of the through route from Glasgow to Loch Lomond, were opened for traffic last Thursday.—The Exeter Electric Lighting Accounts show a net balance of £2,604, which is the largest obtained in any year since the Council acquired the undertaking.—The past year's working of the Fulham Electricity Department has resulted in a surplus of £4,408, of which £1,000 is to be transferred to machinery, maintenance and reserve accounts.—The net surplus shown by the Manchester Electricity Department accounts for the past year is £19,543, of which £10,000 has been paid in aid of rates. (Pages 31-33.)

A LOCAL GOVERNMENT BOARD enquiry has been held into an application by the Manchester Corporation for the loan of £130,500 for extensions to generating plant representing some 12,000-kw. We are able to give particulars of a large number of projected new buildings in London and the provinces which will be of interest to wiring contractors. (Pages 34-35.)

THE tenders of Messrs. SIEMENS BROS. for laying telegraph cables between Victoria and Tasmania has been accepted at the price of £47,955. The tender of Messrs. DICK, KERR & CO. for the construction of tramways between Frien Barnet and New Southgate has been accepted. An order has been given to the OERLIKON CO. for two 6,000 turbo generators for Stockholm. It is announced that the Metropolitan District Railway is about to discontinue the use of pneumatic doors to their carriages and to substitute hand operation. (Pages 35-37.)

THERE was a very good attendance at the Special General Meeting of the Institution of Electrical Engineers on Tuesday last, when the question of the proposed acquisition of the building known as the Medical Examination Hall was under consideration. The financial side of the question was dealt with by Mr. R. HAMMOND, and Mr. W.

Digitized by Google

M. MORDEY discussed the subject from the general point of view. Certain members present objected to the hurry in which the matter was being rushed through, and others expressed themselves dissatisfied with the building. An amendment was proposed referring the matter back to the Council, but this amendment was lost by a large majority. The resolution sanctioning the purchase of the building was finally carried unanimously. (Page 38.)

ON Friday Lord CROMER'S Committee passed the preamble of the London (Westminster and Kensington) Electric Supply Companies Bill. This Bill gives the five West End Electric Lighting Companies power to link up for the purpose of mutual supply and also power to supply electrical energy in their respective areas for use outside. A further clause related to the certification of meters. On Monday the Committee commenced consideration of the clauses of the London and District Electric Power Bill. (Page 39.)

A NEW type of automatic switch for use with small auto-transformers supplying metal filament lamps has been devised. The switch is particularly simple in construction and is combined with the transformer in a single case. By a simple arrangement of the connections, the meter shunt losses during periods of inactivity, as well as the transformer no-load losses, are obviated. (Page 40.)

IN accordance with the Census of Production Act of 1906, which comes into force this year, forms are being sent out to electrical engineers requesting statistical information with regard to their business. (Page 41.)

A NEW type of wall connection which can be fixed to the wall without screws, and a new porcelain lamp-holder specially suitable for use in the presence of acid fumes, are described. (Page 41.)

AT the meeting of the British Electric Traction Co., on Thursday, Sir C. RIVERS WILSON, who presided, stated that an unwarranted impression seemed to prevail that the general position of the company was not satisfactory. He wished to emphasise, however, that this was entirely erroneous, for whereas the total amount on the debit side of the balance sheet was £5,009,165, there were assets amounting to £5,658,653. He claimed that very few companies in England could show an equally strong financial position. At the end of his speech he made some remarks with regard to the effect upon the electrical industry of municipal trading. (Page 43.)

A METHOD of changing from series to parallel connection in the control of series-wound traction motors is the subject of a Patent Specification by the BRITISH THOMSON-HOUSTON Co. The change over is effected without breaking the motor circuit. Among the other specifications published on Thursday last was one by G. MARCONI, describing a form of wireless telegraph transmitter for emitting oscillations in regular groups so as to produce a recognisable note in the telephone at the receiving station. An improved arrangement of aluminium electrolytic rectifiers is described in a specification by SIEMENS BROTHERS & Co., and another by the AMALGAMATED RADIO-TELEGRAPH Co. refers to the resistance of microphones used in wireless telegraphy. A specification by the ALLGEMEINE ELEKTRICITÄTS-GESELLSCHAFT relates to flexible supports for metal filaments. A process for the hardening of tantalum is the subject of a specification by the SIEMENS & HALSKE AKT.-GES., and SIEMENS BROTHERS & Co. have another describing a method of protecting the wires of thermo-electric pyrometers from the action of the vapours and gases given off from molten metal and other baths. (Page 44.)

THE adoption of a surface contact system by the London County Council for a short section of their tramways in the Mile End Road, has been looked askance upon by several groups of persons. These include not only conservative tramway engineers, who will never admit that any good can possibly come of a surface contact system, but also those whose words are prompted by political rather than engineering considerations, and search to find fault with the system because it was adopted by a party not of their way of thinking in other matters. The former point to the small degree of success attending certain other surface contact tramways, from reasons not present in this case, and the latter keep careful record of the few trivial cases of live studs which occurred before the cars were running and before the adjustments were complete. The G.B. system has met with a considerable measure of success at Lincoln, and as the detailed description of the L.C.C. line in our columns this week will show, the equipment possesses one or two most interesting features. The magnetic action by which the collection chain is made to approach the stud at the right moment, and which causes the stud to so to speak lay its finger on the live cable underneath, is ingenious as it is simple. The working parts are few and robust, and there is little to go wrong. A good deal of misunderstanding has apparently arisen as to the cause of the long interval which elapsed between the completion of the track equipment and the running of the cars. This was, however, due entirely to what may be described as geometrical difficulties in the combination in a limited space of the surface contact collecting gear with the plough required for through running on the conduit lines, and must be no more attributed to faults of the surface contact system than to complications of the conduit equipment. We trust that the G.B. system will now receive the fair trial by which its reputation must stand or fall, as a system withstanding the ordeal of the exacting conditions of London traffic can with safety be adopted for almost any class of tramway work.

MR. HERBERT TALBOT, in his Presidential Address to the Incorporated Municipal Electrical Association on Tuesday, dealt with a number of matters which are occupying the attention of borough electrical engineers and their committees, and some that are being discussed in a wider field. An important question which may be included in the category of home politics, and is frequently recurring, is the relation of the assistant electrical engineers to the Association. We must confess that we can quite sympathise with the attitude of the chief assistant who asks what object he can have in joining the Association, since he is not able to go to the meetings when his chief is also absent from home, and as he can also read the Papers and reports of the discussions in his weekly technical journal. In the majority of cases it is obviously not desirable that both the chief engineer and his chief assistant should be away from their towns simultaneously, and in no cases would it be possible for several assistants to be away on leave at the same time; so that it is only when the meetings are at a large centre, such as London or Manchester, near

Digitized by Google

which there are a large number of municipal electricity works within a half-hour's or an hour's journey, that any considerable attendance of assistant engineers would be possible. The travelling scholarship scheme suggested by Mr. McARTHUR BUTLER, Secretary of the Association, and taken up with cordial approval by the Council, certainly appeared to be an excellent one, but its results have been disappointing. It only produced one Paper last year, and none at all this year, and has not had the effect of increasing the number of assistant engineers who have joined as Associate Members or Associates. There can be no doubt that it would be an advantage, both to the Association and to the men themselves, if they joined, in greater numbers, the body which identifies itself with the interests of municipal electrical work, and we would urge that consideration be given once more to a proposal which, we believe, was put forward at one time but was withdrawn owing to the lack of enthusiasm of the few assistant engineers who are at present connected with the Association. It is not only these few who are to be thought of, however, but the far larger number who have not found it worth their while to become members of an Association which can offer them only a limited inducement to join. Our proposal is that there be periodical conventions of Associates and Associate Members, for the discussion of Papers and for the same general objects as the present meetings of Members. The section comprising Associate Members and Associates should have their own Committee and a Chairman, who would have access to the actual Council of the Association, and various other details of organisation would have to be elaborated to make the scheme complete. It may be objected that such meetings of Associates and Associate Members only would tend to create a kind of trade union tone among this class, and that grievances would be aired, and combined action threatened against their employers, but we do not believe that there would be any risk of this. The assistant engineer is too well acquainted with trades union methods to wish to imitate them. If meetings were held three or four times a year, every Associate would have an opportunity of attending at least once in the year, for we are confident that there would be no difficulty in obtaining leave for this. A large amount of valuable information would be exchanged, and not only would the whole standing of the assistant engineer be improved, but his knowledge and views of technical and administrative matters would be greatly broadened. Although there are very able men among the ranks of the assistant electricity works engineer, there is certainly room for much improvement generally in this respect. We put this proposal forward as a means of extending advantageously the sphere of utility of the Association, and we trust that it will be taken up once more by those in authority.

IN the discussion on Bailie WIGHTMAN'S Paper, on Tuesday, some speakers made a grievance of the fact that only one Paper invited discussion on subjects of particular interest to Chairmen and Members of Electricity Committees, and urged the Council of the Association to make arrangements for two Papers of this nature at future meetings. Those who spoke, however, do not realise the extreme difficulty that the Council have even in obtaining a single Paper from among the Chairmen of the Electricity Committees. There is a general invitation to any of them to submit Papers, and a number are written to individually and asked to contribute one for discussion, but each year practically all are too modest to express their views in this form. An amusing but eminently practical suggestion was made to us at Tuesday's meeting. One of the engineers should be asked to contribute a Paper on "How to Manage a Chairman," and his Chairman should read a Paper on the same day on "How to Choose an Electrical Engineer." The discussion on such a pair of Papers would be interesting, although it might be necessary that the authors' replies should be curtailed, and that the two writers should be billeted at different hotels.

ARRANGEMENTS FOR THE WEEK

TO-DAY, THURSDAY, JULY 2ND.

Incorporated Municipal Electrical Association.

10 a.m. Third Day of Convention at Nottingham. Annual General Meeting at the University College.

2.30 p.m. Meeting at the University College, when the following Papers will be read and discussed:—(1) "Some Considerations on the Design of a Generating Station," by H. Richardson (Dundee); (2) "The Reconstructions of an Electric Lighting Scheme with Observations on the Working of a Combined Steam and Water Power Plant," by C. M. Shaw (Worcester).

7.30 for 7.45 p.m. Association Dinner at the Exchange Hall.

Royal Society of Arts.

9 p.m. to 12 p.m. Conversazione at the Natural History Museum, South Kensington, S.W.

FRIDAY, JULY 3RD.

Incorporated Municipal Electrical Association.

10 a.m. Fourth Day of Convention at Nottingham. Meeting at the University College, when the following Papers will be read and discussed:—(1) "A.C. Accumulator Sub-station, and the Use of Accumulators for Peak Loads," by A. M. Taylor (Birmingham); (2) "The Work and Equipment of a Testing and Standardising Department," by H. A. Ratcliff (Manchester).

THURSDAY, JULY 9TH.

Tramways and Light Railways Association.

11 a.m. First Day of Annual Congress. Meeting in the Congress Hall of the Franco-British Exhibition, when Sir Clifton Robinson (vice-president) will give a lecture on "The Tramways of the World," followed by a Paper on "Tramway Rail Joints," by Mr. A. H. Gibbings.

FRIDAY, JULY 10TH.

Tramways and Light Railways Association.

11 a.m. Second Day of Congress. Meeting in the Congress Hall of the Franco-British Exhibition, when Prof. C. A. Carus-Wilson will deliver a lecture on "Rail Corrugation."

7.30 p.m. Association Dinner at the Banqueting Hall of the Franco-British Exhibition.

Students' Summer Visit to Newcastle.—The Students' party of the Institution of Electrical Engineers leaves St. Pancras at 10 o'clock on Monday morning, July 6th, going first to Derby, where the works of the Midland Railway Company will be visited. Newcastle will be reached that evening, and on Tuesday afternoon the party will visit the works of Messrs. Ernest Scott & Mountain. The works of Messrs. Armstrong, Whitworth & Co., and those of Messrs. J. H. Holmes will be viewed on Wednesday. On Thursday the party goes over the works of Messrs. Clark, Chapman, Ltd., and the Consett Iron Works. The shipyards of Messrs. Swan, Hunter & Wigham Richardson, and the works of the Harden Collieries will occupy the greater part of Friday, and the Carville power station will be visited on Saturday, the party returning in the afternoon to London. Mr. Moss, Chairman of the Students' Section, will take charge of the party after leaving London.

THE THIRTEENTH CONVENTION OF THE INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION

THE 1908 Convention of the Incorporated Municipal Electrical Association was opened at Nottingham on Tuesday and will be continued to-morrow. The Association met at 10.30 a.m. at the University College, the attendance being about 200. The Mayor of Nottingham (Mr. Councillor Spalding) and the Sheriff (Mr. Councillor Carey) were present and welcomed the Association.

The MAYOR said that this was an exceptional year for Nottingham, for no less than nine or ten conferences were to be held there, but the Corporation would be pleased to welcome them all. He was pleased on this occasion to welcome the Incorporated Municipal Electrical Association, for as far as municipal electricity was concerned, Nottingham was exceptionally fortunate. It was due in a great measure to Mr. Talbot, the President of the Association, that the undertaking had been such a great success. Last year the Electricity Committee contributed no less than £11,500 towards the relief of rates, which must be unique throughout the whole country. Although there might be a little cause for complaint with respect to the price that was charged in Nottingham for lighting, still he thought, on the whole, the inhabitants were to be congratulated on the great success which had attended the undertaking. He trusted that the result of the conference would be beneficial, not only to the Association, but also to the various towns represented by its members. In the name of the citizens of Nottingham he bade the Association a very hearty welcome.

Mr. COUNCILLOR CAREY, Sheriff of Nottingham, said he felt it a great honour to be able to join in the welcome to the Association. It had been said that Edinburgh was the first city in the world, and that Nottingham was second. Although he held that Nottingham was one of the finest cities, it was a great question to him as to whether it could really be classed as second in the world. Nevertheless, he could assure them that they would see much to gratify them and much to please them, not only in the scenery round Nottingham, but also in the various enterprises which the city of Nottingham carried on so successfully.

Mr. H. TALBOT, the Chief Electrical Engineer to the Nottingham Corporation, having proposed a vote of thanks to the Mayor and Corporation for their welcome, which was acknowledged by the Mayor, then delivered his Presidential Address, which is given below.

PRESIDENTIAL ADDRESS.

BY HERBERT TALBOT.

(*Chief Electrical Engineer, Nottingham.*)

Mr. MAYOR, LADIES AND GENTLEMEN—

We are assembled this morning as representatives of Municipal Electricity Supply, either as members of electricity committees or electrical engineers, to commence our Thirteenth Annual Convention. The common ground on which we meet is that of giving an efficient and cheap supply of electricity to all consumers and for all purposes, consistent with the principle that the long hour consumer shall not be called upon to pay part of the cost incurred in supplying the short hour, or in other words, the non-profitable consumer, and I assume that one of the main ideas at these Conventions is to strengthen and encourage one another in our efforts for this attainment.

Before continuing, I beg to thank the members of the Association most sincerely for the great honour they conferred upon me when they elected me President. It is the highest honour which you are able to bestow, and one which any member might be proud to accept. I fully appreciated the great responsibilities of the position, and accepted it with great diffidence, knowing well what able engineers had held the office previously.

I wish to congratulate the members on the continued success of the Association. When it was formed thirteen years ago there were many, I think, who were of opinion that it would be of little use, and would become defunct in the course of a few years. I am pleased to see how much the work of the Association is appreciated by all classes of its members. This, I think, is proved by the continued membership and by the number of members who attend the Annual Conventions. There can be no question to my mind of the utility of an Association like ours, and of the benefits derived by both chairmen of committees and engineers attending our Conventions, for they all have every opportunity of meeting gentlemen interested in exactly similar undertakings, and they are enabled to compare notes and obtain most useful and valuable information, which could hardly be obtained in so pleasant a manner elsewhere.

One very important work which has been carried out by the Association during the last few weeks, which will be mentioned in the Annual Report, has been in connection with the "Home Office Regulations," and I should like to place on record my very high appreciation of the way in which your Honorary Solicitor, Alderman Pearson, your Honorary Secretary, Mr. H. Faraday Proctor, and your Vice-President, Mr. W. W. Lackie, worked in connection with the Conference that was held in Westminster by the Commissioner appointed by the Home Office to hear the views and suggested amendments proposed by a large body of objectors.

ASSISTANT ENGINEERS.

Two years ago your President, Mr. Edgcome, in his address, mentioned the fact that out of a possible 800 assistant engineers eligible for election as Associates, only sixty-one had joined the Association. Although your Council, with the view of encouraging assistant engineers to take an interest in the Association by writing papers, offered travelling studentships for competition, only one such studentship was gained last year by Mr. McCourt, of Harrogate, for his very complete and interesting Paper on "The Value of Photometry in Central Station Work." This year no Paper has been received from any Associate, and the number of Associates has slightly decreased. Now there must be some cogent reason why such apparent apathy is shown by assistant engineers, and I do not think we have far to seek for a solution of the difficulty. With my own assistants, I have asked them on several occasions why they do not join the Association, and the answer invariably is: "Why should we? We *cannot* attend the Convention, and we can read the Papers and Discussions when the proceedings are published." Everyone will admit that many of the assistant engineers of to-day will eventually become chief engineers somewhere or other in the course of time, and I would strongly advise the chairmen of committees and chief engineers to see if something cannot be arranged so that assistant engineers can be induced to join the Association, and thereby become interested in the valuable Papers that are read at our Conventions and in the more valuable discussions which take place. As the Conventions always take place in the summer, when stations are working at their minimum output, it ought to be quite feasible to allow one or more assistants to attend the Convention, and should a difficulty be found in the matter of expense to the assistant, I do not see why his expenses should not be paid by his committee, for most certainly the assistant would become more useful in his work, and the advantage would be with his committee, and at a very trifling cost.

METALLIC FILAMENT LAMPS AND SYSTEMS OF CHARGING.

In his address last year your President, Mr. Fedden, said it was more difficult year by year to prepare matter which contains anything novel and instructive, and as he touched upon almost every subject, I find it much more difficult to do so this year, and as I do not wish to detain you or tire you, I will abbreviate my address as much as possible, as I am certain you will be more interested in the discussion of the various Papers than you would be in any address I could prepare. Having briefly touched upon a few points in connection with our Association, we may, perhaps, turn our attention with advantage to some of the more important considerations which affect our undertakings and the supply of electricity for lighting purposes.

The past year has been comparatively uneventful, with the exception of one feature. I refer to the continually increasing use of metallic filament lamps. It is certainly interesting to note that after over 30 years' careful work in improving the carbon filament lamp, a return should be made to the use of metals and their alloys for the substance of the filament, and it would be interesting to know whether the advent of these lamps will not result in the carbon filament lamps becoming obsolete. What ultimate effect these new lamps will have upon our undertakings it is, of course, impossible to predict, but there can be no doubt that any improvement in

Digitized by Google

the present extravagant methods of producing light must eventually prove beneficial to every one.

Of course, the use of these new lamps necessarily involves a considerable reduction in the revenue of an undertaking, but at the same time it is to the immediate advantage of the consumer who keeps his installation up-to-date. One of our up-to-date consumers told me the other day that, by using metallic filament lamps, he would soon bring the cost of lighting his shops down to less than it used to cost him for gas. This reduction of revenue can only be temporary, as the cheapening of the light will have the effect of enormously increasing the number of our consumers, and so necessitate a larger output in the near future, although for the time being it may go hard with contractors for electrical plant, as extensions will not be required so soon.

This brings us to the point as to the best means of increasing the number of our consumers, and I think the fairest way is to offer special inducements to the most profitable ones. This naturally raises the much vexed question of "Flat Rate *v.* Other Methods of Charging." There can be no doubt that the flat-rate method of charging is unjust, and that its only recommendation is its extreme simplicity. The use of a scale of discounts increasing with the number of units consumed only tends to aggravate the injustice. The "maximum demand" system is, after all, the fairest and most equitable method of charging which has been devised up to the present. It falls short of absolute equity, inasmuch as we are unable to differentiate between those who do and those who do not make use of their maximum demand at the time of maximum load on the supply station, but this, I think, is of very slight importance. In Nottingham we use the maximum demand method of charging, and during last year 491 consumers, whose average price was under 3d. per Board of Trade unit, consumed 46 per cent. of the total output of electricity supplied for lighting purposes. The remaining 2,840 lighting consumers took the other 54 per cent. I mention this as my Committee has recently been approached by the Combined Traders' Association, asking them to adopt a flat rate not exceeding 3d. per unit, and when I say that the average price per unit of some of our largest consumers is as low as 1·92d., it seems unreasonable to penalise them for the benefit of the consumers upon whom we lose money.

There seem to be very great difficulties in getting the average consumer to understand this system; difficulties which appear to be in inverse proportion to the number of units obtained at the lower rate. If we could devise some simple method of educating the consumer to understand that a capital expenditure of £4 to £6 must be incurred by the undertakers for every 16 candle-power lamp, or its equivalent supplied, and that approximately 80 per cent. of the plant in the generating station is of necessity standing idle for the greater part of the year, I think he would then admit that, as a consequence, the only rational method of charging is one which allocates to each consumer such share of the standing charges as is incurred on his behalf.

The Registration of Electrical Contractors.

The Corporation of Birmingham has lately issued an announcement stating that it is their intention to register wiring contractors who are authorised to carry out installations in the city. This is a matter which requires much careful consideration. At the outset it must be admitted that a municipality does not appear to be endowed with power to authorise or prevent the carrying out of an electrical installation by any contractor or other person. Nor would it seem that they can refuse to supply such an installation unless the work be done in such a manner as not to comply with one or other of the various Regulations of the Board of Trade. Nevertheless, I cannot but think, and I am sure you will all agree with me, that some scheme whereby workmen should be certified as competent, would prove advantageous alike to the consumer, the supply authorities, and the contractors themselves. Of course, registration would only be a means of minimising, and would not prevent, bad and scamped work, but it would, at least, tend to guard against the deplorable ignorance of some of the electrical workmen of to-day.

It would hardly appear desirable for the municipalities individually to take this work in hand, as a purely local registration would be far too narrow a basis on which to carry out such a scheme. Neither do I think it would be competent for the Association to undertake the work, as it should be of an entirely national character, and would be better carried out by the Electrical Contractors' or similar Association. The registration should be conditional on the gaining of a certificate for the passing of a fairly elementary examination on somewhat similar lines to that instituted by the Worshipful Company of Plumbers.

Town's Refuse as Fuel for Generating Electricity.

At one time it was thought that great results would be obtained by the combination of a generating station with a refuse destructor. There are even now people who refuse to believe that a refuse destructor is not a great financial acquisition to an electricity supply undertaking. Undoubtedly, looked at from the broadest standpoint of the ratepayer, the combination is, perhaps, desirable, as the refuse must be destroyed, and that as effectually and as cheaply as possible. It is a certain fact, notwithstanding, that the handling and burning of the refuse alone costs more than the same output could be obtained for at the coal-fired generating station.

In the case of the Eastcroft Destructor at Nottingham, 28,302 tons of refuse were destroyed during the last year, producing 1,069,885 units. Wages amounting to £2,146, which were paid for stoking this refuse and providing additional engine drivers—otherwise unnecessary, as this output, averaging about 240 kw., could easily have been generated at the main generating station without extra help—brings the cost up to 0·48d. per unit, which would more than pay for the extra steam power required, and to this must be added the increased maintenance and capital charges for plant, &c., at the destructor. Although of such small capacity, the destructor station runs fourteen to eighteen hours per day with a load factor of 28 per cent., and generates 9 per cent. of the total electricity supply for the city.

For the moment this sounds extraordinary and certainly appears to justify the enthusiasm of destructor advocates. They very naturally say: "You have turned out 9 per cent. of your total supply for £2,146, and you say this has cost more than you could have generated it for at your main station. Your total revenue for 11,116,855 units is £90,921. Clearly, therefore, you should pay something for the refuse." A very little consideration, however, will show the higher up the peak of our load curve we get, so does the cost of supplying each unit generated increase out of all proportion, till we come to the last unit at the very top of the maximum load curve, which only occurred one evening in the whole year, which necessitated a capital expenditure of £45, and which brought in the magnificent revenue of 5d. The destructor station of necessity supplies cheap units at the bottom of the curve, and leaves to the main station the task of supplying the expensive ones at the top, with a consequent reduction of the load factor. It must not be thought that I am disparaging the utility of destructors. Towns' refuse must be disposed of, and burning is the most effectual method. This being the case, the cost of burning must inevitably be borne, whether the heat be utilised or not. Under these circumstances it would be a pity not to utilise the heat, even if in so doing the electricity undertaking be asked to contribute indirectly towards the expense of destroying the refuse.

Gas Engines.

As I said at the beginning of my address, our united aim must ever be the giving of a cheap and efficient supply. Unfortunately, in this country we are not blessed to any extent with natural water power, but I think we may look forward with some interest to the possible future introduction of large gas engines, supplied from the waste gases of our blast furnaces. Though the large gas engines at Johannesburg do not appear to have been a success, the report of those engineers who were privileged to view the German installations in October last, was very satisfactory, and I do not think we should neglect to make use of any source of cheap energy.

Batteries.

Much also has been said and written on the subject of batteries for supplying the expensive short hour consumers, who are responsible for the undesirable upper portion of our load curves. I am sure we shall have a most interesting discussion on this subject after the very able paper to be given by Mr. Taylor, who, as you are aware, has devoted much time and attention to this problem.

Reserve Fund.

The vital question of the reserve fund does not appear to receive sufficient attention in many undertakings, although in the early days of a station it may not be possible to set aside a portion of the net profits for this purpose. I do think, though, that as early as possible, this most important fund should be started and added to each year, before anything is given to the relief of the rates. The amount allowed under the Electric Lighting Acts, of one-tenth of the aggregate capital, may, or may not, be sufficient for this purpose, but I am of opinion that it is a wise policy to reach this amount before the plant is

Digitized by Google

worn out, or, more likely, becomes antiquated. I suggest that, further than this, and as soon as convenient, a depreciation fund should also be started. With these two funds in existence an undertaking would be placed on a sound financial basis. In Nottingham our reserve fund stands to-day at £43,926, and this sum is invested outside the Corporation.

PURCHASE OF METERS OUT OF REVENUE.

In several of the recent sanctions for loans under the Electric Lighting Acts, the Local Government Board have advised that meters, and so-called short-lived assets, should be purchased out of revenue. This may also be a sound policy, but it must of necessity reduce the profits of the undertaking by the amount so spent. I think it is found in practice that when a trading concern has once given an amount to the relief of the rates, the Finance Committee, or those responsible for making the rate, expect at least the same amount each year, and this will be impossible so long as plant which certainly should be charged to capital account, has to be paid for out of revenue.

UNIFORMITY OF PLANT.

It is surprising when visiting generating stations how many of them look more like museums than modern stations, and why is it? It cannot be that the plant has cost less, or that it is more efficient, for in some stations you will find the same type of engine coupled to various types of generators, and *vice versa*. To have good sound efficient plant should be the first care of every committee. That this can be obtained with uniformity at the same time is a fact that many of us are agreed upon and appreciate. After having decided upon the type of plant to be installed, why change every time an extension of the plant becomes necessary? There are some who will probably say that it is purely a question of cost, but is it? I am glad to say that my committee has provided as good a plant as it is possible to obtain, and as far as practicable have kept to uniformity, and this at no extra cost. It follows that a contractor will make, say, a dozen machines of one pattern cheaper than he will make the same number of different patterns, and you must therefore gain great advantages in the cost. During the fourteen years our stations have been in operation we have only had to repair four armatures and one field coil, and with the exception of one short stoppage during the daytime, the supply has not been interrupted. I hold no brief for the contractors responsible for our plant, but I must admit how much I appreciate the foresight of the members of my committee.

"CONTINUITY" OF COMMITTEES.

Before concluding I should like to say a few words about the continuity of the chairmen and members of committees, and the advantage of the same. If, instead of frequently changing, the same gentlemen remain in office, it allows them to become conversant with all the details of the undertaking, and they eventually must be of more service to the municipality in watching the interests of all concerned. In this city we have been fortunate in retaining two members on the committee for nearly twenty years, one, Sir John Turney, having been chairman for over sixteen years. He was brought up to the engineering profession, and you can readily understand that with his engineering experience it would have been impossible to select a more suitable man to fill the position.

In conclusion, I have again to thank you for the honour you have conferred upon me, and it will be my duty and pleasure to try and make this Convention as instructive and enjoyable as any of the previous ones.

The morning's proceedings concluded with the discussion of Bailie Wightman's "Experiences":—

THE EXPERIENCES OF A CONVENER.

BY BAILIE WIGHTMAN, J.P.

(Convener of the Govan Electricity Committee.)

INTRODUCTION.

When in the usual course the writer was asked by the Committee to suggest a subject for a Paper he replied by sending in the one which he now proposes to deal with. The Committee very courteously asked him to take it up, to which he consented: but he disclaims any intention of pretending that his experience has been of great importance. His hope, he explained, was to bring out the experiences of others who have held a similar position in other towns.

It is about fifteen years since the Govan Order was acquired. It was not obtained with the immediate intention of putting it into operation, but merely as a precautionary measure, and some years later, when the writer was convener of the Watching and Lighting Committee, the first step was taken to enforce it. A Committee was appointed who contented themselves with marking time, until a new interest was awakened by an application from two separate companies and an inquiry from the Board of Trade as to the Corporation's position in relation to the Order. They declined to entertain the proposals of the London companies, and intimated to the Board of Trade that they were at present considering the matter. Another alternative was to hand over the Order to Glasgow, their near neighbour; but the anti-annexation feeling was too keen for this to be done, and they decided to do the work themselves. They therefore asked an eminent London engineer for a report, and requested him to state his fee in the event of their failing to go on with the scheme, as they still wanted to remain free to go back on their tracks. His answer was that he would make no report unless they were prepared to go ahead.

They then turned to a local engineer who was more amenable to their views. He got out a scheme, and after consideration it was agreed that it should be carried out. "Viewed in the light of to-day," Bailie Wightman continued, "it was not a bad scheme. It is quite true that ultimately we found that the buildings might have been erected of a greater height and a greater breadth, and this would have saved us the trouble and expense of taking a good part of them down."

In the staffing of the station, the Committee did not always follow the advice of the consulting engineer, nor did they allow the resident engineer after his appointment to guide them altogether in the subordinate appointments. In spite of these eccentricities, said the author, it is surprising to be able to say that the venture met with such success. He considers it due to the simplicity of the system, the three-wire continuous current, and the perfection of the plant.

Their experience of breakdowns was limited but peculiar, but before relating them, Bailie Wightman pointed out that they had had none during the last five years—at least, none that had come to the writer's knowledge. Once in their first year, when the Bailie was about to retire for the night, a message came from the Chief Constable that all the lamps were out. The Bailie 'phoned the resident engineer, and the answer received was that the "whole thing had burst up." Upon reaching the station, and not being able to get any satisfaction, the writer sent for the consulting engineer, who had the eastern end of the Burgh disconnected from the rest of the system, and set the installation agoing again. It was discovered next day that a slight breakdown in the insulation of one of the feeders near a junction box had caused all the trouble. "The results in the station were sufficiently alarming to cause the 'burst up' message. Alarming, indeed, to one who had never experienced anything of the kind before. A tremendous rattle and maddening whirl of machinery, a sudden flash, and lightning sparks upon the switchboard."

The next breakdown was also graphically described by Mr. Wightman, who added, "it would be more correct to call it a stoppage of supply." "One Sunday evening immediately following the lighting up for the night, through some cause which was not apparent, the lights gradually died away again into blackness. There being no sign of their going on again, the writer 'phoned to the station, and found there was something wrong with the engine. It would not go. On arrival at the station it was suggested by some one to put on the other engine, and in the act of doing so the cause of the trouble was discovered to be want of steam. The stop valve was examined next day, and found in good working order."

The author next referred with some bitterness to the effect which the first year's deficits of an Electricity Committee have on the Convener's chances in the November elections. Another trouble which was alluded to nearly lost the Bailie his seat. "Five and a half years ago our enterprise had reached a point when we needed to make a large extension, and the writer was severely heckled upon the contemplated expenditure. That same year, and at the same meeting, a charge was made against the department of gross extravagance in accepting an offer for goods which it was alleged could be had, and which had been offered at half the cost. In the contract in question, a certain class had been barred, and one tender which did not comply with the requirements was not put by the engineer in his report. When the figures were given and also the maker's name, the writer had to confess that he had never heard of the firm, knew nothing of the offer, and could give the meeting no satisfaction with regard to the charge, further than that he would strictly investigate the matter. A man was put up against him, but ultimately he did not go forward. The writer believes if he had been opposed on that occasion he would have gone down. The condition of the department at that particular time was critical and not strong enough to resist attack."

The Paper next referred with satisfaction to the successful efforts that were made by the Burgh of Govan to prevent the promoters of the Caledonian Power Bill and the Clyde Valley Electrical Power Bill from getting Govan included in their area of supply. The Burgh opposed both Bills, and the grounds of objection were identical: "Having set up under our statutory powers an electrical undertaking, and being able and willing to supply all the wants and requirements of the burgh in the matter of electricity, it would not be in the public

D

Digitized by Google

interest to subject the burghal undertaking to the evil effects of the opposition of a commercial concern—the more so as that company proposed to use our streets and roads for the purpose of the opposition."

After a fight which lasted for nearly three weeks the Committee, of which Sir James Woodhouse was chairman, threw out the Caledonian Bill, and passed the Clyde Valley, but excepted Govan and Partick on the other side of the Clyde, as well as three other towns. In the case of these towns power was given to lay mains through them. This power was refused in Govan unless with consent of the local authority. The author has no doubt that, although probably Govan would, in any case, have been excised from the Bill, it would have been placed similarly to Paisley, through which power was given to lay mains, but for its proximity to the city of Glasgow. Situated as Govan is, unless power was got to go through Glasgow there was no possible use of having such powers in Govan.

Up to that point in their history, the energies of the Burgh of Govan had apparently been directed chiefly towards lighting; as a matter of fact, the designation of the station as printed up on one of the gates was Govan Electric Light Station, and the Committee was known as the Electric Light Committee. The writer thinks that the promotion of the power companies, and their attempts to get a footing in the town, helped to give the Committee a proper view of their position and opportunities. When another extension was considered, they took a much larger and broader view of the situation. It also influenced them in making up their mind that they had come to the point when they might with advantage appoint an engineer with skill to advise them upon this extension, but one also with tact and experience to make the undertaking a commercial success. The usual course of advertising in the local and electrical papers was followed. From the replies received, and judging from their testimonials and experience, a long leet of ten was selected. The writer and another member interviewed the candidates upon the scene of their employment. They wanted to know both the men and their environment, to assist them in forming an opinion. The result was that they were able to present the names of five gentlemen, any of whom they felt confident would be equal to the position.

We give the remainder of Bailie Wightman's Paper in full :—

THE RELATION OF THE CONVENER AND THE ENGINEER.

This is a very interesting point in the development of an undertaking. To determine clearly the line of demarcation, how far and to what extent, the committee as represented by the convener should take part in carrying on the work.

Personally, the writer has no experience of public companies, and can speak with no authority as to the function of a chairman of directors. He can easily imagine that in many companies with a business, no greater than that of our undertaking, the chairman being a paid director with large private interests in the concern, he will take a fairly active part in the direction of affairs.

In a municipal concern the members of the committee are all to a greater or lesser extent engaged upon their daily avocations, and though in our town we have a healthy public spirit, it is too much to ask and more than should be expected, that a public man should give that attention to affairs which probably does obtain in public companies. In the writer's opinion we will best discriminate the relation between the committee and the engineer by determining first the duties and what we expect from the official. His duties as engineer require that he should report upon all proposals which involve capital expenditure, whether they have been initiated by himself or by any member of committee, with a view to their consideration, and when passed it is his duty to carry out the proposals into execution. As manager they involve his superintendence and supervision of the undertaking in all its departments. The appointment of his staff, or by delegation, all salaries and wages of the staff appointments to be approved by the committee.

The duty of the convener, on the other hand, at least so far as the executive part is concerned is purely honorary, and he will be a wise man indeed if he keeps it strictly so. There is nothing the writer can imagine more vexatious to an official than to find his committee meddling and interfering with the work of his staff. There are occasions when opportunity is given him of showing his interest and sympathy with them in their work. The circumstances of municipal management combine to make it absolutely necessary that a good understanding should prevail between the committee and the chief executive officer. This can only be attained if there be mutual sympathy on the part of the convener and the official, and in order to secure this it should be a necessary part of the engineer's duties to keep the convener constantly informed of the doings of his department. He should acquaint him with its progress and developments, and also with all disappointments or "regrettable incidents" which may have occurred. Complete confidence on the part of the chairman in the official, and reliance and trust on the part of the official in the chairman, are essential to success.

At meetings of his committees the convener is the spokesman of the official, and he should be in a position to afford explanations to his committee upon all the details of the work of the undertaking. He would be able to appreciate special difficulties and cases, and confer with and advise the official. Not only would the work of the committee be facilitated, but there is no doubt their joint work would result to the ultimate advantage of the enterprise under their care. When any matter is likely to be the subject of debate it is most desirable that the engineer and convener should know each other's minds with regard to it. They may not hold the same opinions, but it is most conducive to harmonious working if the head of the committee and the head official understand one another's position beforehand.

In conclusion, the writer would be very much at fault if he failed to refer to these annual conventions as being one of the most pleasant experiences of a convener. It is always an interesting thing to talk upon a subject, which one has very much at heart. It has been the writer's privilege for some years now to foregather with kindred spirits, representative of the municipal authorities from Exeter to Aberdeen, engaged in the same work, possessed with the same idea, giving and receiving sympathy, encouragement, and guidance, so that the undertakings which they direct may continue to flourish and be fruitful of much good to every community, and prove a source of strength to the nation.

DISCUSSION.

ALDERMAN PEARSON (Chairman of the Bristol Electricity Committee) said it was always a pleasure to him to attend these annual conventions, and to discuss electrical matters with other chairmen of committees. They had had their troubles in Bristol, but he had very little sympathy with the early remarks of the author where he spoke of getting a provisional order with a view to keeping somebody else out. He did not believe in a dog in the manger policy, and if any municipality had not the pluck to take up an enterprise itself, it should stand aside and make room for somebody else who was better able to do it. As an advocate of the extension of large borough boundaries, he rather thought, if he had been in Govan, he would have been inclined to lean upon his large neighbour, Glasgow, than to endeavour to have a small local station, but possibly looking at Govan from the outside and from the inside the circumstances would be somewhat different. So far as the consulting engineer referred to by the author was concerned, he thought he was wise in refusing to submit a scheme until he knew there was a probability of the work being carried out. Referring to Bailie Wightman's remarks as to breakdowns, Alderman Pearson said that at Bristol, in which city he was Chairman of the Electricity Committee, they had had a very severe fire, and as a matter of fact, to use Bailie Wightman's expression, the whole thing did "burst up" for the moment. The main switchboard was burned out, and for all practical purposes they were dead and gone for some hours. But he did not telephone anybody himself; they telephoned him, and having heard from various directions of the very terrible calamity, he early arrived at the conclusion that a chairman at the station would only be in the way, and that, further, if he had presumed to telephone or telegraph his engineer, his natural ability for blasphemy would be very materially increased. He therefore went to bed and waited until the next morning, when he sent to the engineer a message that when he knew anything about the fire and had anything to report, and had time to report it, he (the chairman) would call a committee and hear what there was to be said. He agreed heartily with the author as to the relationship which should exist between the engineer and the chairman. They had had the services of their engineer at Bristol since the works were first commenced, and he and the engineer had been working together ever since, a fact which had, in his opinion, gone for the good of the undertaking. He warned towns against being too ready to change either the chairman or the engineer under the impression that by so doing they might bring about an improvement. Concerning the author's reference to Parliamentary fights, the Bristol Corporation had had to fight a power company, which eventually was given the right to supply in Bristol under certain conditions. He had no fear of this competition, however, although it must not be assumed that because he had no fear of their competition he did not do his best, in the Parliamentary fight, to see that the possibility of it was reduced to a minimum. He certainly felt that whilst they could afford to treat their attacks with a certain amount of contempt it was wise to see that the attacks were minimised as much as possible, and although Bristol had failed to get total exclusion, they succeeded in putting the power company under such conditions that he should say their getting in was practically impossible. The company had had the powers for four or five years, and the only thing they were lacking to-day, and had been lacking for the whole time, was money. On the question of power supply, for the first two or three years in Bristol they had none, and after three years' working, they rejoiced in being in the position of having two motors, with an aggregate power of 4 h.p., and these two motors vegetated in Bristol for three years. Then, due more to pressure from outside than anything else, they were driven to develop their power load, and during the past seven years they had put on something like 7,000 h.p., which showed that a committee, not too energetic, could secure a power load, and in Bristol he certainly believed that, as time

Digitized by Google

went on, this would be one of their most profitable loads. At Bristol they also made the initial mistake which the author said was made at Govan, viz., they began in too small a way. Bristol had a population of 350,000, and they started with two 75 kw. sets. They thought this was as much as they dare go to, and in the summer months they were even frightened to run one of these to supply the comparatively small load; it seemed too extravagant, and they bought a 15 h.p. gas engine, which was solemnly installed under the advice of an eminent consulting engineer, to take the day load in the summer. What became of it he did not know. But they were not going to perpetuate that blunder of doing things on too small a scale. Where they found there was a likely load eight miles away at the mouth of the River Avon, where the new docks were being built, they thought it better to take the extra high tension cables the whole distance from the present station rather than to erect a small station to deal with the Avonmouth district. There would be a loss at the commencement, but in the end they believed the loss would be less than if they had dealt with this new load by the erection of a small station.

Bailie FINLAY (Member of the Glasgow Electricity Committee) said that at Glasgow they also began in a humble way, and when the question of the erection of works was under discussion about 14 years ago, they made a dreadful mistake. They were advised by the wise men of the West to go cautiously, and, consequently, a station was built in the centre of the town, and they paid £9 per square yard for the land. Some of them had preferred a station upon land where there were facilities for water, and rail accommodation for coal and ashes, so that it could be extended from time to time, but when this came before the Council, only three members supported it—himself, a gentleman who had had to leave the country for the country's good, and Bailie Robert Crawford. As pioneers, they were laughed at, but the laugh was on the other side 10 years later. The small station which was put up grew rapidly, and they had to build a new one. Now they had two large stations, one on the north side, and the other on the south side, of the river, the original station having been converted into offices for the electricity department. They were now supplying an enormous amount of electricity for power purposes, and had consumers taking 500,000 units per annum. Moreover, by this means they were gradually making the city free from smoke. He fully agreed that they should not interfere with the technical man at the head of affairs. In Glasgow they had a fire department, of which he was Chairman, and when there was a fire he did not rush out with a hose-pipe to try and put it out.

Col. SINCLAIR (Chairman of the Swansea Electricity Committee) said that, as Chairman of a small installation, he appreciated the troubles of the author. At Swansea they had not started in quite such a small way as some other towns, for they commenced with 500 kw.; with the advent of a power load, however, they soon outgrew this. He had spared no pains to push the power load, holding the opinion from the beginning that this was absolutely necessary to ensure success. In Swansea they had some very small and some very large power users, and they despised neither the half horse-power nor the hundred horse-power consumer. He agreed that when trouble arose at the works, the best place for the Chairman was at home in bed, and not at the works interfering with the man at the wheel. The relationship between a Committee and Chairman and their engineer should be of the closest kind, because the engineer had to depend on the Committee for policy, and he could not carry out his work in a proper manner unless he trusted his Committee, and took them into his confidence, and advised them in every possible way, so that really upon his advice they could shape the policy. He could not let the opportunity go by without once more impressing the great importance of a power load. With the advent of metal filament lamps, undoubtedly the revenue from lighting would be considerably less, and unless this was made up to a very large extent by increasing the power load, the effect would be bound to show itself in the balance-sheet. He advocated giving a power supply at the very smallest margin of profit, because if they got hold of a good customer taking a large number of units, it did not require very much profit per unit to give a handsome result at the end of the year. He felt that some Committees asked too much for power, and frightened the consumers away. In thanking Bailie Wightman for his Paper, he expressed the opinion that there should be two Councillor Papers at each convention, for the Chairman who came to these annual conventions desired to have the opportunity of discussing matters from the commercial standpoint.

Alderman SMITH (Deputy Chairman of the Liverpool Electricity Committee) thought that there was a possibility of Govan meeting with the troubles they had, even if an eminent consulting engineer had advised them. He was prepared rather to look upon the opinions of a man who knew the condition of things in the district for which he was advising, as being the more reliable than those of the man with a big name and a big reputation. He strongly believed in the continuity of Chairmen, and also in looking carefully to the advice of their own engineers, and giving them an opportunity of showing what they could do. In Liverpool they purchased a company's undertaking, and afterwards they took very much the line taken by Bristol, and put one big station some distance out of the town, where land was not £9 per yard, but three shillings and fourpence. They now had another station on a canal, and at both there were all the necessary facilities with regard to coal and water. In Liverpool the output of their undertaking had grown in 10 years from 1,500,000 units to 51,000,000 units, and he thought they might congratulate themselves on having made very considerable progress. Attendance at these meetings had resulted in adding to their knowledge on a good many things that they thought would add to the prosperity of the undertaking. They had tried hiring of motors, not with very much success up to the present, but it was growing.

Alderman BRODIE (Chairman of the Blackpool Electricity Committee) did not agree with the Paper, because his opinion was that there should not be little electrical undertakings. With regard to continuity of service, at Blackpool they had had five Chairmen in two months, and his own qualification for the chairmanship of the Electricity Committee was that he knew nothing about it. They had previously had a consulting engineer, an electrical engineer, and an amateur engineer, with the result that the undertaking had come almost to a standstill. But they had only had three engineers, viz., Mr. Hesketh, who was now in Australia, Mr. Quin, whose sad death they all deplored, and their present engineer, Mr. Furness. He could state that plant had been installed in their works at about £17 or £18 per kw., and within the past twelve months plant had been put in at as low a cost as £5 to £6 per kw., and, moreover, since Mr. Furness had been at Blackpool, the coal and oil costs had been halved, and they turned out between 60 per cent. and 70 per cent. more current.

Bailie MURRAY (Convener of the Edinburgh Electricity Committee) said that in Edinburgh they had received a lot of advice upon running their undertaking. One day a man came to him with a great idea, saying that a great economy could be made if they made the hole in the cable a little bigger; it would not then require so much pressure to get the electricity through. With such ideas prevalent, it was no wonder that conveners who did not know very much about electricity were sometimes a little at sea, and he was very heartily in accordance with the suggestion in the Paper that the Chairmen should restrict themselves to the business part of the undertaking and leave the engineers to themselves.

Alderman COATES (Chairman of the Hanley Electricity Committee) said that his experience as a Chairman for eight years, and a Vice-Chairman for fourteen years, had taught him that a a Chairman should always try to carry his Committee with him. Further, he should give his engineer credit for honesty of purpose and soundness of judgment, and then his engineer would not lead him far wrong. Many errors in their stations had been brought about through not trusting sufficiently the man at the head of affairs. He personally would not dream of interfering with the technical part of the work, but he had always been particularly anxious about the commercial side. He had come to the conclusion that some small stations would of themselves always prove very unprofitable undertakings. Good or splendid results could only be obtained with large undertakings. Taking the case in the Potteries, at Hanley they had a high-pressure alternating-current plant, but what they had lacked all through was a day load. Ten years ago, when the Light Railways Act came into force, Hanley, being a county borough, could have adopted it. But he could not carry his Committee with him on this point, although the running of tramways by the Corporation would have made the electricity undertaking a success. Instead of that, Hanley, being in the centre of six other smaller towns, failed to get co-operation between them, and consequently the North Staffordshire Tramways Co.'s light railway Order was passed, and the lines were run by the British Electric Traction Co. all through the Potteries. In the Potteries three or four electric supply stations had been erected, not one of them very remunerative, all within two or three miles of each other. If these were converted into one large station supplying 250,000 people instead of 60,000, as in Hanley, the success of the undertaking would be assured. He was glad to be able to say that the Potteries were trying to federate, and if they did, and could work upon the lines suggested, viz., to have one large station just on the borders, he did not think any commercial undertaking could be more successful than the supply of electricity in the Potteries.

Bailie JACKSON (Convener of the Partick Electricity Committee) did not agree that it was unwise to take the advice of a local engineer; he might have better knowledge of the district, and be a better guide than an expert from a distance. The Partick undertaking had grown at a very rapid rate during the five or six years of its existence. In Partick the output was 2,000,000 units a year, and they were in the privileged position of having all their streets and public buildings lighted by electricity. The power demand had grown rapidly during the past two or three years, and he thought they could claim to be in a fairly prosperous way as municipal undertakings went.

Bailie FISHER (Convener of the Paisley Electricity Committee) corrected Bailie Wightman in his reference to the Parliamentary decision upon the Caledonian and Clyde Valley Power Bills, and the power given to the latter to lay mains through Govan

Digitized by Google

with the consent of the Corporation. As far as Paisley was concerned, he said that the company had to prove before the Board of Trade that it was absolutely necessary to pass through with their mains before they could do so, and evidence was brought to show that from their Yoker power station the company could get to Johnstone at less expense than going through Paisley. He did not agree with some of the author's remarks. At Paisley they had spent £200,000 on the faith of their Provisional Order. They started with a load of 600,000 or 700,000 units a year, but it was now 3,800,000 units per annum. They had not been able to relieve the rates, and he hoped they never would relieve the rates, even when profits were made. The system had been changed from single-phase to two-phase, and the power load was being constantly added to. They also had a tramway load, and he believed the Partick undertaking would prove as profitable as any.

Bailie WIGHTMAN, in his reply, referred to the remarks made as to the employment of the expert. Some gentlemen seemed to imagine that all expert engineers were in London. That was not the case. They had got them in Scotland too, and the expert in question was not only a local, but an expert electrical engineer, even though local, and there was no doubt that he was in a line with experts at that particular time.

After a vote of thanks was accorded the author, on the motion of the President, the meeting adjourned to luncheon at the invitation of the Chairman of the Nottingham Electricity Committee, Sir John Turney, J.P. After some excellent speeches, and the drinking of the toast of Sir John Turney, the Mayor, and the Sheriff with musical honours, the car-sheds and repair-shops of the Nottingham tramways were inspected, and also the St. Ann's power house, which supplies part of the tramways and lighting load of the town.

On Wednesday the whole day was spent in an excursion to Matlock, Bath, and Dovedale. To-day (Thursday morning) the Annual General Meeting will be held, and this afternoon and to-morrow morning technical papers will be read and discussed. Members are also invited to inspect the electricity works at Derby, the Brush Electrical Engineering Co.'s works at Loughborough, the telephone manufacturing works of the British L. M. Ericsson Co. at Beeston, and some of the lace factories in Nottingham.

FOREIGN MANUFACTURERS AND BRITISH PATENTS

THE daily papers are just awakening to the importance of the new Patent Act, which received Royal Assent on August 28th last year. We published the contents of the Act at length last September, and again called attention to its new provisions and the procedure in connection with them in our first January issue, when the major part of the Act came into force; yet, in view of the attention that has recently been given to the "revocation" clause, the operation of which is deferred until August 28th next, we need make no apology for returning to the subject.

Hitherto it has been possible for a foreigner to patent an invention in this country as well as in his own, and the patent remains valid even if he does not manufacture here. In fact, if he had any reason for such a course, he could refuse to import the patented article into this country at all, and even in such circumstances he could proceed against anyone else who manufactured the thing. The Patent Act of 1902 gave anybody interested, and desirous of manufacturing under the patent, the power to put certain procedure into force to obtain a compulsory licence in such a case, but the provision has been practically a dead letter. The new Act of 1907, besides simplifying the compulsory licence clause, gives a more decisive means of action against a foreign inventor who has not manufactured in this country.

If, after four years of the date of the patent, the patented article or process is manufactured or carried on "exclusively or mainly" outside the United Kingdom, the patent is liable to be revoked, on application by "any person." In order that there should be no harshness under this Clause of the Act in the case of patents which were already four years old when the Act came into force, this provision only applies after August 28th next, so that the foreign patentee will have had a whole year to make the necessary arrangements for manufacturing in this country.

Germany and America have both protested against this clause, but public feeling is so strong in its favour that there is little likelihood of the Government sanctioning the principle of exempting any foreign country from its provision. Germany in particular has been persistent, for the first effect of the new clause will be upon a number of processes for the manufacture of dyes, patented by Germans, which have hitherto not been carried out in this country at all. The first effect upon the electrical industry will probably be upon the manufacture of metal filament lamps. Arrangements are already practically complete for the manufacture of tungsten lamps in this country by the General Electric Co., both under the Auer (Osram) and the Just Hanaman process, and the same is the case with other owners of British patents for foreign-metal filament lamps. In many cases there is no great urgency from the manufacturer's point of view, as the patents are not yet four years old, but the tantalum lamp would come under the action of this clause before the end of the current year if Messrs. Siemens have not completed an English works for its manufacture by then. Probably we shall hear more of the matter in the near future.

For the sake of completeness we give the "revocation" clause (Clause 27) of the Act in full:—

(1) At any time not less than four years after the date of a patent, and not less than one year after the passing of this Act (*i.e.*, after August 28th, 1908), any person may apply to the Comptroller for the revocation of the patent on the ground that the patented article or process is manufactured or carried on exclusively or mainly outside the United Kingdom.

(2) The Comptroller shall consider the application, and, if after inquiry he is satisfied that the allegations contained therein are correct, then, subject to the provisions of this section, and unless the patentee proves that the patented article or process is manufactured or carried on to an adequate extent in the United Kingdom, or gives satisfactory reasons why the article or process is not so manufactured or carried on, the Comptroller may make an order revoking the patent either—(*a*) forthwith; or (*b*) after such reasonable interval as may be specified in the order, unless in the meantime it is shown to his satisfaction that the patented article or process is manufactured or carried on within the United Kingdom to an adequate extent.

Provided that no such order shall be made which is at variance with any treaty, convention, arrangement, or engagement with any foreign country or British possession.

(3) If within the time limited in the order the patented article or process is not manufactured or carried on within the United Kingdom to an adequate extent, but the patentee gives satisfactory reasons why it is not so manufactured or carried on, the Comptroller may extend the period mentioned in the previous order for such period not exceeding twelve months as may be specified in the subsequent order.

(4) Any decision of the Comptroller under this section shall be subject to appeal to the Court, and on any such appeal the Law Officer, or such other Counsel as he may appoint, shall be entitled to appear and be heard.

A Long Lamp Record.—Mr. G. M. Boddy & Co. inform us that a 220-volt metal filament lamp of the type they sell has been burning in a sloping position in an electricity works for 3,170 hours, and does not show any serious blackening. The current is alternating.

Kent Collieries Electrical Plant.—In the Official Referee's Court before Mr. Muir Mackenzie on Monday last, the case of Ernest Scott & Mountain, Ltd., against the Kent Collieries, Ltd., again came up on the question of costs. The judgment, according to which the former company was awarded £2,945 as the balance of the contract price, and the latter company £1,117 on the counterclaim, was given on page 987 of our last week's issue. Mr. C. A. Russell, K.C., for the plaintiffs, held that the plaintiffs had been perfectly justified in bringing the action, and that defendants should pay all costs excepting as regarding that part of the counterclaim on which the defendants had won. Mr. Muir Mackenzie directed the plaintiff's costs of the claim to be taxed as if there had been no counterclaim, and the costs of the counterclaim, relating to those issues on which the defendants had succeeded, to be taxed and the amount deducted from plaintiff's costs.

THE G.B. SURFACE CONTACT SYSTEM ON THE L.C.C. TRAMWAYS

THE circumstances which led up to the decision of the London County Council last July to adopt a surface-contact system for the Aldgate and Bow section of their tramways have been dealt with in our columns from time to time (see ELECTRICAL ENGINEERING, Vol. II., July 25th, p. 124). The conduit system in use on the Council's other lines could only have been installed in a modified form and at great expense on account of the very small available depth under the roadway over the tunnels of the Whitechapel and Bow Railway, and the ordinary overhead trolley construction was ruled out of court by the refusal of the Stepney Borough Council to allow its erection, although in the neighbouring district of Poplar no such objection was upheld. Recourse was therefore had to the surface-contact system designed by Messrs. Griffiths and Bedell, which has been running with so much success on a smaller scale for more than two years at Lincoln, and previously on an experimental line at Ilford. It was possible to install this system without difficulty within the minimum limits of depth available, and the additional equipment required on the cars could be fitted without interfering with the provision for the plough and trolley of the cars intended for through running on to sections equipped on the conduit or overhead systems (see ELECTRICAL ENGINEERING, Vol. II., p. 107). The cost of installation of the system is considerably less than for the conduit system, but, of course, exceeds, though not greatly, that of the overhead trolley. The comparative costs of maintenance on such a busy route as between Aldgate and Bow remains yet to be seen, although, judging by experience at Lincoln and the simplicity of the system, this is not likely to be heavy. Details of the working costs for the short line at Lincoln for the first year of working were given in ELECTRICAL ENGINEERING, Vol. II., p. 163.

The system as installed on the L.C.C. tramways differs but little in the equipment of the track from that of the pioneer line at Lincoln, but some modifications have been introduced into the arrangement of the collecting gear on the cars owing to the presence of the plough for through running on the conduit lines. The principal feature of the system is the provision under the studs in the road of a bare feeder cable partly of magnetic material supported on insulators in an earthenware pipe. The body of each stud contains a plunger normally held up by a spring, which, however, becomes magnetic and attracts itself down to the cable and makes contact with it when the powerful magnet on the car passes over it. The heads of the studs are of cast-iron, and are sunk into granite blocks, so that they do not project appreciably above the surface of the roadway. The action of the flexible chain which forms the actual collector on the car is somewhat similar to that of the plunger within the stud. Lying normally clear of the road surface in a groove in the surface of the wide pole face of the car magnet, it is attracted down to the iron stud-head and makes contact as it passes over. The plungers in the studs are provided with carbon contacts, although they are not usually required to break the circuit, as the studs are so spaced that the collector does not leave one stud before it has made contact with the next in front.

The general arrangement of the conductor and studs is seen in Fig. 1. The principal differences from the Lincoln equipment lie in the different shape of the earthenware pipe containing the conductor, which is made of an egg-shaped section instead of being circular as at Lincoln, and in the slightly reduced overall length of the studs, which are 1 in. shorter than at Lincoln. The studs are also spaced 6 ft. apart instead of 9 ft., owing principally to the fact that the presence of the plough carrier on the cars only permits of a portion of the car length being available for the collecting apparatus. The available depth above the Whitechapel and Bow tunnel was almost everywhere sufficient for the installation of the equipment, but at one place the level of the roadway had to be raised about 2 in. over a short distance.

The pipe itself is of vitrified stoneware of 5 in. horizontal internal diameter and 6 in. depth; the shape of its section is shown in Fig. 1. It is laid in concrete, and great care has been taken with the jointing. Ordinary duct strip is first placed round the pipe, and a sheet-iron former is then placed over the joint and bitumen poured in. The formers are, however, not removed. Every alternate length is provided with a T projection, on to which is fitted the short, vertical earthenware tube accommodating the body of the studs. The total overall depth of the tube below the rail level does not exceed 17 in. Fig. 2 shows the arrangement of the access boxes which are provided for drawing in the cable at intervals varying from 200 to 400 yd. Drainage pipes are taken from the access boxes, and also from points on the pipe between them, to a concrete sump at the side of the road, as shown in Fig. 3. It has not been thought necessary to connect these sumps to the sewers, as very little water can find its way into the conduit pipe.

The conductor cable itself is of a special construction, as its magnetic properties have to be considered as well as its electrical conductivity and suitability for making contact with the stud switch. The overall diameter of the cable is 1-3/16 in. It consists of a layer of copper strands over a jute core, and then a layer of galvanised iron strands. The external covering consists of a series of iron sleeves 6 in. in length. The smooth, cylindrical surface obtained in this way is found to give a better contact with the carbon block of the switch plunger than the plain stranded cable which was originally employed at Lincoln. The sleeves are simply threaded on to the cable, and not in any way joined together, so that the cable is still sufficiently flexible for convenient drawing in. The cable is laid in lengths of from 130 to 150 yd. The conductivity of the cable is equal to that of a No. 00 trolley wire. Heavier currents could be carried in a cable of the same size by putting in more copper strands and diminishing the jute centre. The insulators upon which the cable is supported are made of vitrified glazed earthenware, and are placed at intervals of 6 ft. immediately under the studs. They are mounted on horizontal galvanised iron pins fixed in the conduit pipe, as shown in Fig. 1. Their form and method of support enables them to act as rollers when the cable is drawn in or out. The arrangement of the access boxes has already been shown in Fig. 2, which illustrates the methods adopted at the section insulators. The coiled up portions of the connections that will be noticed are for the purpose of allowing a certain amount of end-wise movement of the cable when it is desired to expose fresh portions to the stud-switch contacts. The arrangement of the feeders is practically the same as on the L.C.C. conduit lines; one of the insulators is shown in Fig. 4. The feeder cables are run at the side of the street, and connections are brought at intervals to the junction boxes through iron pipes. The working conductor is divided into half-mile sections in the usual way. It will be noticed that the insulator pins are each brought out at one end through the side of the pipe. These projections are bonded together with an earthed iron strip in the ground alongside the pipe. This arrangement,

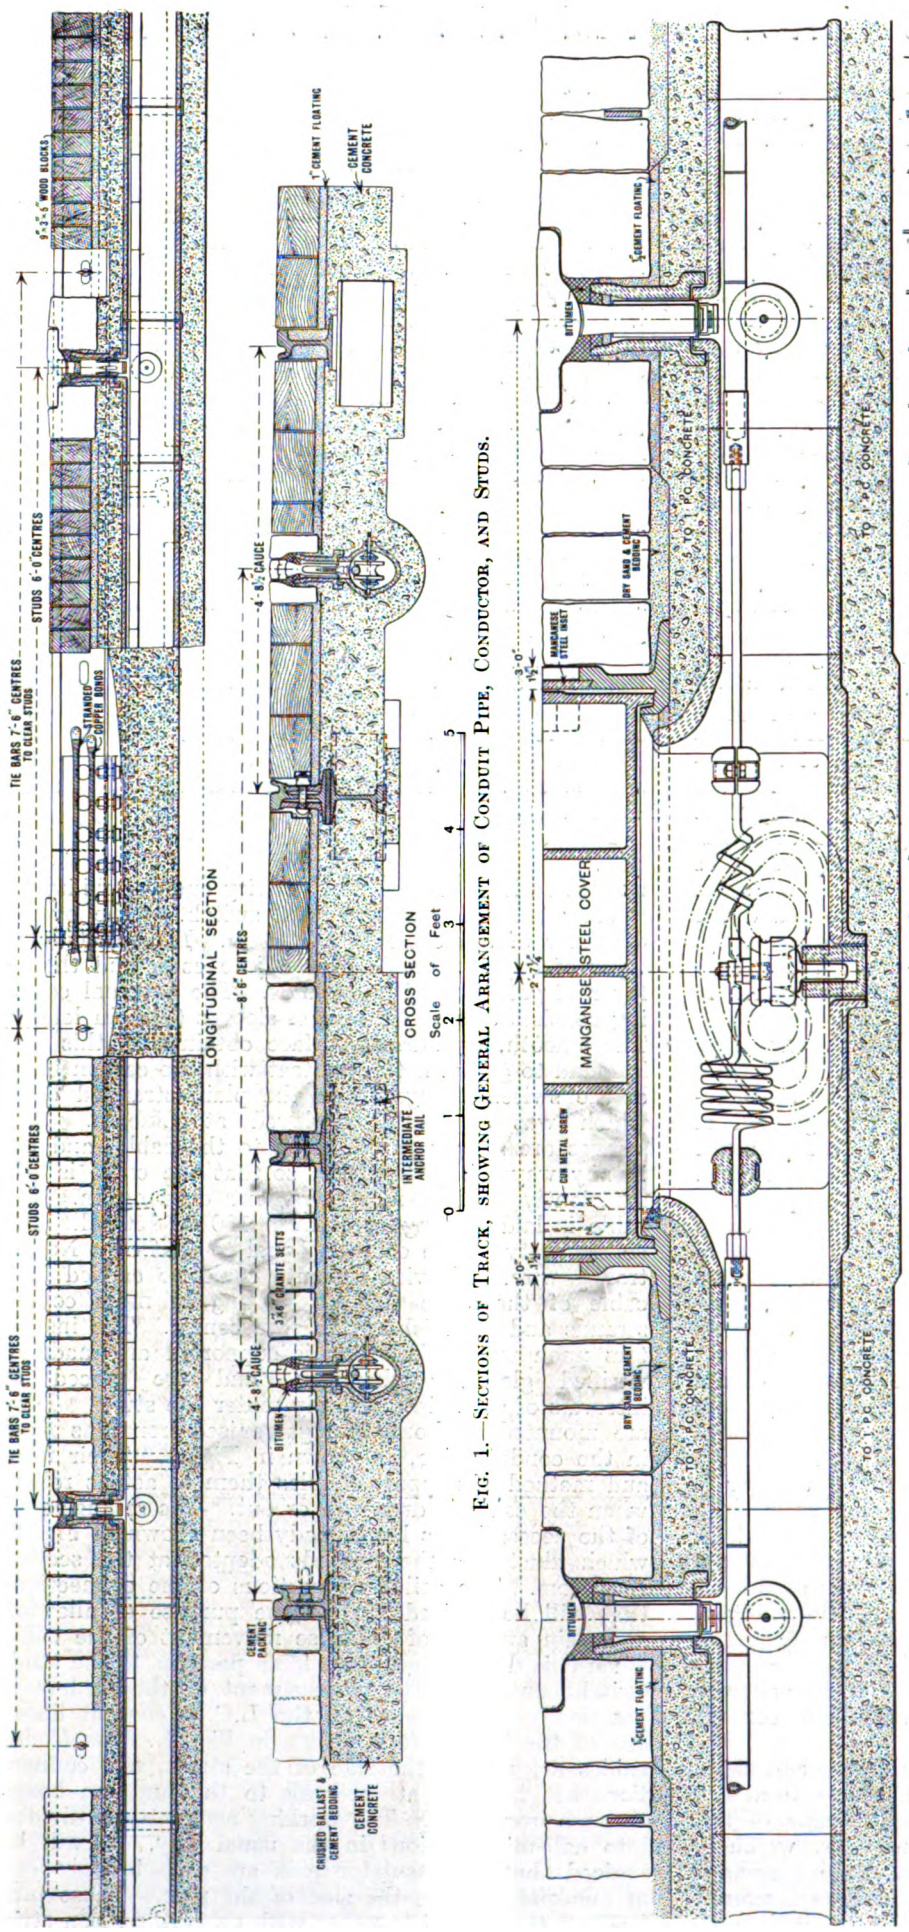

FIG. 1.—SECTIONS OF TRACK, SHOWING GENERAL ARRANGEMENT OF CONDUIT PIPE, CONDUCTOR, AND STUDS.

FIG. 2.—SECTION THROUGH ACCESS BOX.

Digitized by Google

which was used at Lincoln, is found to diminish osmotic effects on the insulators and to obviate trouble with leakage due to this cause. The conduit pipe is shown in place in Fig. 5.

The most interesting portion of the track equipment is, of course, the stud itself; a section of the standard stud as used on the L.C.C. line is shown in Fig. 6. The head of the stud is of cast-iron, with a chilled surface 10 in. long and 2½ in. in width. The surface is only very slightly convex, and is practically flush with the granite block into which it is recessed. The body or stalk of the stud is of soft iron, and is attached by a bolt to the head. The lower part of this forms a fork lined with brass. Between the prongs of this fork is suspended the iron switch plunger, which is the only moving part of the track equipment. The movement is limited within a certain range by a pin through the prongs of the fork which passes through a slot in the moving plunger. The iron part of the plunger is enamelled as a protection, and, as we have already said, is provided with a carbon contact block at its base. The carbon contact piece is held in a copper clip, which also extends up the sides of the plunger, and to which are attached flexible copper connections for taking the current to the stud-head. Considerable care has been taken in the design of the helical springs by which the plunger is held up clear of the cable when not magnetised; the making of the stud "dead" after the car has passed depends entirely upon their action. The springs are made of steel piano wire heavily coated with copper, and further covered with a preservative compound. The maximum possible extension to which they can be subjected is well within the elastic limit, and exhaustive experiments have been made equivalent to the extensions that would be experienced in a 20 years' service, but no appreciable alteration in the elasticity was found. The action of the plunger in being, so to speak, repelled by the fork is interesting from the magnetic point of view, and has been the subject of experiments by Prof. J. T. Morris, who has investigated the distribution of magnetism and the force on the plunger (see ELECTRICAL ENGINEERING, January 2nd, p. 7). Under working conditions, the flux density near the end of the fork is about 4,000 lines per sq. cm. Fig. 7 shows the granite blocks for the reception of the studs in position before the paving is completed, and the manner in which the studs can be inserted and withdrawn complete is shown in Fig. 8. When in place, the entry of water into the conduit is prevented by pouring bitumen round the stud.

In addition to the standard studs described above, a few studs of another type are used near junctions and at similar places where there is a possibility of

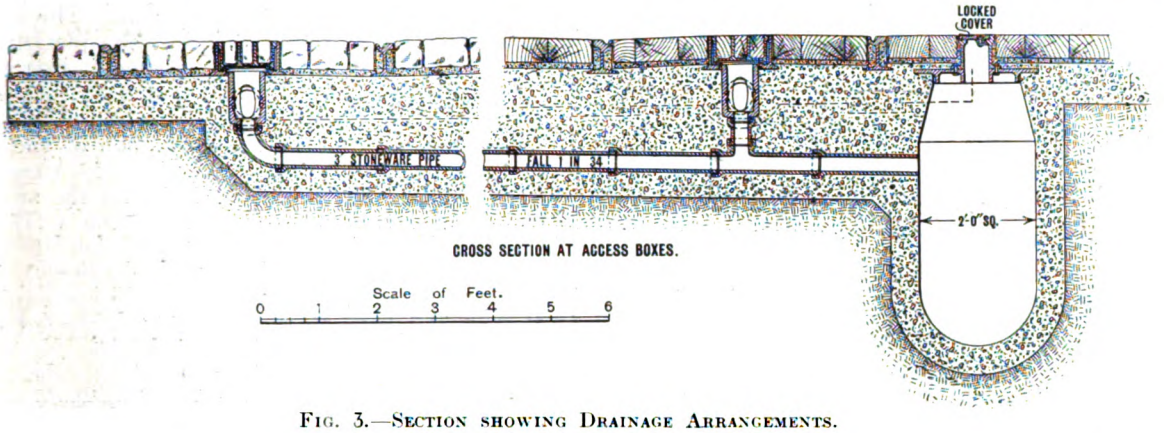

FIG. 3.—SECTION SHOWING DRAINAGE ARRANGEMENTS.

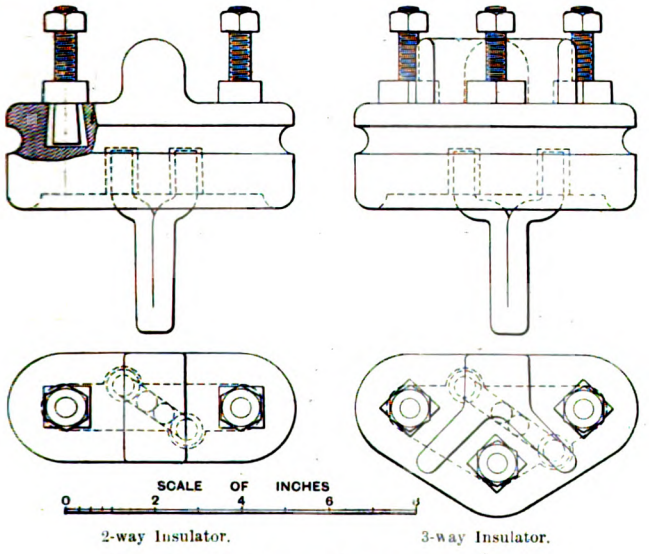

FIG. 4.—DETAILS OF FEEDER INSULATORS.

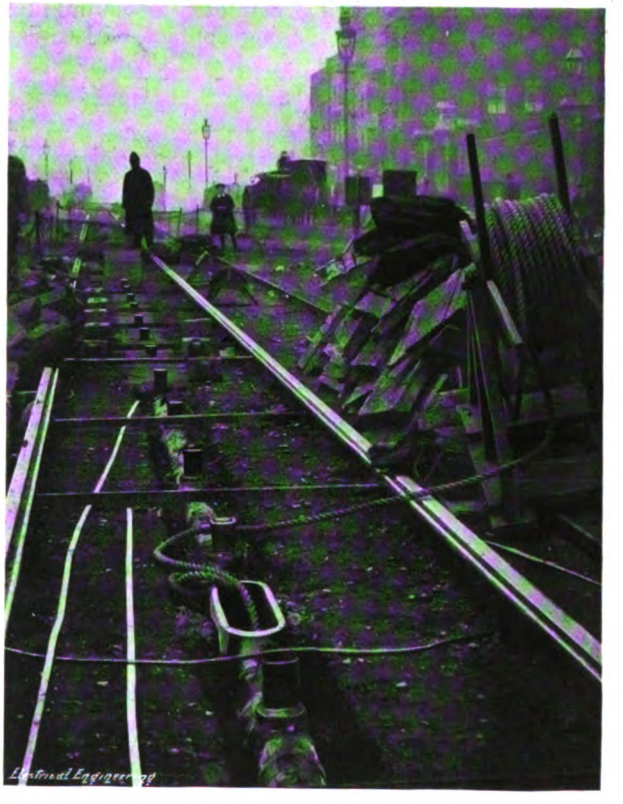

FIG. 5.—VIEW OF TRACK UNDER CONSTRUCTION, SHOWING CONDUIT TUBE IN PLACE.

Digitized by Google

pieces of scrap-iron, &c., being picked up by the magnetic collector on the car and caused to trail across the rails and studs so as to form a short circuit. In these special studs, a section of one of which is shown

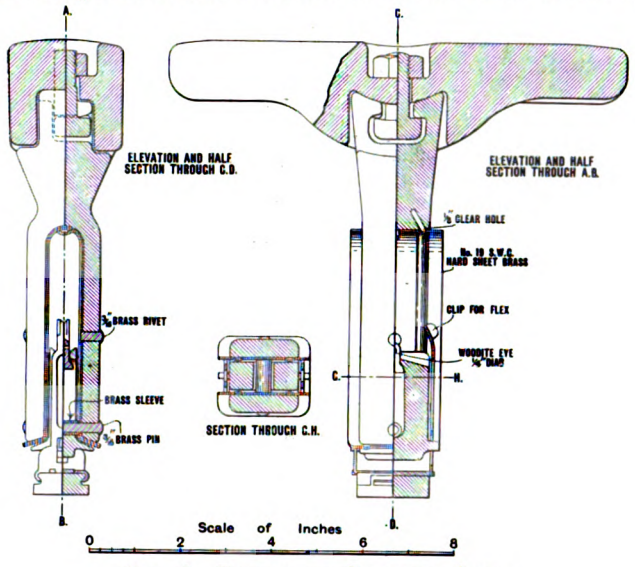

FIG. 6.—DETAILS OF STANDARD STUD.

in Fig. 9, the head is insulated by mica from the lower part, and connections are taken to a resistance of about 8 ohms contained in a pit, so that the short-circuit current is limited to about 60 amperes. About 100 of these resistance studs are required on the section under consideration. In order to avoid the flexible collector being attracted down and producing short circuits by making contact with rails at

FIG. 7.—TRACK UNDER CONSTRUCTION, READY FOR PAVING.

crossings, short sections of rail of a special manganese steel, consisting of about 88 parts of iron to 12 of manganese, and with a permeability of only about $\mu = 1{\cdot}4$, and therefore practically non-magnetic, are employed. It may be said here that the leakage is not any greater per mile of track than with the ordinary conduit system. At Lincoln, for the three miles of single track, it is under 0·2 ampere.

At Aldgate, where the junction occurs with the conduit lines, a short length of both the up and down line is provided with both forms of construction, the surface contact studs remaining in the centre of the track with the conduit to one side. The conduit is arranged to form a loop, so that the plough of a car which has approached from the conduit line can, after being detached, be led round and fixed to a returning car on the other track.

The contract for the reconstruction of the track on the three miles of route was given to Messrs. Dick, Kerr and Co., but all the material for the surface-contact equipment was supplied by the G.B. Surface Contact Co., under whose supervision it was laid. The total value of the contract was £79,850, including cables and ducts (but not including car equipments). Messrs. Bolckow, Vaughan and Co. supplied the rails; the special work was from Hadfield's Steel Foundry

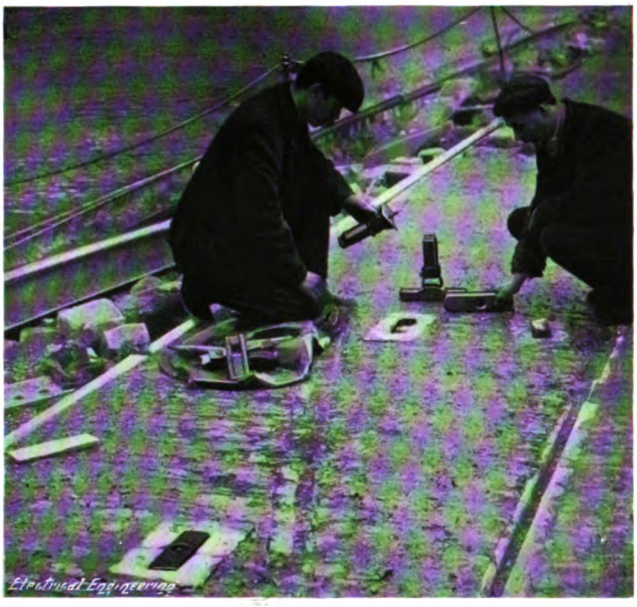

FIG. 8.—INSERTION OF STUDS.

Co., and the Western Electric Co. supplied the cables. It may be mentioned here that the London County Council will pay a royalty of £500 per mile to the G.B. Surface Contact Co., and have the option of retaining or rejecting the system at the end of one year. The street work was commenced last October, and has been complete for some time, but a service of cars was only started last week.

The G.B. equipment is being fitted to 48 double-bogie cars of the L.C.C. standard type, all of which will eventually be provided with the plough apparatus for through running over the Council's slot conduit lines. This through running, however, has not yet been commenced, as the combined equipments are not quite ready. A few cars have been equipped with the G.B. collecting gear without the plough in order to save time, and a service over this part of the lines is thus being maintained for the present. The presence of the plough fittings have, as already remarked, considerably shortened the length available for the collecting chain which has to be fitted at one end of the car owing to the necessity of a clear space right across the car for the sideways movement of the removable plough carrier. This, as we have seen, has entailed the studs being placed a good deal nearer together than at Lincoln, and, of course, an entirely new design of magnet and collector had to be got out

Digitized by Google

which required some care in scheming in order not to interfere in any way with motors, brake equipment, and plough carrier.

A general diagram of connections of the car equipment is given in Fig. 10. The principal items are the magnet within which is the contact chain, about which more will be said hereafter, a small battery of accumulators by which it can be excited before making contact with a stud, and a live-stud detector with automatic switch. The battery is arranged so that the current through the motors assists the battery in energising the magnet, and when above a certain value recharges the battery. The live-stud detector simply consists of a short auxiliary collector at each end of the car in circuit with an automatic cut-out which breaks the motor circuit when a stud which has remained alive after the main collector has left it is passed over.

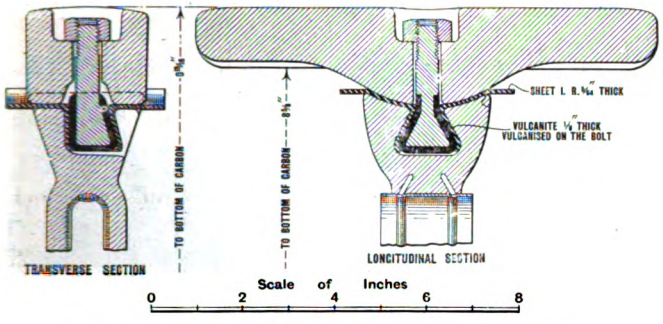

FIG. 9.—DETAILS OF HEAD OF RESISTANCE STUD.

The magnet has the field coils on horizontal yokes connecting the long pole-pieces ladder fashion. The pole containing the collecting chain is, of course, in the centre of the car, and the magnetic flux therefrom passes through the earth and through the studs and back to the other pole at the side of the car. The magnet is rigidly attached to the unsprung portion of the truck by insulating bolts, and is arranged with a clearance of about 2 in. above the roadway; the excitation required by the magnet is about 11 amperes at 18 volts.

The collecting chain consists of a series of special shaped iron links, each 5 in. long, strung on to and clamped with set-screws to a steel wire rope, the ends of which are secured to extensions of the magnet pole. A series of springs normally hold these links up, but when passing over a stud they are pulled down by exactly the same magnetic action that causes the switch-piece in the stud to descend into contact with the cable, in the manner shown in Fig. 11. The actual pull between the chain and the stud is adjusted at from 2 to 3 lb., and the tractive effect is negligible, as it does not exceed a few ounces. The general arrangement of the collector magnet is shown in Fig. 12.

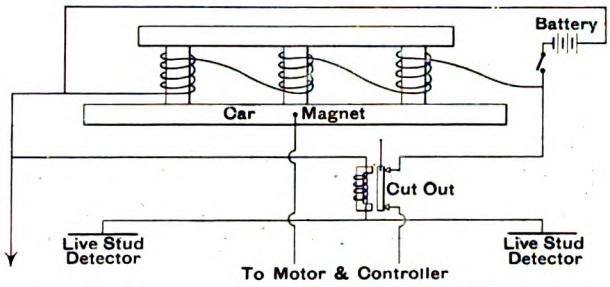

FIG. 10.—DIAGRAM OF CONNECTIONS OF CAR EQUIPMENT.

FIG. 11.—SKETCH SHOWING ARRANGEMENT OF CONTACT CHAIN.

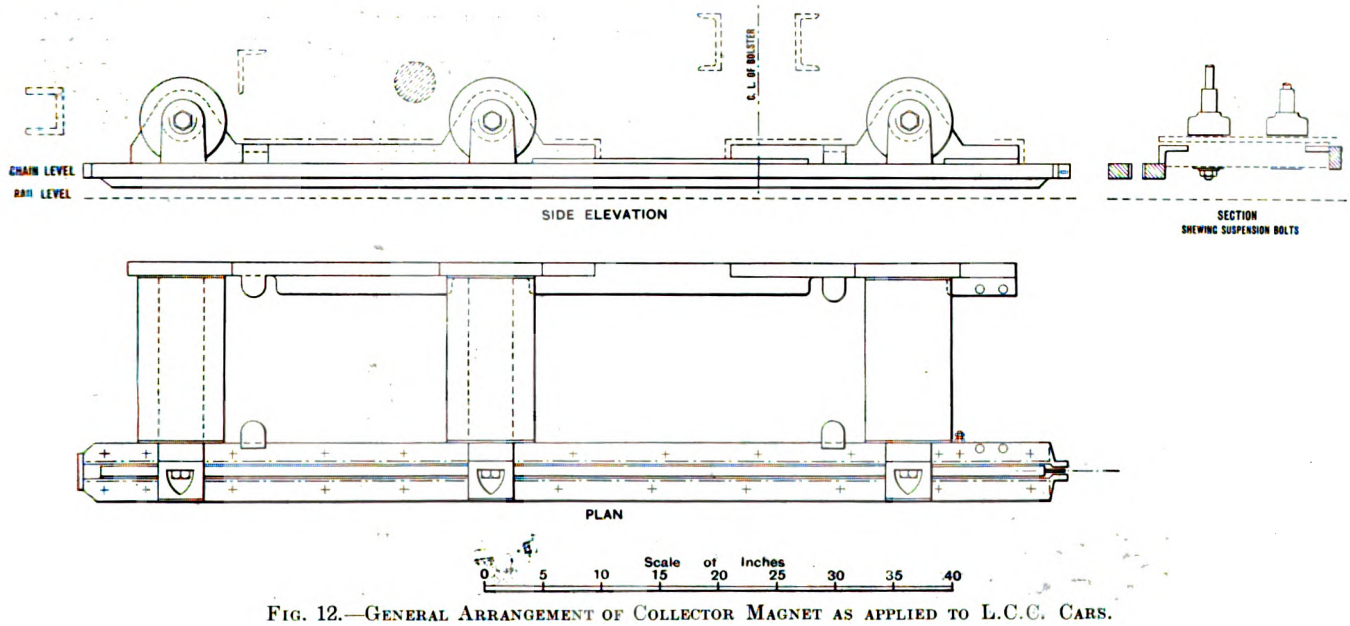

FIG. 12.—GENERAL ARRANGEMENT OF COLLECTOR MAGNET AS APPLIED TO L.C.C. CARS.

The permanent way and track work has been carried out to the designs of Mr. Maurice Fitzmaurice, C.M.G., Chief Engineer to the London County Council, and the electrical part of the equipment has been under the supervision of Mr. A. L. C. Fell, Chief Officer of Tramways to the Council, and Mr. J. Rider, Electrical Engineer to the Tramway Department.

Wireless Telegraphy.—H.M. Commercial Attaché at Yokohama (Mr. E. F. Crowe) reports that arrangements have been completed for wireless telegraphy at Choshi in Shimosa Province, near Cape Inuboe, the most easterly point in Japan, and that messages can be despatched to vessels within 120 nautical miles of the station. The charges are treble the ordinary land rates, or double if the telegram does not pass over the land wires. It is intended to establish public wireless stations later at Shiwomisaki in Kishu, Osezaki on the Goto Islands, and on Tsunojima in Choshu. The steamers on which the apparatus has been installed are those of the Nippon Yusen Kaisha and Toyo Kisen Kaisha, which sail to America.

GERMAN SHIPBUILDING EXHIBITION

Exhibits of the Felten & Guilleaume-Lahmeyerwerke A.G.

AT the German Shipbuilding Exhibition now being held in Berlin, the Felten and Guilleaume-Lahmeyerwerke A.G., of Frankfurt, have several exhibits representing some interesting applications of electricity on board ship. One of the most striking of these is a model of the Adam system for coaling warships at sea. The principle of this system is shown diagrammatically in Fig. 1, in which the warship is assumed to be tugging the collier by means of a hawser. The endless cable, *d*, is carried round the cable sheave, *r*, which keeps it in motion, and also round the pulleys *e*, *f*, *g*, *h*, *i*, the tension pulley, *a*, and the pulleys fixed to the decks of the two ships. The cable

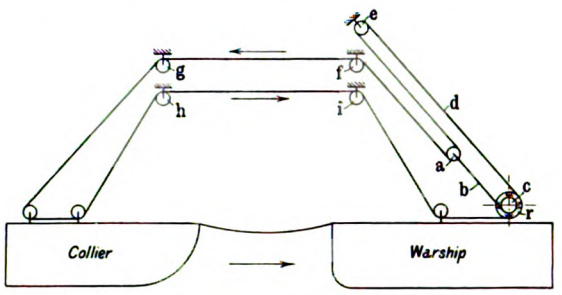

FIG. 1.—DIAGRAM OF THE ADAM COALING SYSTEM.

sheave *r* is mechanically coupled to the magnet system of the motor, and the cable is kept continuously moving in the direction indicated by the arrows. Both the field-magnet system and the armature of the motor are capable of rotation, as can be seen from an inspection of Fig. 2, which shows the motor with cable sheave and drum complete. The pinion on the right of the figure is connected to the magnet system, and drives the cable sheave, while the pinion on the left is connected to the armature and drives the drum *c*. To this drum is attached one end of the tension rope *b*, the other end being fixed to the tension pulley *a*. When the motor is switched on, the magnet system rotates, keeping the endless cable moving. The armature exerts a definite torque, and rotates in the opposite direction, winding in the tension rope *b* until the pull on this is equal to the torque of the armature. If the distance between the ships increases the pull on the tension rope overcomes the torque of the armature, and some of the rope is unwound. If, on the other hand, the ships approach one another, more of the rope is taken in, and so the endless cable is kept at a fairly constant tension. These actions are quite automatic, and the apparatus responds quickly to alterations in the distance between the ships. Where the cable leaves the ship, it passes through a fixed metal cone (coming out at the apex of the cone). A running noose made from a loop of stout cord is slipped over the cone and attached by means of a small iron hook to the full or empty sack, according to whether the cable is leaving the coaling vessel or the warship. The sack is pushed forward and the noose slips off the cone on to the cable. The weight of the sack draws the noose tight and the sack is carried along to the other ship. The cable is drawn so tight round the pulleys, that when the sacks pass the pulleys there is no chance of the cable being pulled off. At the receiving end, the cord supporting the sack is cut by two knife edges, just before the sack touches the deck. The whole apparatus takes up little room, and on account of the method of bringing the cable down to fixed pulleys on the far

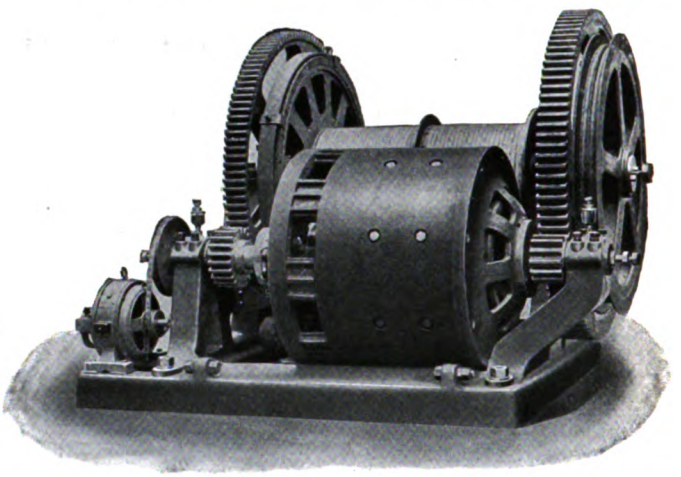

FIG. 2.—ADAM COALING WINCH.

sides of the masts, the tension on the masts themselves is not very great.

The turbo-generator illustrated in Fig. 3 is of especially compact and light construction for lighting and power supply on board ship. The turbine is a five pressure-stage Zoelly turbine, constructed by Escher Wyss & Co., of Zürich, and rotates at 3,600 revs. per min. An extra inlet valve is supplied, by means of which live steam can be admitted at the third pressure stage, and the continuous output increased to 25 per cent. Speed regulation is effected on the "servomotor" principle, by throttling the steam at the inlet valve. With this arrangement, on suddenly taking off the load, a speed variation of at most 4 per cent. is obtained. A further safety device is provided, which closes the inlet valve directly the speed exceeds the normal by 10 per cent. The continuous-current generator is a 220-volt 65-kw. machine. On account of the high peripheral speed, the commutator is constructed in two sections. Carbon brushes are used. Forced lubrication at a pressure of two atmospheres is provided, and the oil is cooled by circulating water in the tank under the bedplate.

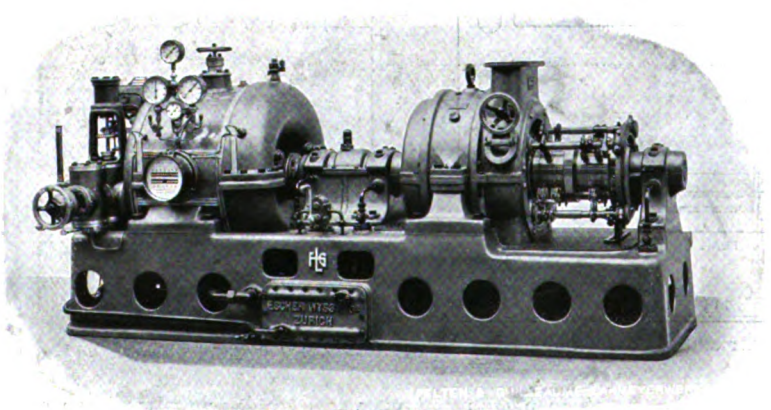

FIG. 3.—65-KW. ZOELLY TURBO-GENERATOR.

FIG. 4.—6 H.P. MOTOR-GENERATOR.

Another interesting exhibit is a motor generator especially designed for supplying searchlights. The generator will supply a constant current of from 150 to 200 amperes at from 0 to 60 volts, independent of the resistance of the external circuit. The

Digitized by Google

motor is an ordinary shunt motor, but the generator, although a two-pole machine, is supplied with four sets of brushes; the brushes from which the current are taken for supplying the lamp are in the neutral zone, as usual, but the auxiliary brushes are at right angles to these, and each of the two field windings is connected across from a main brush set to an auxiliary brush set. The poles are divided in order that the auxiliary brushes shall not lie in a strong field. A winding connected across the mains produces a constant field in the armature axis, and another series winding producing a field in the same axis, carries the load current. The value of the constant current is altered by varying the number of turns in this last series compensating winding.

A compact construction for a motor generator for supplying alternating current to the wireless telegraph installation is illustrated in Fig. 4. The set consists of a 6-h.p. 1,500 r.p.m. shunt motor, and a 50-cycle single-phase generator developing 3·6 kw. with a power factor of 0·6. The generator voltage can be varied in 28 steps from 20 to 110 volts.

Ventilating fans, crane and hoist controllers, and various signalling systems are also exhibited, and examples of telephone, telegraph, and power cables are shown by the cable department.

THE KJELLIN AND RÖCHLING-RODENHAUSER ELECTRIC INDUCTION FURNACES

AT the last meeting of the Faraday Society, Mr. J. Härdén contributed an extremely interesting Paper upon the "Electric Induction Furnace," mainly in connection with the Röchling-Rodenhauser modification of the Kjellin furnace. In working with the original Kjellin furnace some disadvantages were experienced when dealing with large amounts of material, for instance, with charges of three tons or more. In such cases the section of the bath becomes very large, thus causing a low resistance and a consequent decrease in the power factor. If it is tried to increase the resistance by making a ring of wide diameter and small section, the distance from the primary becomes greater and the power factor is again lower. Consequently it was found necessary to employ a generator of very low periodicity for such furnaces, and this, of course, is not desirable. Furthermore, the processes of desulphurisation and dephosphorisation become very tedious, because it is difficult to keep the slag sufficiently liquid for such purposes. Nevertheless, this class of furnace will still hold its own for making special crucible steels, because for this purpose it is almost ideal.

In the case of crucible steel, it must be remembered, we rarely have to deal with more than one ton, or at the most one and a half tons at one time, and as it does not pay to use crude raw material no actual refining is required, but simply melting and "killing," and for this class of work plain induction furnaces can be used which will answer very well at 15 to 25 cycles per second. But for refining material smelted from inferior ores which still contain from 0·1 to 0·2 per cent. of sulphur, and 0·05 or more of phosphorus in quantities of from 5 to 7 tons, it was found necessary to modify the furnace. The modified furnace is a transformer furnace with two ring-shaped baths adjacent and communicating with one another, in case of a single-phase furnace, and three such baths in the case of a three-phase furnace. The hearth is square or rectangular, and is placed in the centre between the rings with doors both at the back and front. In exterior appearance it is very much like the Siemens open-hearth furnace, but the principal feature is the heavy secondary winding of copper cables wound round the primary and conaxial to it (one on each leg of the core), surrounded by the rings forming the charge. These copper secondaries which consist of only a few turns are connected to conducting plates—which one can hardly call electrodes, for reasons which we will give immediately—built into the furnace wall, two in front, and two at the back for single-phase furnaces. They consist of corrugated cast steel plates and a compound of magnesite and dolomite, and tar is applied firmly over the corrugation. When cold these plates do not conduct well, but as soon as the furnace is charged with molten raw material they function as a conductor of the "second class," and readily allow the passage of the current. About half of the power is transmitted to the charge by induction in the rings and the rest of the power through the side plates. As the copper

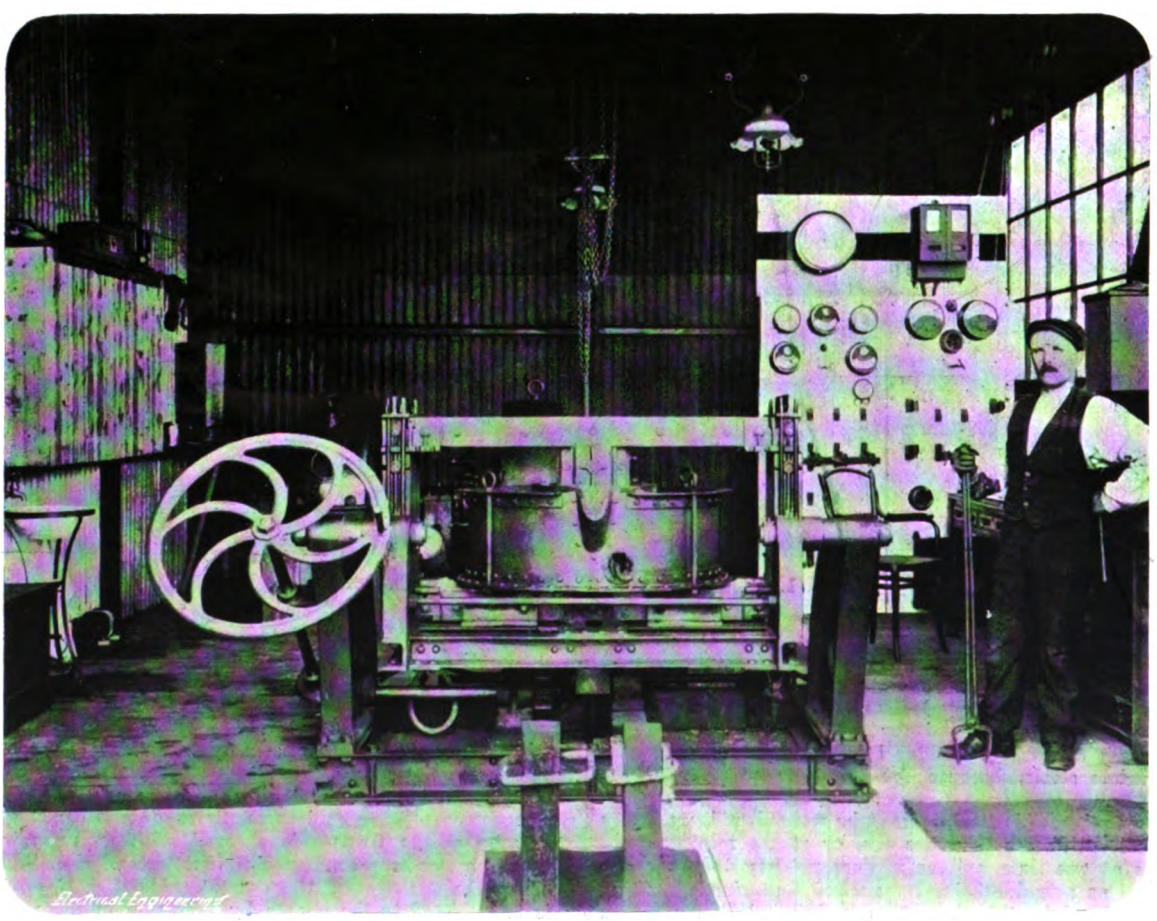

FIG. 3.—EXPERIMENTAL KJELLIN FURNACE AT BATTERSEA.

Digitized by Google

secondary is placed very near to the primary, the leakage field is very much smaller, in fact, three furnaces for one to one and a half tons are now in operation with 50 periods at a power factor of 0·7 to 0·85; such a result could never be obtained with a plain induction furnace of a similar size, in spite of "bifilar" baths and other devices which have been tried. A still more important gain is in the metallurgical possibilities which can be obtained with the new design. For the carrying out of any refining processes in steel we must have a sufficiently liquid silica, and be able to handle the same. This is to a certain extent obtained in some "electrode furnaces," where an arc plays between carbon blocks and the slag blanket. Sometimes, however, this proves troublesome owing to the temperature being extremely high at the spot where the arcs are playing, and for some classes of steels this is a distinct disadvantage. If the carbons are dipped directly into the molten metal they are at once consumed, and the steel becomes contaminated.

With the combined furnace just described the conducting side plates are of quite a neutral nature, as they are practically not corroded. In one case, for example, where the furnace had been in use, day and night, for three months, the plates were so little corroded that the amount calculated per ton of steel could hardly be determined. Part of the power is induced in the rings, thus heating the charge, and the rest passes through the side plates only to such an extent as has been proved by experience to be necessary in order to obtain a sufficiently liquid slag. The ring-shaped part of the bath is covered with bricks, the height being slightly below the level of the charge in the centre bath, consequently no slag can enter into the rings, and as it is the slag which is injurious to the lining, the rings need hardly any repair during a long run, whereas the rectangular bath in the middle is easily accessbile and can be easily repaired.

It is evident from what we have stated that the steel side plates are not really a return to the old system of electrodes, because practically no consumption of these plates takes place. Before using the furnace the lining is first stamped in, the tar is burned out either by heating a cast steel ring or by pouring a small quantity of pig iron into the hearth. The pig iron is then teamed for treatment in the Bessemer converter, and a fresh charge is given which is tapped direct from the converter. It is found more economical to burn out the carbon and the silicon in the converter before refining from phosphorus and sulphur. Burned lime is added to form a suitable slag, the slag only containing about 6 per cent. magnesia, and, if necessary, a small quantity of fluorspar is added to act as a flux, and plate scale from the rolling-mill for decarbonisation. The slag takes up the phosphorus very readily, and it is then made more viscous by the application of cold lime and drawn off through the slag door by slightly tilting the furnace.

When the dephosphorising is finished the first slag is entirely removed, a fresh one consisting of lime alone is formed, and this, when the temperature is raised, acts as a desulphuriser. The oxygen is also driven out in this operation partly by the addition of small quantities of ferro-silicon and partly by calcium carbide, which is presumed to be formed *in situ*. Finally the maximum power is given in order to drive out the last trace of oxygen, and as soon as no more gas bubbles are seen to leave the charge a test piece is taken out and forged. If it happens to be too soft some coke powder is thrown in until the right properties are obtained. Generally speaking, the charge is finished in one and a quarter to two hours, but, if required, steel can without disadvantage be kept in the furnace for ten hours or more.

The final product is especially distinguished by its great strength, equality, and homogeneity. Rails have been made which showed a much higher bending and breaking point than ordinary Bessemer or Thomas rails, and these command in the market from 25s. to 45s. per ton more than ordinary rails owing to their greater durability.

It may be of interest to know that in this country Messrs. Vickers, Sons & Maxim have a 150 kw. Kjellin furnace, and they also built one of the same capacity for the American Electric Furnace Company, which is working upon the Canadian side of the Niagara Falls, and the Gröndal Kjellin Co., Ltd., have a 60-kw. experimental furnace near Battersea. In Germany a number of the Röchling furnaces are being installed and are giving great satisfaction. Messrs. John Brown & Co., Sheffield, and also Messrs. Wm. Jessop have each of them a Frick furnace. In France the Héroult electrode furnace is mainly used.

TESTS ON SOME LARGE CONTINUOUS-CURRENT MACHINES FOR THE WAR DEPARTMENT

BY the courtesy of Siemens Brothers Dynamo Works, Ltd., we are enabled to give particulars of tests made on some interesting machines which they have recently supplied to the War Department. Fig. 3 is a view of two large generators, which are of special interest as being amongst the largest machines yet built with commutating poles. They will be driven by triple expansion vertical type steam engines supplied by Messrs. Yates & Thom. The armatures will be bolted

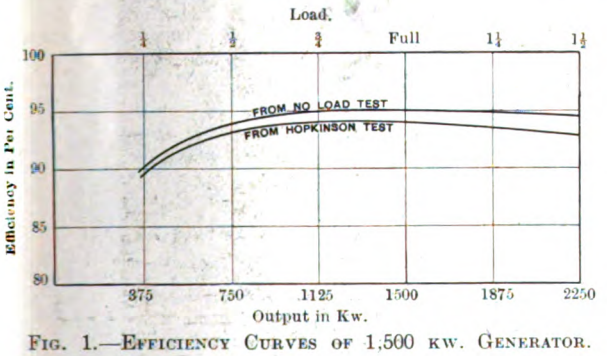

FIG. 1.—EFFICIENCY CURVES OF 1,500 KW. GENERATOR.

directly to the engine flywheels. There are 14 shunt-wound main poles, and an equal number of commutating poles, through the windings of which the whole load current of the machine passes in series. Each machine is designed to give 2,900 amperes continuously at from 500 to 530 volts, or 1,500 kw., when driven at 85 r.p.m. The specified temperature rise of the hottest available part after 12 hours' run on full load is not more than 70° F. (39° C.), and the efficiency not less than 93 per cent. by the Hopkinson test. The specified overload capacity is 25 per cent. for two hours. These specified figures were more than fulfilled on test, the temperatures coming out very low, and the efficiency 94 per cent., that is, 1 per cent. above guarantee.

The machines are constructed as follows:—The yoke is of cast steel, but the main poles are laminated throughout; both the latter and the commutating poles can be removed without

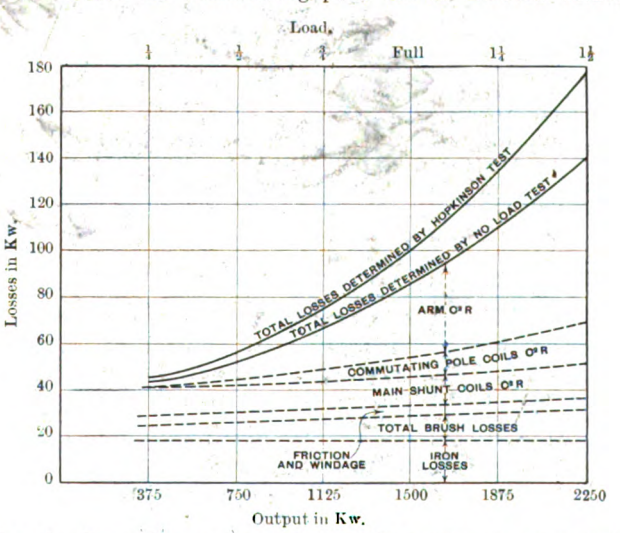

FIG. 2.—TOTAL LOSSES OF 1,500 KW. GENERATOR WITH VARYING LOAD.

dismantling the machine. The armature is of the slotted drum type, and is built up of soft iron laminations, with specially small hysteresis loss. It is mounted on a cast-iron spider, and is well provided with ventilating ducts. Former-wound and interchangable armature coils are employed, and are kept in

Digitized by Google

place in the slots by wooden wedges through the whole of their length, the end connections being secured against displacement by centrifugal force by a special steel binding ring, easily removable. The insulation of the coils consists of layers of mica and presspahn, which are held together with shellac, and moulded while hot over the group of previously taped conductors. A suitable number of equalising rings of large section are provided. The commutator is of hard-drawn high-conductivity copper, and is insulated with mica. Each segment was carefully milled to the correct taper before being built in, and the whole subjected to a heavy pressure before being machined. The brushes are of carbon, the current density at full load being about 30 amperes per square inch.

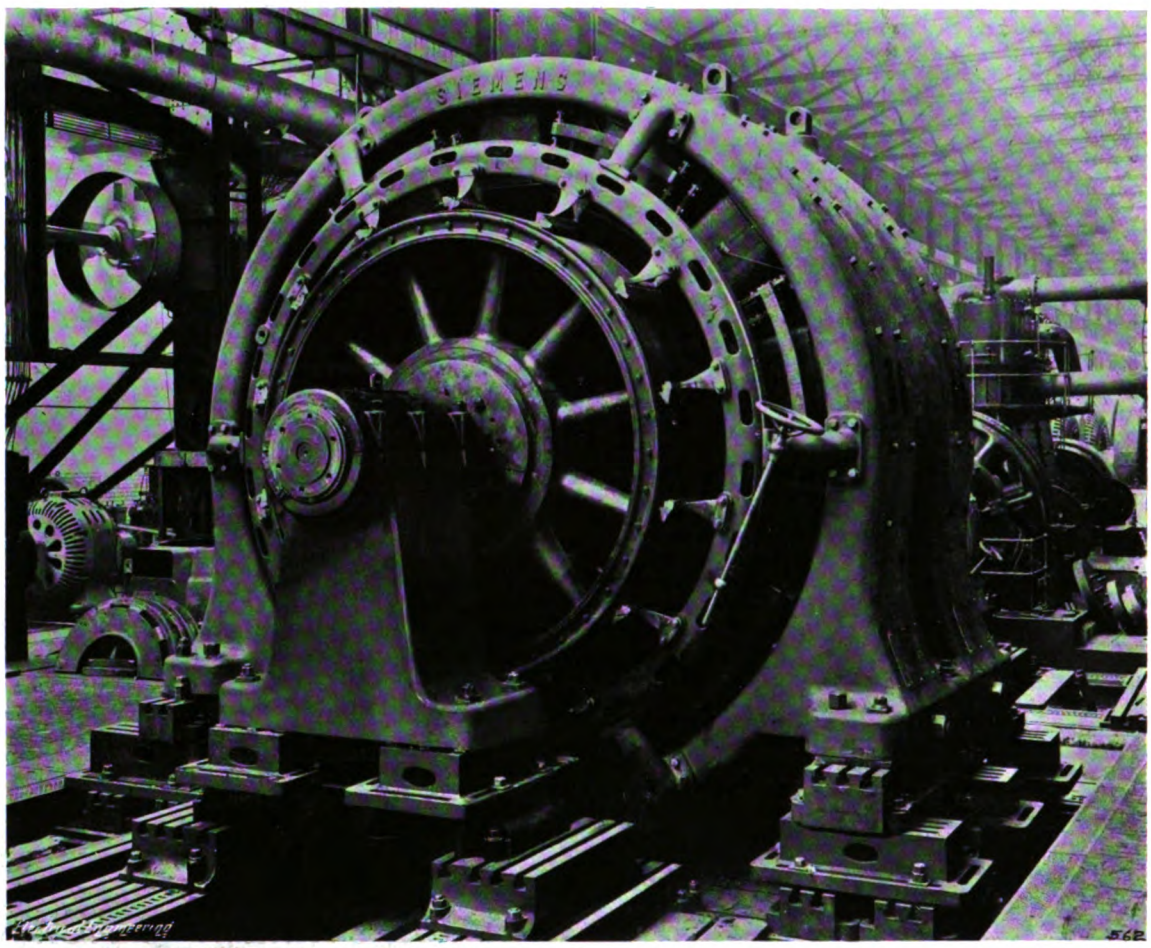

FIG. 3.—1,500 KW., 85 R.P.M., 530-VOLT CONTINUOUS-CURRENT GENERATOR WITH COMMUTATING POLES.

Before leaving the works the machines were subjected to severe tests, and the excellence of their performance may be gathered from the following:—For the 12 hours full-load run at 530 volts, 2,900 amperes, the machines were coupled up together, as shown in Fig. 3, for the parallel Hopkinson test, the losses being supplied electrically, and both fields excited from an external source. The run was made with the gene-

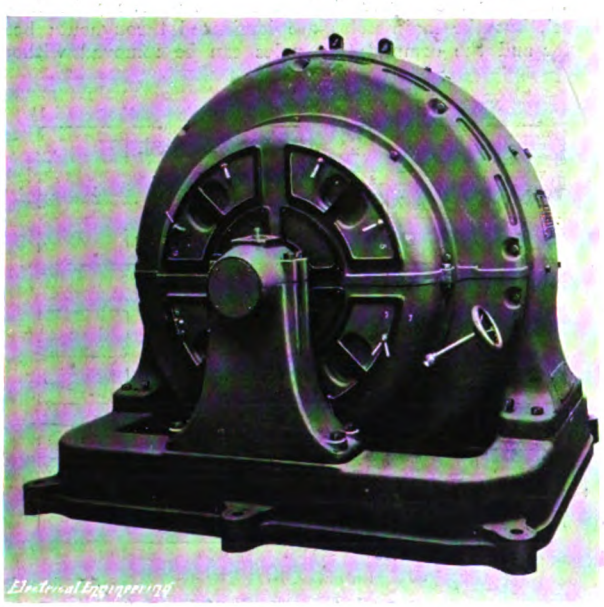

FIG. 4.—100 B.H.P., 100/600 R.P.M. CONTINUOUS-CURRENT MOTOR.

Digitized by Google

rator giving the full rated output of 1,500 kw., corresponding to about 14 per cent. overload on the motor. At the end of 12 hours' continuous run at this output, during which time the commutation was sparkless, the following temperature rises were observed (by thermometer) :—

	Rise in degrees Centigrade above surrounding air.	
	Generator.	Motor.
Arm. core	29° C.	29° C.
Arm. end connections ...	23° C.	24° C.
Commutator	21° C.	18° C.
Shunt coils	31° C.	24·5° C.
Commutating pole coils..	28° C.	32·5° C.

In the efficiency test the machines were coupled up as before, and the following results were obtained :—

	Generator.		Motor.					
Speed. R.p.m.	Amps.	Field. Amps.	Amps.	Field. Amps	Volts common to both.	Amps. supplied externally.	Mean load. Kw.	Efficiency of each machine on mean load.
85·2	740	23·9	842	21·9	532	127	420	90·2%
85·0	1,450	24·8	1,595	20·8	528	172	805	93·4%
85·0	2,250	27·3	2,560	21·9	530	266	1,272	94·0%
85·0	2,970	29·1	3,360	22·8	530	380	1,675	93·8%
85 0	3,700	31·1	4,220	24·0	529	536	2,095	93·3%
85·3	4,500	33·4	5,320	24·9	529	767	2,570	92·2%

It will be noticed that besides being well above the guaranteed figures at full load, the efficiency remained high also at light loads. The maximum motor current of 5,320 amperes corresponds to an overload of 84 per cent., and there was only a trace of sparking. In all the other cases the commutation was sparkless.

A third test of 10 hours' duration was also carried out to determine the temperature rises on overload, the following results being obtained with a generator current of 3,500 amperes and a motor current of 4,000 amperes.

	Temperature rise.	
	Generator.	Motor.
Armature core	36·5° C.	32·5° C.
Commutator	21·5° C.	32·0° C.
Shunt coils	37·0° C.	29·5° C.
Commutating pole coils ...	41·5° C.	57·0° C.

Thus, on an overload of 39 per cent. on the motor for 10 hours, the only parts with a temperature rise higher than that specified for the normal load of 2,900 amperes were the commutating pole windings. The reason for the lower temperature rises on the motor is due to the fact that the cool air was delivered to the motor side of the combination, and the generator had the disadvantage of receiving air which had already passed the motor. In calculating the temperature rise, the mean air temperature was taken, and this, of course, handicapped the generator. The commutation was perfect throughout the test. It is well known that the sum of the no-load losses plus the additional C^2R losses due to the load do not make up the total power lost at full load, but the extent of this discrepancy is not generally recognised, and has led to much doubtful practice in specifying efficiencies. The serious nature of this error is well illustrated in Fig. 2, in which the upper curve represents the total losses as given by the Hopkinson test, and the lower curve the total losses as obtained from a no-load test. In the lower curve of Fig. 2, half the losses supplied from external sources are plotted against the mean load of the coupled machine, as found from the Hopkinson test. The discrepancy in the efficiency as obtained by these two methods is very considerable, as may be gathered from Fig. 1, and the following table :—

Load.	Efficiency by Hopkinson test.	Efficiency by no-load test.	Guaranteed efficiency.
50% overload	93%	94·5%	—
Full load	94%	95%	93%
Three-quarter load ...	94%	94·8%	—
Half-load	93%	93·8%	—
Quarter-load ...	89·5%	90·2%	—

In view of the fact that machines are sometimes required to give their full load current with a very weak field (for instance, for Siemens-Ilgner flywheel converters for colliery winding, where a current considerably in excess of full-load current may be required at practically zero volts), it was decided to test these machines also in this direction. The test was a short-circuit test, and it was observed that about 2 per cent. of the normal shunt current was required to produce full load armature current, and about 3 per cent. for 50 per cent. overload. With the very weak fields thus produced, a current of 4,500 amperes was taken from each machine in turn, and the commutation was quite sparkless, with fixed position of brushes. This current corresponds to an overload of 55 per cent.

Another machine supplied to the War Department, interesting on account of the fact that it is one of the largest, if not the largest motor, yet made with as wide a speed variation as 1 : 6, is shown in Figs. 4 and 5. It is designed to give 100 b.h.p. at a pressure of 500 volts, the speed ranging between 100 and 600 r.p.m. There are six main poles and an equal number of commutating poles. As will be gathered from the illustrations, the motor is of the ventilated type, the openings being covered with gauze. The speed variation is obtained by shunt control, and on test the motor was perfectly stable, and ran absolutely sparkless from no-load to 100 per cent. overload at all speeds. Sparking could not be detected even when the brushes were tilted on to their sparking edge, and a test more severe than this can scarcely be devised. After a five hours' run at full load and 350 r.p.m.—the mean speed of the motor—the temperature rise nowhere exceeded 37° F., and after six hours' full-load run at the highest and lowest speeds, the temperature rises were quite within normal limits. The efficiency of the machine at full load is some 88 per cent. between 200 and 400 r.p.m., but slightly lower at the extreme speeds. In view of the unusual nature and very special design of the motor, this efficiency must be regarded as very satisfactory.

SOME NEW SWITCHBOARD APPARATUS AND METERS

AT the present time practically all voltmeters, wattmeters, controlling apparatus, &c., in high tension systems are operated by potential transformers. Messrs. Ferranti, Ltd., of Holinwood, have given a good deal of attention to the design of this class of apparatus, particularly in the direction of obtaining reliability without undue increase in price. Fig. 1 represents

FIG. 1.—THREE-PHASE, 6,000-VOLT POTENTIAL TRANSFORMER WITH FUSES.

one of the latest products of this nature, of their transformer department, and is reproduced from a photograph of a 6,000-volt, three-phase, 150-volt ampere potential transformer, complete with primary high-tension fuses. This transformer is contained in a sheet-steel tank, oil immersed, and is designed to have a negligible drop, so that it can operate a number of instruments, wattmeters, synchronising gear, and so forth

Another recent product of the same department is the portable ampere-hour meter, illustrated in Fig. 2. The meter itself is of the well-known standard Ferranti type (Hamilton patent).

Digitized by Google

It is contained in a polished mahogany case with leather carrying handle, and flap for protecting the front glass. It is provided with lock and key, and rubber supporting feet, and also with exterior terminals arranged with winged nuts for ease of making the connections. This portable meter should be very useful for testing house-service meters *in situ*, for testing meters about the works, and so forth.

Fig. 5 illustrates another interesting article made by the same works. It is a double reverse current relay for continuous currents, designed by Dr. C. C. Garrard. This relay is intended for protecting the continuous-current side of synchronous motor generator sets. These sets are started from the continuous-current side, with a current equal to, say, 25 per cent. of the normal full load current, the starting current being of course in the reverse direction to the normal. It is necessary for the machine to be protected against taking too large a starting current. With the machine, however, running as a generator, its circuit breaker should be opened if a reversal of very much smaller magnitude than the starting current occurs. The relay, therefore, is provided with two scales. The reverse current at which it operates is given by the sum of the two readings on the scales. Ordinarily, one scale is on zero, and the other scale set to, say, 10 per cent. of the full load current. In starting up from the continuous current side, the setting of the relay is increased by means of the second scale, the resultant setting being given by the sum of the two readings less 100 amperes. It is necessary to subtract this amount of 100 amperes from the sum of the two readings owing to the constant friction, which, of course, is allowed for in the calibration of each individual scale, but naturally comes in twice when the sum of the two scale readings is taken, therefore it has to be subtracted. This relay acts instantaneously on a reversal of current when the machine is running as a generator, or if a too large current is taken when starting up.

FIG. 2.—PORTABLE AMPERE HOUR-METER.

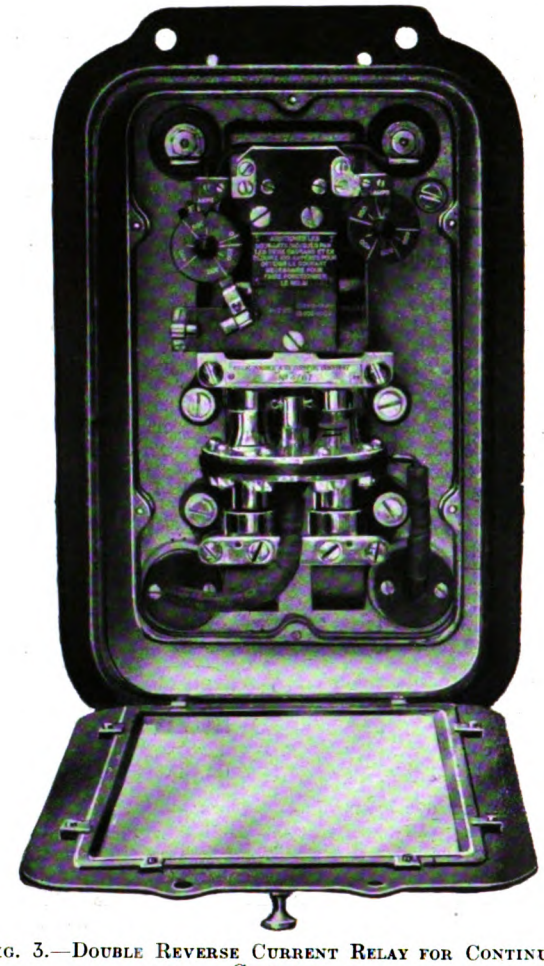

FIG. 3.—DOUBLE REVERSE CURRENT RELAY FOR CONTINUOUS CURRENTS.

Batti-Wallahs' Society.—On the occasion of the annual summer outing, the members of the P. & O. Batti-Wallahs' Society were again entertained at a garden party at Mr. L. M. Waterhouse's riverside residence, "Bindown," Hampton Wick. Mr. Waterhouse was busy during the afternoon taking parties of visitors up the river in his commodious motor launch, and other members were indulged in games and competitions on the lawn, or rowing. The Honorary Secretary, Mr. John F. Avila, informed us that the President has been kind enough to place at the disposal of the committee the sea-going sailing barge *Alde* for a week's cruise between Gravesend and Dover or Yarmouth. It is proposed to sail about Saturday, August 1st, and those members wishing to make one of the party are requested to send in their names immediately. It is suggested to put into convenient ports in the evenings. The cost of catering will be defrayed by those making the trip, and it is estimated that this will work out at about five shillings per head per day. Mention may be made of the fact that gentlemen engaged in the electrical profession are eligible for membership of this society as associates, and it is hoped by the committee that many will come forward under this clause.

The Institution Conversazione.—At the Conversazione of the Institution of Electrical Engineers, held on Thursday last at the Natural History Museum, South Kensington, there was a large gathering of members and friends. The following is a list of the principal members and guests who were present:—Mr. J. Ardron, C.B., Prof. W. E. Ayrton, F.R.S., Mrs. Hertha Ayrton, Sir John Wolfe Barry, K.C.B., Mr. W. G. Cavendish Bentinck, Colonel C. T. Bingham, Sir A. Carmichael Bruce, the Hon. W. M. Bruce, C.B., Prof. H. L. Callendar, F.R.S., Colonel E. T. Clifford, Lord Collins, P.C., Mr. E. Cunliffe-Owen, C.M.G., Dr. E. Divers, F.R.S., General Sir C. W. H. Douglas, K.C.B., Mr. W. Duddell, F.R.S., Mr. A. L. C. Fell, Sir George S. Gibb, Mr. F. Gill, Dr. R. T. Glazebrook, F.R.S., Mr. J. Hunter Gray, Mr. R. Kaye Gray, Mr. H. E. Harrison, Dr. H. S. Hele-Shaw, F.R.S., Capt. the Hon. Fitzroy Hemphill, Sir Walter J. Howell, K.C.B., Sir S. H. C. Hutchinson, Mr. W. Judd, Mr. J. E. Kingsbury, Sir Henry Mance, C.I.E., Sir Hiram Maxim, Mr. W. M. Mordey, Major W. A. J. O'Meara, C.M.G., R.E., Colonel J. C. Oughterson, the Hon. Sir Robert J. Parker, Mr. G. W. Partridge, Mr. W. H. Patchell, Sir Clifton and Lady Robinson, Brig.-General R. M. Ruck, R.E., Dr. Alexander Scott, F.R.S., Mr. J. F. C. Snell, Mr. C. E. Spagnoletti, Mr. C. P. Sparks, Major J. Stewart, R.E., Mr. G. Stoney, Dr. G. Johnstone Stoney, Sir Joseph Swan, F.R.S., Mr. A. A. C. Swinton, Prof. S. P. Thompson, F.R.S., Prof. W. A. Tilden, F.R.S., Mr. A. J. Walter, K.C., the Right Hon. Sir R. Vaughan Williams, P.C., Mr. C. H. Wordingham, and Mr. Israel Zangwill.

THE COLLECTIVE EXHIBIT OF THE ELECTRIC SUPPLY COMPANIES OF LONDON AT THE FRANCO-BRITISH EXHIBITION

A LARGE number of visitors were invited to inspect the collective exhibit which has been arranged in the British Section of the machinery hall at the Franco-British Exhibition by the electric supply companies of London on Friday last. The circumstances which led up to organisation of the co-operative exhibit by the Supply Companies on account of a previous scheme for the representation of the British electrical industry at the exhibition having fallen through need not be recapitulated. The scheme only took definite shape a fortnight or so before the actual opening of the exhibition, so that the time for preparation of the exhibit was short; but both the companies, and more particularly Mr. F. J. Walker, who acted as hon. secretary to the conference as chief official of the London Electric Supply Companies, and the group of firms taking part in the display are to be congratulated on the results of their labours, which have led to the very complete miniature electrical exhibition which it was our pleasure to inspect last Friday. There are in all about 30 exhibitors taking part in the display, and considerations of space do not allow of our attempting to give here more than a general indication of the leading points of interest of some of the principal stands.

The nucleus of the collective display may be said to be the central reception-room, which is not only a comfortable haven of rest and refreshment to the tired visitor, but serves also as an information bureau. Literature relating to electric supply is available, and various views of generating stations adorn the walls. A limited number of exhibits are contained within the reception-room, in addition to the series of stands surrounding it.

THE SUNBEAM LAMP CO., of Gateshead-on-Tyne, have a show-case inside the reception room containing a collection of lamps and accessories of their manufacture. The manufacture of the Sunbeam carbon-filament lamp is demonstrated by a collection of samples of filaments and lamps in various stages of manufacture, but the most interesting objects shown are examples of the new Sunbeam metal lamp. Those in the case are 100-volt lamps, as that part of the case where they are installed had been previously wired for series, but in the reception room they are having fitted some of their 220 volt metal lamps. We have been unable to obtain very full particulars of these lamps, but we are informed that they will burn in any position on alternating or direct current. The case is wired on four circuits with a switch arrangement which lights up sections of the lamps alternatively, giving a very pleasing effect. The Sunbeam Lamp Co. is one of the oldest electric incandescent lamp manufacturers in the kingdom, having been established since 1887, and make every part of their lamps themselves, including the glass work for the bulbs. In addition to the 100-volt metal filament lamps inside the case already mentioned, a number of 220-volt 55-c.p. lamps with an efficiency of 1·35 watts per candle are to be seen hanging from brackets in the reception-room. We believe that we are correct in saying that these are the first British made 220-volt metal filament lamps to be exhibited. The low-volt lamps are running at an efficiency of about 1·2 watts, with a candle-power of 30. The filaments are strong, and likely to bear fair usage in transit, which is fully borne out by the lamps themselves, which arrived at the Exhibition without any special packing. We understand that the company are at present erecting a special factory for the production of these metal lamps, and will be able to meet the demands of the coming season, and are also prepared to guarantee the lamps against infringement, as they are working under license of the Westinghouse patents.

THE BIRMINGHAM GUILD OF HANDICRAFT have an effective show case inside the reception room, in which are shown numerous examples of their artistic electric light fittings. Several new designs of pendants, bracket, table lamps, &c., are exhibited, including a most handsome wall fitting in the centre of the case, in which the lamps are enclosed in an ornamental metal lantern with obscured windows, which has the appearance of being sunk into the wall. The accompanying illustration shows a very graceful form of table standard forming one of the series. Much of the charm and individuality of these fittings is due to the fact that they are almost entirely hand-made by skilled workers thoroughly trained both from the point of view of the artist and the metal worker.

TABLE STANDARD SHOWN BY THE BIRMINGHAM GUILD OF HANDICRAFT.

MESSRS. A. P. LUNDBERG & SON, LTD., have a show case in the reception room containing a large number of examples of their well-known accessories. Among these are switches of the tumbler and other patterns, including a variety of special switches for controlling groups of separate lamps from one or more points combined in some cases with wall plugs and a considerable variety of wall sockets and plugs of every description. A new form of plug which the firm have recently introduced is described and illustrated in another part of this issue.

THE REASON MANUFACTURING CO., of Brighton, exhibit a considerable variety of their manufactures in the reception room. Their well-known electrolytic meters and maximum demand indicators are well represented, in addition to various patterns of house fuse boxes and other accessories. A number of examples of the Reason enclosed arc lamp are shown both in the reception room and outside, and an interesting part of the exhibit is the large show case containing an extensive collection of potentiometers, resistances, and other electrical measuring and testing appliances.

A large electric punkah exhibited by Messrs. BERGTHEIL & YOUNG is fixed to the roof, and assists in keeping the room cool. This apparatus has been designed to imitate the motion produced by the native punkah puller, and is of very ingenious construction. The motor is fixed to the ceiling, and its shaft is vertical. At the bottom end of the shaft is a conical pinion. The punkah itself is carried on a light swinging frame, to which is attached a quadrant of leather or some similar material, at right angles to the punkah, and in such a position that it gears with the motor pinion. It is held against the pinion by a spiral spring, which pulls it to the centre, and as it leaves the pinion it is given a flick, which causes it to swing a considerable distance, and on the return journey to engage with the other side of the pinion.

A number of their specialities are exhibited by the LONDON DECORATIVE METAL WORKS, LTD., including examples of varied designs of switch covers, door furniture, and bell pushes, and in sets to match. The designs cover a large range of styles.

Digitized by Google

Special attention should be drawn to the series of flush switch plates for groups of several switches.

MESSRS. VERITYS, LTD., of Aston, Birmingham, are also among the exhibitors in the reception room, and show electric fans, fittings, and accessories on one of the tables, as well as examples of their arrangement of tubular lamps in reflectors known as "Astonlite" strip, and intended for "concealed" lighting of shop windows, show cases, &c.

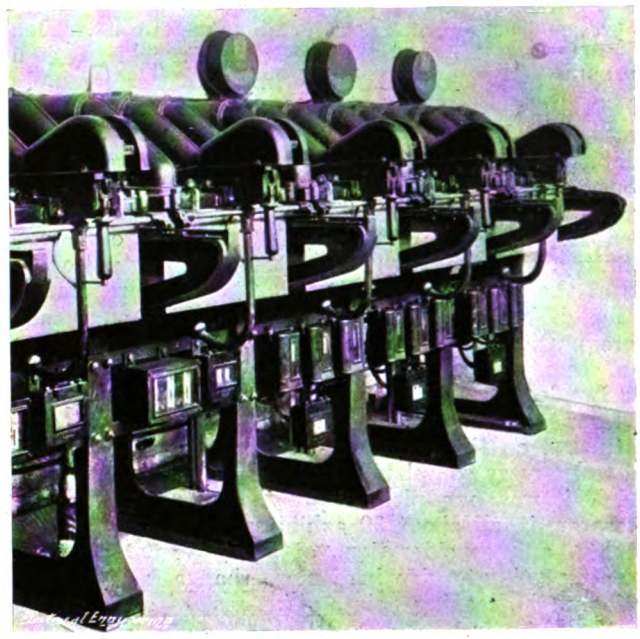
Among other attractions in the reception room is the illuminated fountain of Messrs. KEITH, BLACKMAN & CO., which is a model on a smaller scale of the large fountain combined with ventilating fans, which figured prominently in the centre of the Engineering and Machinery Exhibition at Olympia last year.

Another firm who exhibit artistic fittings is Messrs. GALSWORTHY & Co., of London, who have a small but attractive display in one corner of the reception room.

Two specially interesting stands of the outside group are those of Messrs. A. REYROLLE & Co., of Hebburn-on-Tyne. Attention should be drawn in particular to one of these, where examples of the firm's complete system of ironclad central station and sub-station switchgear are exhibited for the first time. Messrs. Reyrolle have been developing this system for some considerable time, and as a result of the careful attention they have given to the requirement of high tension working have struck out a line embodying many points of originality and interest. As shown in the accompanying illustrations, they have entirely abandoned the use of slate or marble panels and unenclosed conductors, and substituted a substantial construction with all conductors thoroughly encased. In the main the switchgear is built up on the solid system, and is entirely ironclad, the solid nature of the gear rendering it impervious to moisture, while its ironclad construction eliminates all possible danger of accidental contact with it. The high-tension feeder panel exhibited is of the standard type for pressures up to 10,000 volts, fitted with relays and releasing arrangements on the Merz-Price system (see ELECTRICAL ENGINEERING, Vol. III., page 763). The cables enter the ironclad trifurcating box underneath at the back, inside which are fitted the current transformers embedded in the compound with which the box is filled up. The actual oil switch is mounted on a carriage running on steel rails on brackets at the side, so that it can be withdrawn for examination complete with its operating gear, oil tank, &c., by drawing the carriage forward. This action breaks connections to the feeder and the bus bars by the simple withdrawal of knife contacts entirely isolating the switch. Further, on withdrawing the switch carriage, a pair of cast-iron doors

GROUP OF REYROLLE L.T. PANELS.

automatically come forward and close over the face of the chambers in which the live contacts are situated, and the reverse motion automatically folds them up and carries them into a special housing space. The doors can be locked so that access to the live conductors, under any conditions, is impossible. The contacts are purposely made stiff and of large surface, so that some force is necessary to withdraw them. A lever and ratchet arrangement is therefore provided for racking the carriage into and out of position. The handle working



GROUP OF REYROLLE H.T. PANELS.

this terminates in a plug forming part of the tripping circuit, so that it is impossible to draw the carriage forward until the switch is released. It is also impossible to close the switch unless the carriage is locked in place. The oil switch itself has several interesting features. The contacts carried on the fixed portion are mounted on springs, so that they have a certain degree of angular freedom ensuring their proper bedding down upon the wedge-shaped piece driven up between them by the moving part of the switch. They consist of a row—depending in number on the current to be carried—of small separate blocks about half an inch in width, and are arranged to be self-cleaning by having at least half an inch of sliding contact before the travel is completed. Auxiliary renewable sparking tips are fitted to both the fixed and moving portions, and a remarkably ingenious mechanical damping device is provided in the shape of a pair of hinged wings attached to the moving part, which have a sort of "parachute" action, and make the action of the switch gentle by preventing too rapid motion through the oil.

The tripping device is of the simplest construction and reliable in its action, being of the electro-magnet and armature hammer type, and can be supplied suitable for either battery or transformer trip. The automatic break is extremely rapid and certain in action, owing to there being no other moving elements than a lever pivoted on a pin. The handle gear is of the "free handle" type, and when glancing along a line of switches it is easy to see which switches "on" or "off." The switch itself is worked from the handle by a system of wire ropes. In designing this gear the object has been to evolve a line of standard units which may be combined to form panels, to meet all the requirements existing on high-tension networks. Thus, for example, the casings of the bus bars and the intake boxes can be mounted either way up so that the cables may enter from above or below, and the bus bars may be at the top or at the bottom. Again, the operating gear may be attached to the switch carriage as in the gear illustrated, or may be behind the wall. The system fulfils the important requirement of interchangeability, with the advantage that extensions or alterations to similar existing gear can be accomplished at the shortest notice, and without any break in the uniformity.

As already mentioned, the current transformers are contained in the intake chamber. They may be described as being of the ring type. The primary consists of the main cable simply threaded through the bore of a porcelain insulator in the centre of the transformer. When potential transformers are used they are contained within the switch tank immersed in the oil, so that they are completely isolated by withdrawal of the switch carriage.

The low-tension gear is similar in principle and is equally

Digitized by Google

well enclosed and protected; the main points of difference in design are due to the heavier currents carried, and the less stringent requirements as to insulation. Oil break switches are, however, used, even at 440 volts. The accompanying illustrations show the appearance of a complete sub-station equipment, comprising high and low tension gear. An inspection of the apparatus shows not only the complete way in which questions affecting security of working have been studied, but reveals a number of points of detail to which attention has been paid. Amongst these may be mentioned the use of distinctive colours to all wires and connections to avoid possibility of confusion, and the provision of spring washers to every nut, to obviate the effects of vibration. It should be said that this form of gear has been applied already to some 30 or 40 sub-stations in the north of England, where over 200 panels are in use. Examples are also to be found in the Carville Power Station of the Newcastle Electric Supply Co.

In addition to this display of heavy switchgear, Messrs. Reyrolle & Co. have another stand, on which are shown a great variety of starters, resistances, fuses, and switchgear generally. Attention should be drawn particularly to the special resistance with which all the starters are fitted. This is composed of a number of units, in which the resistance material is a special variety of powdered graphite enclosed in an asbestos frame and clamped between metal plates. This resistance has an even more strongly negative temperature coefficient than solid carbon, with the result that even with a starter with only one resistance step an excellent graduation of the starting current is obtainable. In using starters fitted with this resistance all that is necessary in starting up the motor is to bring the lever or drum, as the case may be, to the starting position and to wait there until the motor starts, which it must eventually do as a result of the gradual and automatic increase in current due to the automatic decrease in resistance.

In addition to the various types of lever starters shown, examples are on view of the firm's drum type starter, which combines in one apparatus all the functions of a complete motor panel. Each starter is fitted with an interlocked double-pole switch, which is loose upon the main spindle; consequently, should an overload occur, either in the starting or running positions, the motor is at once isolated from the mains. A press button is provided for stopping, which trips both the drum and the main switch. These starters can also be fitted with a shunt regulator, in which case starting is effected during the first revolution, while the speed regulation is effected during the second by varying the shunt resistance. Other articles exhibited include low-tension fuses of the ventilated type, fitted with a double asbestos lining, which allows a continuous-current of air to circulate through every part of the apparatus and acts as a buffer against the explosive action of the fusing wire, high-tension fuses, wall plugs, fuse boxes, and oil switches. Other exhibits are telephone dividing boxes, large quick-break switches, small fuse boxes, house service fuse boxes, &c., &c.

THE EDISON & SWAN UNITED ELECTRIC LIGHT CO. occupy a prominent corner position on the outer ring of stands, but almost as much interest will centre round the examples of the new Royal Ediswan metal filament lamps, by which part of the lighting of the reception-room is effected and which make their public appearance for the first time. These particular lamps are of the 16-c.p. 50-volt size, arranged two in series on the 100-volt circuit. We are not at present able to give very full particulars as to these lamps beyond stating that they can be run in any position and are equally suitable for continuous- or alternating-current circuits. The company have also some of their white flame arc lamps, using pure carbons, in the reception room. On the stand itself are, of course, examples of incandescent lamps of every form and shape, and samples showing the various stages of manufacture. A large number of artistic fittings are shown, among which we should call particular attention to a group of table lamps and other fittings in Doulton ware, embodying some striking colour effects.

THE "COURT OF HONOUR" AT NIGHT, ILLUMINATED BY ROYAL EDISWAN LAMPS.

In addition to lamps and fittings, the exhibits comprise a variety of switchgear, including a new lever switch with a quick-make as well as a quick-break action. The Ediswan circuit-breaker is also on exhibition, together with the newest branch switch, named the "Phlatta," which is in use in the furnished flat forming part of the collective exhibit and other parts of the exhibition. A large show-case contains a complete range of measuring instruments, from the large central station type to the pocket cell tester, including the useful series of instruments for motor circuits, calibrated direct in horse-power. Examples are also to be seen of small auto-transformers for enabling small candle-power metal filament lamps to be used with high supply voltages. These are specially designed for small no-load loss and have a power factor of about 0·99 at three-quarters and full load. The Edison & Swan Electric Light Co. supplied the whole of the lamps used for the decorative exterior lighting of the buildings in the exhibition, and the fine effect produced is well shown by the photograph of the "Court of Honour" at night, which we are able to reproduce.

THE STEARN ELECTRIC LAMP CO., LTD., of 47 Victoria-street, Westminster, and Kew Gardens have an interesting exhibit of their English-made "Leuconium" metallic filament lamps, specially illustrating the use of these high-efficiency lamps, con-

Digitized by Google

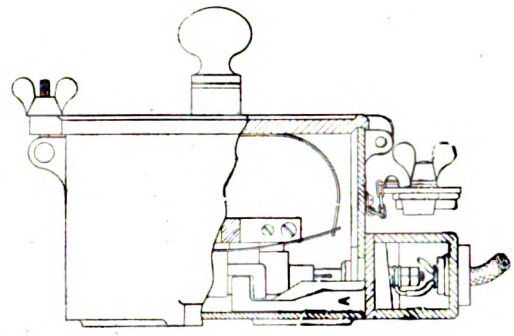
suming as they do only about 1¼ watts per English candle on a 220-volt circuit. The particular lamps shown are what they term their "Nevaout" series lamps, these being all fitted with a special automatic fuse in the cap of the lamp, and a substitutional carbon resistance in the bulb, so that, used in series, the failure of one lamp does not entail the extinguishing of the whole group as in ordinary series lighting, but with this device the circuit is automatically maintained through the carbon resistance until a new lamp is put in place of the broken one. The construction of these lamps was described in some detail in ELECTRICAL ENGINEERING, April 30th, page 651. The appearance of a 100-volt lamp made up of five units in series is shown in the figure.

The exhibit consists of a five-light electrolier, fitted with four lamps of 44 volts, the fifth point being occupied by a double tubular fitting, each tube being 22 volts, the total making the 220 volts used on the circuit. A three-light bracket is also shown, in which each point is for 74 volts, and in this case the two outer lamps are of bulb form, whilst the centre

FIVE-TUBE STEARN SERIES METAL FILAMENT LAMP WITH SUBSTITUTIONAL RESISTANCES.

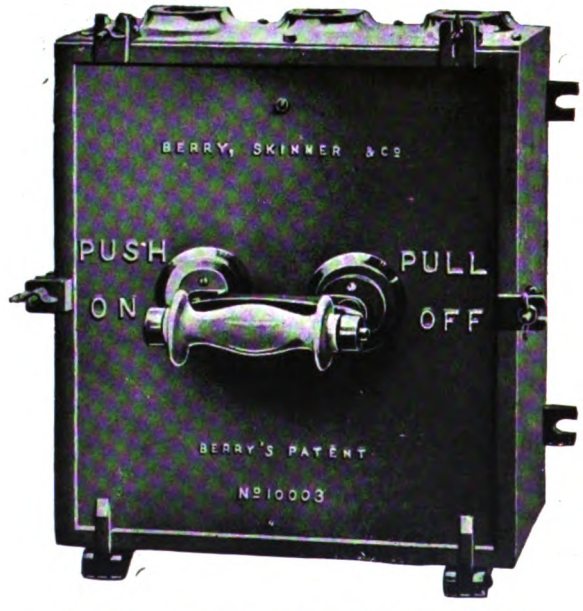
point is a three-tube cluster. Below this are two three-light brackets, with all six points wired in series, and consequently smaller c.p. at each point. There are two small standards illustrating the use of 55-volt lamps, four in series on 220 volts, one being fitted with ordinary bulb form lamps, the other with the special tubular form in clusters of three. This same system is shown by two single-point drop lights used direct on the 220 volts, the one consisting of a four-tube cluster fitting, each unit being 55 volts, and the other of a five-tube cluster fitting, each unit being 44 volts. These demonstrate the system for single points, and it is evident that not only is the loss by breakage of the filament reduced to the cost of one tube instead of a whole lamp, containing probably seven to ten filaments, but whereas with the single-light ordinary bulb form, if a filament breaks, the room is plunged in darkness, by this arrangement of automatic fuse the light is merely reduced by one-fifth in the one case and one-fourth in the other case. The Stearn Electric Lamp Co., Ltd., make a great point of the utility of this device for street lighting, and show a 10-tube fitting, fitted up in an ordinary street gas lantern.

MESSRS. BERRY, SKINNER & Co. exhibit a group of their enclosed switches of the push-on and pull-off type, which are used in very large numbers on the distribution boards throughout the exhibition. The construction of this apparatus is shown in the accompanying illustrations. The moving part of the switch is carried on a plunger terminating in the external knob or handle working through the lid, and a pair of springs are provided which produce a quick break and make effect by a sort of toggle action. The tubular fuses actually form part of the moving switch piece, so that the action of pulling off the switch is simply that of removing the fuses from their clips. They are made accessible for replacement by throwing back the lid, and, of course, the circuit cannot be made until the lid is closed again. A special form combined with a detachable plug for colliery work, in which interlocking arrangements are provided so that the plug cannot be removed or inserted unless the circuit is broken, is also shown. Another exhibit on the same stand is a complete electrically-driven ice-making plant on the carbonic acid system, suitable for country houses, hotels, &c., driven by a one horse-



SECTION OF SWITCH WITH INTERLOCKED PLUG.

power motor, and capable of producing 280 lb. of ice per day. Messrs. Berry, Skinner & Co. have also on exhibition examples of the Beck flame-arc lamp for direct or alternating current. The construction of this lamp is remarkably simple. The feed is entirely by gravity. Each carbon is constructed with a ridge the end of which rests on a copper abutment piece, and as it burns away permits the carbons to feed. The only mechanism is a simple striking device for allowing the carbons to come together at starting, and separating them through the action of a solenoid, which temporarily shifts a guide through which one of the carbons passes. A very high efficiency is claimed for this lamp. A special form of series resistance consisting of a metal wire enclosed in hydrogen can be used in place of the ordinary resistance when it is desired to run them on low-voltage circuits. On account of the temperature coefficient of this form of resistance, an equally good steadying effect can be produced on the



BERRY PATENT PUSH-ON AND PULL-OFF SWITCH.

arc without so great a voltage drop as is produced in the ordinary resistance. By means of this arrangement two lamps can easily be run in series on 100 volts.

Messrs. ELECTROMOTORS, Ltd., of Openshaw, Manchester, have a stand the object of which is to show a few examples of the methods of applying their well-known continuous-current motors to various classes of driving. At the back of the stand is a small motor-generator set, and in front of this are a group of motors fitted with various kinds of reduction gear, including ordinary "back" gear mounted on the motor frame, worm gear, &c. Flexible shaft drills are also shown, and another applica-

Digitized by Google

tion of flexible shaft driving in the shape of an electrically-driven horse-clipper, which is stated to be able to clip a horse in thirty minutes. A small electric winch is exhibited, and electric fans of several patterns are in operation.

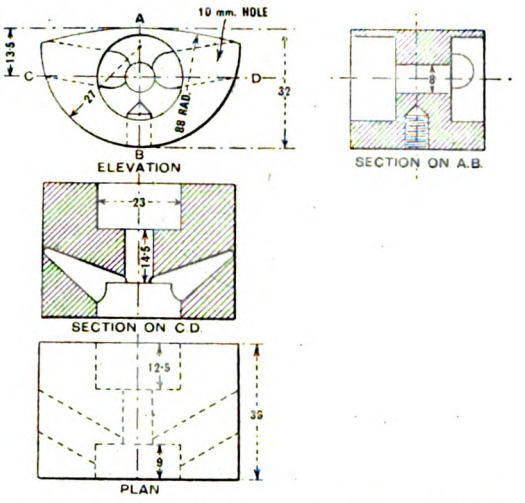
The ADAMS MANUFACTURING Co., of London and Bedford, have a display of a large variety of motor-controlling apparatus. An automatic float switch controlling a pump motor by a solenoid starter is shown in action. Other apparatus includes a lift controller consisting of a rope-operated reversing switch and a self-acting motor-starting rheostat suitable for dinner-lifts and similar work. A 20 h.p. self-acting motor-starting rheostat is also shown in operation actuated by two push-buttons, one for starting and one for stopping. The largest example of this kind of apparatus shown in operation on the stand is a 75 h.p. 500-volt self-acting starter. For this large horse-power the sliding type of contact is not used at all, but, instead, the motor circuit is opened and closed by a solenoid switch, which is fitted with carbon break and powerful magnetic blow-out, and the various steps of starting resistance are cut out in succession by a number of similar solenoid switches, all of which close in their turn, and at the proper interval, with a snap movement, and make circuit by pressing a laminated copper brush against hard-rolled metal surfaces. An interesting piece of apparatus is the Adams "Igranic" printing-press controller, which is designed for controlling large electrically-driven rotary printing presses of the type used for printing the large London daily newspapers. This is capable of regulating the speed of the press through a very wide range, the ratio in some cases being 40 or 50 to 1. All the speeds are obtained by use of only one handle and only one motor, and, moreover, we understand that each step represents a definite and positive speed. With this controller push buttons are supplied, which can be installed in convenient positions round the press, so that the press may be started, stopped, and "inched" from any of these positions. There are also two specimens of "Igranic" printing-press controllers for flat-bed presses. These are entirely ironclad, and are equipped with no-volt and overload automatic release, with magnetic blow-out and long range of speed control by variation of the shunt field. Both are entirely ironclad, and seem about as robust and reliable as the very arduous conditions of work in a printing works requires. Other items of the exhibit include a 30 h.p. 220-volt reversible crane controller of the face-plate type and various examples of ironclad field regulators, their drum or tramway type controllers, motor starters with no-volt and overload release, fan regulators, and many other types. An interesting new type of resistance with wires embedded in glass has been developed by the company.

Messrs. O. C. HAWKES, LTD., have a small stand, on which are displayed a number of examples of their well-known heaters of the convection type, in which they have specialized for some time. The heaters shown exemplify a wide range of styles of decoration. The advantage claimed for this form of heater against the luminous type are the more efficient circulation of the heated air and the consequent rapid rise in the temperature of the room as a whole, and the sterilising effect of bringing the air into more intimate contact with the heated conductor, and therefore to a higher temperature when it is passing through the stove.

The BRITISH THOMSON-HOUSTON Co. have a fine display representing the long series of heating and cooking appliances, which we have noticed in our columns from time to time, but perhaps the most interesting feature of the stand is the appearance of the B.T.-H. tungsten lamp, made at Rugby. We hope to give a full description of this new lamp in our columns at an early date.

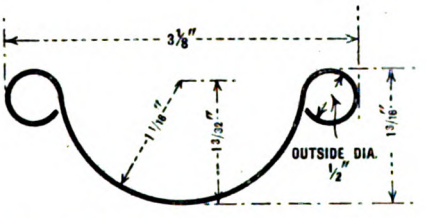
One of the largest stands is that of the DOWSING RADIANT HEAT Co., which is entirely devoted to electro-medical apparatus. Prominent among the exhibits is a bed for radiant heat treatment, in which the rheostat and connections, by which the radiator lamps in reflectors surrounding the bed are controlled, are conveniently mounted on the bed itself, so that the whole apparatus is self-contained. Several patterns of "solarium" or electric light bath-cabinet, for home and hospital use, are shown, including a portable folding form. It is claimed that this form of "bath" is much more healthy than the ordinary Turkish bath, as, although the body is subjected to a high temperature, the patient can breathe cool external air instead of inhaling harmful fumes. Some of these are specially arranged with screens before the lamps for special treatment by coloured light. A form of hydro-electric chair is also shown, in which the extremities of the limbs are immersed in glass vessels, so that current can be conveyed through the body more effectually and under better control than in the ordinary "electric bath," as the whole of the current measured passes through the body. A switchboard at the side is fully equipped with regulating, controlling, and converting apparatus enabling "continuous," "sinusoidal," or "Faradic" applications to be made. On the same stand is a display of Röntgen ray and high-frequency apparatus manufactured by Messrs. Harry W. Cox & Co., including coils with the newest form of mercury jet break, with the break occurring in coal-gas. Some powerful Röntgen-ray tubes are shown provided with special protection for the operators, and various accessories for Röntgen-ray work, including apparatus for localising bullets. Mention should also be made of the examples to be seen on the stand of the forms of luminous radiator with which Mr. Dowsing has been identified since the pioneering days of domestic electrical heating.

On the stand of the LINOLITE Co. are shown examples of lamps and fittings for their well-known "Tubolite" system of lighting by means of rows of tubular incandescent lamps placed end to end in specially designed aluminium reflectors. The two edges of the reflector are rolled up to form a beading on each side, and these carry the two wires. The angle of the reflector is such that the light is distributed over an angle of



PORCELAIN LAMP HOLDER FOR "TUBOLITE" STRIP.

140 degrees. The accompanying illustration shows the latest form of porcelain holder for the ends of the lamps. There are two standard sizes of strip, one for lamps of 12 c.p. each, and a large size for 32 c.p. lamps; the proportions of the



SECTION OF REFLECTOR FOR 32-C.P. "TUBOLITE."

reflector for the larger size are shown below. The various parts composing the equipment are shown in different stages of manufacture.

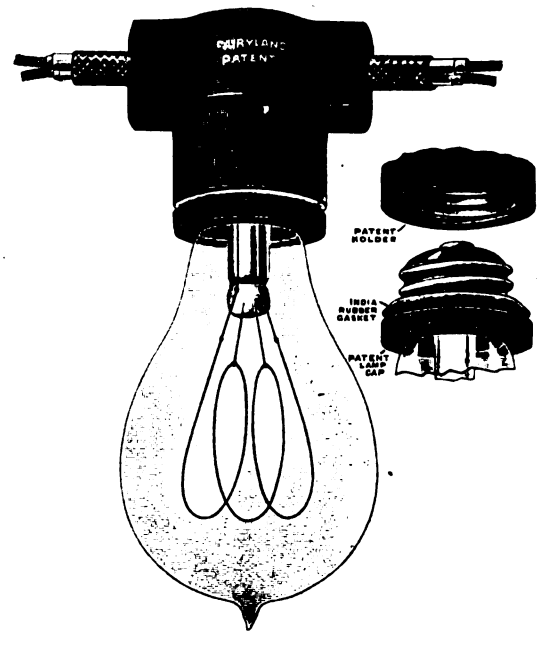
Messrs. R. WAYGOOD & Co. show a complete working model of an electric lift with their patent system of push button control, requiring no attendant.

A good display of arc lamps of various types, including enclosed and open lamps and special lamps for photographic purposes is made on the stand of the WESTMINSTER ENGINEERING Co.

The IMPERIAL LIGHTING Co. have an extensive exhibit exemplifying the applications of electricity to decorative and theatrical lighting and advertising signs, &c. Specimens are on view of several varieties of the firm's well-known "Fairyland Strip," which is in use for decorative exterior lighting throughout the exhibition. The accompanying illustration shows the arrangement of central pin and screw terminals adopted on the lamp caps, and the packing ring by which an absolutely watertight joint is maintained. A form of metal-backed strip is made to meet the requirements of some of the insurance authorities. Another special type is made with four wires running the whole length, so that two circuits can be carried along the whole length, and the lamps wired alternately on

Digitized by Google

each for colour effects, &c. The component parts of the complete fireproof system for stage lighting which the company have developed are shown. All the wiring is asbestos covered and enclosed in metal troughs. In addition to sample lengths of footlights, battens, floats, &c., a special form of stage



DETAILS OF "FAIRYLAND" STRIP.

pocket is shown and also stage arc lamps and lanterns. Various forms of illuminated advertising signs are shown, and moving appliances driven by small electric motors for shop window purposes.

A number of stands are to be found in the further side of the passage way behind the furnished flat which also forms part of the collective exhibit. One of these, containing Messrs. Reyrolle & Co.'s switchgear, has already been referred to. The remainder, generally speaking, exemplify the applications of electrical power for various purposes. Thus we find a flat bed printing press exhibited by the BABCOCK PRINTING PRESS MANUFACTURING CO., equipped for electrical driving, and provided with the Adams Manufacturing Co.'s system of push-button control. There is also a fine display of wood working machinery shown by Messrs. F. W. REYNOLDS & Co. Electric organ blowing can be studied on the stand of the KINETIC-SWANTON CO., and BARLOW'S PATENT LIFT CO. have a working model of a lift for two floors on the ingenious principle amounting to a variable speed gear described in ELECTRICAL ENGINEERING, Vol. II., October 3rd, page 524, in connection with the Engineering and Machinery Exhibition at Olympia.

Perhaps the most attractive part of the collective electrical exhibit to the general public, and more particularly to the prospective consumer, is the complete miniature furnished flat which has been equipped with so much taste by Messrs. Waring & Gillow, and fitted up to demonstrate the various applications of electricity to domestic comfort, cleanliness, and luxury. The visitor enters a tasteful hall, and wanders successively through a series of miniature rooms forming dining-room, drawing-room, bedroom, nursery, and kitchen. All are lighted electrically in suitable style, provided with radiators for heating and fans for cooling, and a thousand and one small electrical accessories for adding to one's domestic comfort, particularly so in the luxurious bedroom, containing electric footwarmers, warming pans, curling-iron heaters, water boilers, &c. Attention should also be drawn to the very effective and reposeful lighting of the drawing-room by concealed lamps below the frieze.

The feature of the house is the kitchen, completely fitted with every variety of cooking appliance by Messrs. RASHLEIGH PHIPPS & Co., and demonstrated by a lady attendant. This complete electrical kitchen is designed to do away entirely with the use of coal fires or gas stoves, the whole of the usual operations connected with cooking, as also knife cleaning, plate cleaning, boot polishing, and ironing, being done electrically. The cooking-table, which replaces the usual kitchen range, consists of a number of circuits, each controlled by two switches, giving three degrees of heat, pilot lamps being arranged to show which circuits are in use, and special arrangements are made to do away with all loose flexible cords. Fuses for the various circuits, together with main switch and cut-outs, are mounted in two recesses above the switchboard, and an ammeter, showing the total amount of current in use at any time, is provided. In addition to the above-mentioned circuits, which are intended for use with frying-pans, saucepans, kettles, &c., there is provided an electrical oven on an entirely new principle (the first of its kind ever constructed), in which, on account of the high temperature obtainable in the new form of electrical element used, roasting and baking are performed with very much less expenditure of current than has hitherto been required. The various regulating switches and pilot lamps in this instance form a part of the oven, rendering it entirely self-contained and suitable for fixing in a kitchen quite apart from the other portion of the cooking-table. On the top of the oven is fitted a cooking hot-plate, a grill, and a toaster, all fitted with the new high-temperature elements as used in the oven. We may mention that this is the first occasion upon which an efficient and practical electrical toaster has been exhibited. A small boiler, fitted with tap, enabling a supply of hot water to be obtained at any moment, completes the outfit. A canopy is fitted over the cooking-table, which, by means of a small Blackman fan, provides for the efficient ventilation of the kitchen, and prevents any smell of cooking penetrating to other portions of the house. The space under the cooking-table is provided with a rack for holding saucepans, &c., when not in use. The utensils shown in the kitchen suitable for use with the above comprise stewpans, saucepans, frying-pans, omelette-pans, kettles, porringers, potato steamers, coffee-makers, hot-plates, steam cookers, brazing-pans, and fish-kettles. A spacious hot cupboard for warming plates and dishes, and keeping food hot, is also fitted, and electric irons of various shapes and sizes are shown in actual operation. Should the necessary space be available, it is intended also to show an electrical plate and dish washer. In connection with the demonstrations of electrical cooking, which will be given throughout the run of the Exhibition, the chief points which will strike the onlooker will be the ease of operation, the absolute cleanliness, the perfect control of heat, giving certainty of results, the entire absence of any obnoxious fumes, which are found so great a drawback to the use of gas stoves for cooking, and the complete freedom from the heat attending cooking by means of a coal range.

In addition to the above apparatus in the kitchen, various other domestic utensils of a similar character are shown in the various rooms as follows: A small hat-iron and a cigar-lighter in the hall; a hot-plate and a kettle in the dining-room; an afternoon tea-kettle and a foot-warmer in the drawing room; a bed-warmer, a bed foot-warmer, and a curling-tong heater, a particularly small and convenient form of hairdryer, a shaving pot, kettle, hot-water jug, and a form of immersion heater used for heating water directly in the washhand basin or jug in the bedroom; the nursery is equipped with a milk-bottle steriliser, a flat-iron, and a kettle, and electric radiators of various designs for warming rooms are also shown, besides electric glue-pots and medical sterilisers.

It should be noted that the kitchen arrangements, having been installed with a special view to giving a thoroughly complete demonstration of electrical cookery in all its branches, are far more extensive and elaborate than would be in any way necessary for a house of the size shown, the accommodation provided being ample for cooking for 30 persons.

The Traffic Problem in New York.—A Consular report states that, in spite of the vastly increased traffic facilities afforded by the new subways and tunnels, the congestion during certain hours is still very bad. The following schemes for further facilitating traffic are being either carried out or are projected:—(1) A municipal subway from City Hall, Manhattan, to the Long Island station at Brooklyn. A portion is already open, and the remainder will be in operation by June 1st. (2) A subway loop connecting the Manhattan terminals of the three bridges, to be finished in two years' time. (3) A subway across Manhattan Bridge to Fort Hamilton, with a two-track branch to Coney Island, the contract for which will be shortly advertised. (4) A route from Battery Park to the Harlem River, passing under the river with two branches, one to Woodlawn, the other to Pelham Park Bay. A cross town line in connection with this scheme is to be made from the Manhattan end of the Manhattan Bridge to the North River, in order to afford traffic facilities to Brooklyn passengers to all of the north and south lines in Manhattan. The estimated cost will be $70,000,000. An extension of the Brooklyn Union Elevated Railroad is also projected. The Hudson and Manhattan Railroad Company is also building its second tunnel under the Hudson River, from Manhattan to Jersey City. The report further states, with reference to the trade of New York, that the value of the electrical machinery exported from New York amounted to £1,149,000 during the year 1907, as against £948,000 for the previous year.

Digitized by Google

THE TELEPHONE AND INFECTION

MR. F. J. ALLAN, Medical Officer of Health for the City of Westminster, has contributed to last week's *Lancet* a rather sensational article headed "The Public Telephone Call Office as a Factor in the Spread of Disease." He says:—

One can scarcely picture a more suitable place for harbouring organisms of all kinds than a dark telephone call-box with its stagnant air and dirty floor, the dust of which is brought in from the street and stirred up and inhaled by each fresh caller. There is, moreover, the risk that organisms of a pathogenic character may be left behind by persons suffering from such complaints as diphtheria, influenza, or consumption.

Dr. Allan goes farther than general statements, however, for he has obtained from Prof. Klein the results of his examination of six "swabs" taken from the mouthpieces of transmitters in public call offices. In five out of the six mouthpieces the results obtained were negative with regard to tubercle, but examination of the sixth revealed the presence of typical tubercle bacilli. This was proved by injecting two guinea pigs with this material; as after killing them and making a *post-mortem* examination 23 and 27 days afterwards respectively, it was found that tubercle bacilli were present.

Dr. Allan concludes:—

As these call-boxes are at present constructed and situated it is difficult to imagine how in the absence of regular disinfection and cleansing they can be anything but breeding grounds for germs. No doubt it is difficult to construct call-boxes which shall be efficiently ventilated and at the same time prevent outside sounds penetrating and conversation being overheard, but it ought not to be an insuperable difficulty. To keep the boxes bacterially clean presents no difficulty. Soap and water are always available, while the thorough spraying of the box and the instrument with an approved disinfectant solution once a day might be carried out with very little labour and at a trifling expense. I am given to understand that by arrangement with the Post Office the whole of the London Stock Exchange telephones, some 40 or 50 in number, are sprayed daily with a disinfectant.

It is hard to imagine that there must not be some cases in which infectious diseases are transmitted by telephone mouthpieces, but it is yet to be regretted that Prof. Klein and Dr. Allan have not pursued their researches further. If ten mouthpieces out of sixty had been found in a dangerous condition, the matter would have called for very prompt and serious remedies, but in this case it is to be noted that only one mouthpiece was found to be infected, although the proportion one in six is, of course, the same. That some method of cleansing and disinfecting, and, above all, of ventilating the call-boxes is desirable, cannot be disputed, but on the other hand there is no need for panic measures.

About three years ago some very similar tests were made by Dr. Collingridge, Medical Officer of the City of London, who selected a dozen mouthpieces from call offices and sent them in a similar manner to Prof. Klein for bacteriological examination. The mouthpieces were washed out, and exactly as in the above case, two guinea pigs were injected, one peritoneally, and the other subcutaneously, and the animals were examined, as in this case, about four weeks after the injection had been made, but no pathological symptoms of tubercle or diphtheria bacilli were found.

As regards subscribers' telephones in ordinary healthy situations which are accessible to fresh air, the daily dusting and wiping of the mouthpieces should be quite a sufficient precaution, as the conditions are entirely different from those obtained in several call offices open to the general public.

The question was raised in the House of Commons on Monday last, when the Postmaster-General was asked whether his attention had been drawn to Dr. Allan's report and as to what arrangements were made to disinfect telephones at the public call offices under the control of the Post Office. In reply, the Postmaster-General said that he had seen the report published in the *Lancet*, but pointed out that five out of the six telephones tested were found non-infectious, and that the sixth was at a railway station in exceptional circumstances. He then referred to the above tests made by Dr. Collingridge, and added that arrangements are made for regularly cleansing and disinfecting the telephones in public call offices, and suggestions for improved methods are under consideration.

ELECTROCHEMISTRY AND ELECTRO-METALLURGY

IN the *Centralblatt für Accumulatoren und Galvanotechnik* of June 20th E. Bäumer suggests the use of iron resistances for regulating the current when charging batteries of accumulators. It is well known how rapidly the electrical resistance of iron increases as the temperature is raised. There is always a difficulty in charging of accumulators, owing to the increase in the resistance of the cells, due to back E.M.F. as the charging proceeds. It therefore becomes necessary to regulate the resistance as the cells become charged up. In order to get over this difficulty and to cause the resistance to act automatically, that is to be gradually thrown out as the back E.M.F. of the cell increases, Bäumer uses iron wire of such a calibre that when the initial current is passed it is kept at a low red heat. As the cell E.M.F. increases the cell resistance increases, consequently the amount of current passing through the wire is less, therefore its temperature falls, and it now becomes a better conductor.

At the last meeting of the American Electrochemical Society Dr. Louis Kahlenberg returned to his attack on the ionic theory. He holds that the hypothesis of Hittorf and that of Arrhenius do not explain sufficiently electrolytic conductivity. Hittorf considered that electrolytes were salts. Arrhenius thinks that all solutions which show abnormal freezing points, boiling points, or abnormal vapour tensions, are electrolytes. But, says Kahlenberg, these generalisations are not correct. For example, an aqueous soap solution which boils practically at the same temperature as pure water is yet an excellent conductor. Consequently, "the vapour tension of solutions . . . and other physical properties so far as we know, do not afford any basis whatsoever of a correct view as to the nature of electrolytes as contrasted with non-electrolyes."

The fundamenal fact which we have to bear in mind is that the best conductors are metals and metallic alloys. Tin is a conductor, but chlorine is not, yet stannous chloride is a conductor, but stannic chloride is an insulator. But there is a difficulty: some substances which contain no metal are electrolytes when in solution, and others are not. Acetic acid is a non-conductor, so is water, but an aqueous solution of acetic acid will conduct the electric current. Dr. Kahlenberg thinks that much more intelligent experimental work must be carried out before we can hope for a real improvement of our theories of the interrelation of electricity and matter.

At the last meeting of the Faraday Society, Ad. Jouve contributed an interesting Paper upon "New Applications of Electrometallurgical Alloys." This Paper dealt mainly with the use of silicon alloys, particularly of ferro-silicon. This substance is manufactured containing percentages of silicon varying from 20 to 75 per cent., the most usual being 20 to 25, 50 to 55, and 70 to 75 per cent. Attention was drawn to the fact well known to analysts, that no methods of analysis for this substance, based upon the use of acids, with the exception of hydrofluoric acid, are employed for ferro-silicons, because ferro-silicon containing more than 20 per cent. of silicon is insoluble in acids. This protective property of silicon is being made use of in producing acid-resisting vessels. Ferro-silicons, however, are not the only substances which possess this property, almost any alloy of a metal with this metalloid will behave in the same way to a greater or less degree, according to the nature of the metal. Calcium silicide is, for example, unaffected by acid, whereas calcium itself acts vigorously upon water. The chief difficulty met with in preparing metallic silicates in the form of vessels is the brittle nature of the alloy; they contract on cooling, often breaking in the mould when hardly solid, and when still at a red heat. In manufacturing the apparatus the first process consists in obtaining a melted metal suitable for pouring into moulds. The most satisfactory method, and the one most generally employed, is to pour directly from the electric furnace into a mould lined with some refractory material. Once the liquid is obtained, metals for corrective purposes are added directly to the metal in the casting ladle, generally with addition of aluminium, which raises the temperature of the bath and increases its fluidity. As showing the resistance of these alloys, which are called "metillures," to acids, the following example is interesting. Nitric acid, even as a vapour, such as is obtained at the exit of a bisulphate retort, or when mixed with nitrous acid, does not affect them at all. A striking example of this is given by a pipe which has been submitted

Digitized by Google

for nearly five years to the daily passage of 660 lbs. of nitric acid vapour at temperatures varying from 150° to 200°, without its loss in weight exceeding a few decigrammes in a total weight of about twenty kilogrammes. This loss occurred quite at the beginning of the period, and was probably due to a few impurities remaining on the inner surface of the pipe after fusion. Sulphuric acid has still less effect; the acids of strength from 20 to 25 per cent., known as *petites eaux*, may be concentrated in vessels of this kind by direct heating and continuous evaporation. Hydrochloric acid is analogous in its action, and use has been made of the pipes of the above material for carrying and condensing its gases. Acetic acid and the mixture produced by treating calcium acetate with sulphuric acid, are without effect on "metillures," even in the presence of air. The apparatus constructed up to the present time is extremely varied, both in form and dimensions, ranging from evaporating dishes, troughs, right-angled bends, elbows, worms, ventilators, &c., varying in weight from about 20 lb., and having a diameter of 1 ft., to those weighing over 1 ton, and measuring 7 ft. across, as well as pipes with a diameter of 8 ft., and weighing about ¾ of a ton. The points in connection with these new substances is that it is due to the great advance which has recently been made in electric furnace methods, that the possibility of preparing these alloys has been arrived at. Platinum, the most stable of our industrial metals, is becoming scarcer, whilst its price is increasing, and this makes its employment very expensive, consequently the advent of these new acid-proof materials should be of very great commercial importance.

ELECTRICAL SCIENCE

British and American

Secondary Radiation from β-Rays.—When the β-rays of radium are caused to fall on a plate of any substance, other rays known as "secondary" can be detected spreading out from the plate. That the β-rays are not merely reflected is seen from the experimental fact that the secondary rays possess qualities dependent upon the atomic weight of the substance of the plate if that substance be elementary, and upon the atomic weights of the elementary constituents of the plate if the plate consist of a chemical compound. Very many measurements have been made on these secondary rays from plates of different substances, and practically all under the same condition as regards the angle of incidence of the original rays on the plate, or as regards the angle of emergence of the secondary rays. In a Paper in the June *Proceedings* of the Royal Society, J. A. McClelland describes measurements of the intensity of the secondary radiation emitted at different angles from the plate for various angles of incidence of the β-rays. The radium was placed at the closed end of a thick lead tube, which was set horizontally with its open end pointing inwards along the radius of a circle round which it could be moved. At the centre of the circle the plate was placed with its plane vertical, and so that it could be rotated about its vertical centre-line. A fixed ionisation chamber, consisting of a metal tube with an insulated central wire, was set at a little distance from the plate, so that secondary radiation from the plate could enter the chamber by passing through a single sheet of tin-foil covering its end. By moving the plate relative to the radium any desired angle of incidence could be settled upon, and by then moving plate and radium together the secondary ray emission at various angles from the plate could be examined. The author obtains in this way a number of curves connecting secondary radiation and angle of emission from plate, for a series of values of the angle of incidence of the β-rays. For normal incidence the secondary radiation curve is almost a cosine curve; a result which follows from the theoretical consideration that the radiation from an element of volume at a depth in the plate traverses a thickness inversely proportional to the cosine of the angle of the rays from the normal. The secondary curves for other angles than perpendicular incidence have a maximum ordinate at a place suggesting direct reflection of β-rays. Consequently, as a rough method of analysing these curves, the author takes the difference between the ordinates for equal angles on opposite sides of the normal, as representing the merely reflected portion of the radiation. By measurements of the absorption coefficients of radiation coming off the plate at different angles, the author shows this mode of analysis to be justified, and thus reaches the important conclusion that, whatever the material of the plate, there is a practically invariable amount of radiation reflected at any particular angle. It follows from this that when the true secondary radiation from different substances, corrected for reflected rays, is considered, it is found to possess an intensity directly dependent on the atomic weight of the metal of the plate.

Royal Society Conversazione.—The second annual conversazione given by the Royal Society was held on Monday last in the rooms of the Society at Burlington House. Most of the exhibits were the same as those shown at the former conversazione in May, and described in ELECTRICAL ENGINEERING, Vol. III., p. 787. Of those on view for the first time, the following may be mentioned: A demonstration by Dr. J. A. Fleming, illustrating the transmission of signals by electromagnetic induction between oscillatory circuits; and a combined Kelvin siphon recorder and cable relay, shown by Dr. Alexander Muirhead, in which the silk fibre of the siphon recorder is replaced by a fine gold wire.

Continental

Sensitiveness of Detectors.—The usual way of discovering improvements in the sensitiveness of detectors is to look for an increase of loudness in the telephone. Such an increase involves an effort of memory, and implies a considerable liability to error. P. Jégou has therefore devised a more reliable null method, which he describes in the *Comptes Rendus* for June 15th. The usual telephone transformer is split up into its two components. The secondary coil is placed in circuit with the electrolytic or other detector to be studied, and the primary, to which the telephones are attached, moves along a scale in close proximity to the secondary. The necessary E.M.F. is taken off a potentiometer, and the current is sent through the detector and secondary coil. The primary is displaced along the scale until the sound becomes inaudible. In testing the sensitiveness of an electrolytic detector at various temperatures, the author found that at a temperature of 12° C. a displacement of 30 mm. sufficed for extinguishing the sound, whereas at 60°, the temperature of maximum sensitiveness, a displacement of 56 mm. was required.

Photoelectric Canal Rays.—H. Dember claims, in No. 7 of the *Annalen der Physik*, to have proved that ultra-violet light, falling upon a fresh zinc surface, does not merely liberate electrons, but also positive particles. The method adopted recalls Goldstein's expedient with the perforated cathode, which enabled him to discover the canal rays. The zinc plate is freshly polished, perforated, and mounted just outside a Faraday ice-pail containing a plate of old copper connecting with an electrometer. On the other side of the zinc plate is a loop of wire serving as an anode, and earthed through a galvanometer. The zinc plate is charged to a negative potential by means of a high-voltage accumulator. The whole apparatus is enclosed in glass casings, with a quartz window to admit the ultra-violet light. Then the electrometer always indicates a small positive charge, while the galvanometer simultaneously shows an electron current. The positive or canal-ray charge gives rise to a current not exceeding 4×10^{-11} ampere, which does not appear to be much above the limit of sensibility.

Microphone Records.—A study of some importance to telephone transmission is contributed by Devaux-Charbonnel to the *Comptes Rendus* for June 15th. An oscillograph was put in circuit with a microphone and a battery, and the curves traced by it were enlarged by projection. The French vowel sounds were chiefly studied. The vowel "ah" was found to consist of the first, second, fourth, and sixth harmonics, with amplitudes 1·0, 1·7, 3·0, and 4·8 respectively, and phase displacements of 0°, 90°, 90°, and −90° respectively. "Oh" consists of the 1st, 3rd, and 5th harmonics; "eh" of the 1st, 2nd, and 12th; French "u" of the 1st, 2nd, and 9th; and English "ee" of the 1st, 2nd, and 13th, with amplitudes in the last case of 1·0, 4·2, and 2·8, and phase displacements of 0°, 0°, and 90° respectively. The 12th and 13th harmonics in the above list appear to be damped. If a number of vowels are pronounced in succession, each vowel takes about five vibrations to attain its complete curve, and another five on terminating. Since one cannot easily pronounce more than ten syllables per second, each vowel has about ten clear vibrations to itself. These must be ensured before we can obtain clear transmission, and experience has shown the importance of clear vowels for the intelligibility of the message.

The Electrical Imports of Japan.—According to a recent Consular report relating to the trade of Japan, the value of the electrical machinery imported during the year 1907 was £259,500, as against £194,400 for the year 1906. The value of the insulated wire imported was £251,400 during 1907, as against £116,600 for the year 1906. Electric cars to the value of £57,000 were also imported, the corresponding figure for last year being £31,200.

Electrical Engineers in the Territorial Army.—The establishment of an Electric Light Corps in the county of Devon is being commenced. According to the *Western Morning News*, the Devon County Association took over the Mutley Barracks, Plymouth, as the headquarters of the Electric Light Corps, which is to be incorporated in the Devon Royal Engineers, under the Territorial Army scheme. It is proposed that the men shall receive their training at the forts around Plymouth, and their annual camp training will also take place at the forts. A complete company will consist of 230 non-commissioned officers and men.

Settlement of Buildings due to Underground Railways.—According to the *Morning Post*, a statement was made at the Bow Street Police Court, in connection with the failure of the owners of Holy Trinity Church, Kingsway, to make certain repairs to the ceiling, that the unsafe state of the structure was due to the settlement of the building consequent upon the construction of the London County Council's underground tramway and the tunnel of the Great Northern, Piccadilly, and Prompton Railway. Damages are claimed against both the County Council and the railway company.

THE RADIO-TELEGRAPHIC CONVENTION

THE "Radio-telegraphic Convention," by which name the Convention between the European and other first-class Powers to regulate wireless telegraph traffic is known, came into force yesterday.

One of the main objects of the Convention is to ensure intercommunication between coast stations and ship stations without regard to the particular system of radio-telegraphy adopted by these stations. Particular stations can be exempted from this obligation, however. The service conditions drafted at Berlin provided for the use of standard wave lengths of 300 and 600 metres at all stations open for public service, the former being regarded as the normal for ship stations. For long distance stations, or stations used for other than public correspondence, wave lengths above 600 but not exceeding 1,600 metres may be used.

The Convention consists of twenty articles relating generally to the enforcement of the terms agreed, and the regulation of wireless telegraphic traffic, and there are also 42 service regulations. An important feature is the exemption of naval wireless stations from the terms of the Convention, with the exception of Articles 8 and 9, which lay down that stations are to be worked so as not to interfere with others, and that calls of distress from ships are to have absolute priority.

According to Article 22, the Convention is to remain in force for an indefinite period, or until the expiration of a year from the date of its denunciation. Denunciation only takes effect as regards the Government in whose name it is made, the Convention remaining in force as regards the other contracting parties.

The countries that have signified their intention of adhering to the terms of the Convention are the Argentine Republic, Austria, Belgium, Brazil, Bulgaria, Chili, Denmark, France, Germany, Great Britain, Greece, Hungary, Japan, Mexico, Monaco, the Netherlands, Norway, Persia, Portugal, Roumania, Russia, Spain, Sweden, Turkey, the United States of America, and Uruguay. The Italian delegate at Berlin in 1906 signed the Convention under the reservation that Italy could only ratify at the expiration of its contracts with Mr. Marconi and his company, or at an earlier date if the Italian Government is able to arrange accordingly by negotiations with the Marconi Company. The adhesion to the Convention of a Government by having colonies, possessions, or protectorates, does not imply the adhesion of these in the absence of a declaration of a Government to that effect. Although all the countries mentioned above have not yet actually ratified the Convention, this is only a question of procedure, and there is no reason to believe that any country has receded from the position taken up in 1906. So far as Great Britain is concerned, His Majesty's Government has ratified the Convention on its own behalf and on behalf of all the Colonies, including India, with the exception of Newfoundland and the Orange River Colony. Mention may also be made of the changed attitude of Marconi's Wireless Telegraph Co., since the Convention was under consideration of the House of Commons Committee last year. The company is now agreed with the British Government, although previously it was antagonistic to the views of the British delegates.

LOCAL NOTES

ABERDEEN: *Supply to Tramway Company.*—The Electricity Committee has again had under consideration the question of the renewal of the agreement with the Aberdeen Suburban Tramways Co. for the supply of electricity, and it has been resolved to ask the Directors of the company to confer with the committee, and meantime to state what objections they have to the terms of the present agreement.

Underground Telephone Wires.—The Postmaster-General has complained of the restrictions imposed in connection with the excavations for the underground telephone wires. The department has been informed that the contractors are prepared to finish very shortly now.

ACCRINGTON: *Tramways Accounts.*—The Tramways Committee have considered a report showing the net profit on the Corporation's electric tramways undertaking for the year ending March 31st to be £1,145. On the electricity undertaking the net profit for the year was £604.

ACTON: *Electrical Exhibition.*—The accounts in connection with the Electrical Exhibition held in January last, under the auspices of the electric lighting department, show a surplus of 18s. 7d.

New Electrical Machinery.—In reply to a question at the last Council meeting, Mr. J. M. Blair, the Electrical Engineer, stated that the motor generators which had been ordered to run direct at 10,000 volts had failed when delivered, and had been rewound by the makers to run at 1,000 volts. The contract price was £2,540 for the 10,000 volts machine, but they were not valued so highly at the lower pressure. To make up the difference and to make them suitable for the different conditions, the contractors had supplied four transformers valued at £550, free of cost. The working results had since justified the acceptance of the machinery.

AMBLE: *Electric Lighting.*—At the monthly meeting of the Urban District Council last week, the question of public lighting was discussed at length, and an offer from the local gas company was considered. Notice was given, however, by one of the councillors that at the August meeting he will bring up a scheme for the supply of electricity.

AUSTRALIA: *Prahran (Victoria).*—The local Electric Lighting and Traction Co. have approached the City Council with a view to making use of steam generated at the Council's refuse destructor works for the generation of electricity. An offer of the Electric Lighting Co., to pay the Council one halfpenny per unit for electricity generated by the surplus steam at the destructor, has been accepted upon a seven years' contract, subject to six months' notice on either side at the end of that time.

BARKING: *Proposed Transfer of Electricity Works.*—At the last meeting of the Urban District Council the Clerk reported that the amended terms for the transfer of the Council's electricity undertaking to the promoters of the London & District Electricity Supply Bill had been duly communicated to the engineers of the scheme, who had replied that the same would be considered after the Bill had passed through the Parliamentary Committee.

BELFAST: *Tramways.*—A special meeting of the Corporation was held on Friday last for the purpose of considering a report from a deputation which had recently visited a number of English cities to make inquiries as to the stages and fares in operation on their tramway systems. The report virtually showed that the existing penny stages in Belfast are excessive, and that they should not under any circumstances exceed two miles. The report also advised the introduction of a halfpenny half-mile fare. After some discussion the report was adopted. The halfpenny fare has been strongly advocated since the tramway was opened.

BERWICK: *Overhead Wires.*—The local Electric Supply Company have applied for powers to erect overhead wires in connection with supply to some factories. The lines will run on private property, and in order to get the consent of the Board of Trade, formal sanction of the local authority is necessary. A report is to be presented at the next meeting.

BIRMINGHAM: *Tramway Inspection.*—On Wednesday last week, by the invitation of Mr. H. Barrow, Chairman of the Tramways Committee, and the Lord Mayor, members of the Tramways Committee and other members of the City Council, in addition to representatives from Aston, Erdington and Handsworth, and King's Norton, made a tour of inspection of the chief depôts and works of the tramway undertaking. During the speeches at a tea which was given at the close of the tour, the Chairman of the Tramways Committee, referring to the running of first class cars, an experiment which is being carried on in Liverpool, said he regarded this as an undemocratic notion, and it would be interesting to see what happened with regard to the Liverpool experiment. It had been urged upon the Birmingham Committee that they should also try this plan, but he thought it would be preferable to have some cars like they had in Paris, in which a man could have his breakfast on his way to town.

BLACKROCK (IRELAND): *Central Ireland Power Bill.*—At a special meeting of the Council last week a resolution was adopted deciding not to lodge a petition against the Central Ireland Electrical Power Bill, provided that the clause for the installation of electric light within two years in the town be

Digitized by Google

included on the terms agreed upon, but in the event of any change in the Bill, as now printed, by the Committee of the House of Lords, the necessary steps be taken to have the clause affecting Blackrock restored to the Bill when in the House of Commons, without expense to the Council.

BRADFORD: *Tramway Accounts.*—The report and balance sheet for the year ended March 31st, 1908, shows a total revenue from all sources of £243,148, an increase of £5,637 over the previous year. The receipts per car mile amounted to 10·591d., against 10·732d. for 1906-7. The number of passengers carried was 47,839,569, an increase of 1,110,592. The total expenditure, including interest and sinking fund, was £167,994, leaving a gross profit of £75,154, against £72,524 for the previous year. The traffic expenses were 2·312d. per car mile, against 2·891d. Although the assessment reduced the amount to be paid in rates by £400, the General Manager reports that he still considers the assessment an unfair one. The accident claims increased by £650, in consequence of the Church Bank disaster in July last year. The amount paid in compensation in respect of this accident was about £2,000. The repairs and maintenance were 1·479d. per car mile, against 1·457d. last year, an increase of about £300, largely accounted for by extra cost of maintenance and electrical equipment of the lines. The Tramway Manager calls attention to this matter in his report, which he says needs the serious consideration of the Committee. A gratifying feature of the repairs account was the decrease of nearly £800, caused through the use of improved methods at the car works. The whole of the surplus of £17,238 has been carried to the reserve and renewals account, which now stands at £52,229. In a comparison between the Bradford system and those of other towns of the United Kingdom, the manager points out that the cost of electric current is a great disadvantage. If they could obtain electricity as cheaply as in Leeds or Sheffield, the power account would be about £15,000 less, and the net profit would consequently have been increased to £52,238.

BURY: *Municipal Tramways Association.*—The Managers' section of the Municipal Tramways Association will hold a meeting in Bury on July 10th, when they will be entertained by the Tramways Committee.

Electric Lighting Tariffs.—The following reduction in the electric lighting tariffs have been approved by the Corporation; private lighting and short-hour users, from 4d. to 3¾d. per unit; shops, 3½ to 5¼d. per unit; hotels, public houses, clubs, and other long hour users, 3d. to 2¾d. per unit; for power purposes the initial charge of 2d. per unit for 1,000 units per quarter is reduced to 1¾d. per unit, whilst the charge of 1d. for the next 1,500 units per quarter remains unaltered. All additional consumption will be at the rate of ¾d., instead of 7/10d. as hitherto. For public lighting a reduction of 10s. per lamp per annum is to be made, and the charge to the Tramways Committee is reduced from 1·05d. to 1d. per unit.

CARDIFF: *Tramwaymen's Grievances.*—The Tramways Committee has again discussed the question of the formation of a conciliation board to deal with disputes and questions of hours, labour, and wages between the tramwaymen and the manager and committee. A deputation from the tramway employees has asked that the recent decision not to consent to the establishment of such a board should be rescinded. It has been ruled that the committee cannot further discuss the matter, although the Council has rescinded the resolution in question.

Workmen's Cars.—There has been some discussion recently as to the liability of the Tramways Committee, under their Acts of Parliament, to run certain workmen's cars. On the advice of the Tramway Manager, some workmen's cars have been discontinued, and a complaint has been lodged, presumably by a ratepayer, with the Board of Trade. In reply to a communication from the latter, Mr. Arthur Ellis, the Manager, and the Town Clerk, have prepared a report which has been forwarded to that department.

Tramway and Lighting Accounts.—Two reports have been prepared by the Cardiff City Treasurer dealing with the accounts of the electric lighting and tramways undertakings. From these it is seen that there is a deficiency of £5,714, owing to the fact that the net profit for the year which has been appropriated for depreciation fund amounted to £8,807, whereas the amount to be set aside for depreciation, as already approved by the City Council, is £14,522 per annum. Similarly, with regard to electric lighting accounts, there is a deficiency of £3,338, which is arrived at by adding £911, the revenue deficiency for the year, to the sum of £2,823, which it has been resolved should be set aside each year for depreciation. The reports in question have not yet come before the Council.

CHELTENHAM: *Alleged Slander.*—The Electrical Engineer to the Cheltenham Corporation, Mr. W. J. Bache, brought an action at the Gloucester Assizes last week against a member of the Town Council, Mr. T. R. Jones, for alleged slander. The alleged slander was contained in a speech by the Councillor, in which he referred to the cutting down of the wages of the workmen at the electricity works. The plaintiff considered the defendant meant by these words that he had been improperly using his position as Electrical Engineer to the Corporation, and had been cutting down the wages of the workmen below what was necessary for their reasonable maintenance so that he might effect economies at the works, and thereby induce the Town Council to give him an increase of salary. For the defence it was stated that the defendant had no malice against Mr. Bache, and did not wish to make any reflection upon him; the speech complained of was an attack upon the Committee, and not upon the official. The jury found for the defendant.

COATBRIDGE: *Electric Lighting.*—The Town Clerk has been instructed to write to certain consulting electrical engineers in Glasgow to inquire if they would be willing to act as electrical inspector, and upon what terms, under the Company's Electric Supply Order, 1890.

DUBLIN: *Quay Tramways.*—The Dublin United Tramways Co. has asked the Dublin Port and Docks Board to permit a tramway to be laid along the south quay for the purpose of conveying coal, &c. The matter has been referred to the engineer for report.

DUMBARTON: *Tramway Extensions.*—On Thursday the tramway lines from Dalmuir to Balloch were opened for traffic after Col. Von Donop had inspected the lines on behalf of the Board of Trade.

DUNDEE: *Competition by Power Co.*—It is stated that the company, with its headquarters in the west of Scotland, has issued a circular to power-users intimating its readiness to supply electricity in Dundee. The circular stated that the company is in possession of the necessary powers for laying wires along the railway tracks, and that working agreements with the railway company have been arrived at. It is intended that three-phase high-tension current shall be generated at some suitable spot in the west of Scotland. The Electricity Committee, which has some doubt as to the powers in question, have decided to further consider it at the next meeting of the Electricity Committee, and it is also mentioned that the subject is one which will engage attention at the Nottingham Convention of the Incorporated Municipal Electrical Association.

ERITH: *Electricity Undertaking Income Tax Assessment.*—The Clerk has been in correspondence with the Surveyor of Taxes and the Clerk to the Income Tax Commissioners with reference to the proposed assessment of the electricity undertaking, and as a result no income tax will be payable in respect of the year 1907.

EXETER: *Electric Lighting Accounts.*—After deducting interest and sinking fund, the net balance is £2,604, the largest obtained in any year since the Council acquired the undertaking from the company. Out of this the Electric Lighting Committee propose to liquidate a charge of £637 upon cables for connecting street lamps, &c., as it is in the nature of capital expenditure. It had originally been intended to spread the repayment of this sum over three years. The coal costs, despite the higher price, have been less than in the preceding year.

GLASGOW: *Tramways.*—The Tramways Committee have expressed their regret that the Clyde Bank Town Council has not consented to a physical junction between the lines of the Dumbarton Borough & County Tramways Co. and the Corporation Tramways at Dalmuir, as they are of opinion that it would have been to the public advantage.

GREECE: *Electric Tramways.*—It is expected that some of the most important lines in Piræus will be ready shortly. Fifteen coaches have already been received, and some 90 more are expected very soon, these having been ordered in Milan. The Tramways Company, although practically of Belgian origin, is now styled Societe Hellenique de Tramways d'Athene-Piree et Environs, and has head offices in Athens. The capital of the company is £714,286, divided into 200,000 shares of £3 10s. 6d.

ILFORD: *Electricity Accounts.*—Commenting upon the Accountant's abstract of accounts relating to the electricity undertaking, at the meeting of the Urban District Council, Councillor Philpot drew especial attention to the fact that the reserve fund now stood at £6,483. During the year £5,577 additional capital had been spent, making a total expended on the undertaking of £157,271. The business of the undertaking was still increasing, and there was a gross profit on the year's work of £9,670. However, instalments of interest and principal, interest on mortgage debt, and a repayment of £557 to the tramway department on account of machinery used for generation of electricity had taken an expenditure of £10,045, so that there was a deficit of £375. Councillor Philpot mentioned that the price of coal advanced during the year, and the undertaking had to pay more, and for twelve months the charge of 3½d. per unit to the ordinary consumer, instead of 4d., had been in force. The price for public lighting had been reduced to £3 15s. per lamp, and in nearly 400 cases the department had changed the 30 c.p. single lamp to a 50 c.p. double lamp, so that the lighting of the urban part of the district had been considerably improved.

ITALY: *Wireless Telegraphy.*—According to a British Consular report, a wireless telegraph station is to be set up at Palermo for communication with Naples and Cagliaria in Sardinia. A wireless station is already in operation between Messina and Calabria for railway purposes, and a Marconi station at Cozzo Spadaro in the Province of Syracuse is attached to the naval station there.

Telephones.—During the second half of 1907 the public telephone system of Italy passed into the possession of the State, which promised cheaper telephones and a better service—not yet realised. The direct service between Rome and Palermo is still very unsatisfactory. A thicker wire is to replace the present

Digitized by Google

one. At the present moment the following towns in Sicily are in telephonic communication with Palermo and each other :—Acireale, Alcamo, Caltagirone, Caltanisetta, Castellamare, Golfo, Castrogiovanni, Catania, Cefalu, Girgenti, Leonforte, Messina, Mistretta; Nicosia, Noto, Porto Empedocle, Sciacca, Syracuse, Termini, Terranova, and Trapani.

JAPAN: *Electric Power Supply.*—A British Consular report makes some reference to the works of the Oshima Hydro Electric Power Co., at Hakodate, which are now under construction. The works are situated about 20 miles from Hakodate, near the outlet of Lake Onuma, from which the water is led in a flue some 6 ft. square and 3 miles long to a point where a fall of 220 ft. is obtained. The average flow of water is 140 square ft. per minute. The total horse-power available is 3,500 h.p., but at first only 1,500 h.p. is to be supplied. The cost per horse-power supplied is to range from 5 yen up to 15 yen (10s. to £1 10s.) per 24 hours, which will effect a saving of over 35 per cent. as against the present cost of horse-power using steam boilers. The capital of the company is £100,000. This concern has already taken over the electric lighting of Hakodate, and it is hoped will electrify the present horse tramway system.

LEEDS: *Tramway Extension.*—The Corporation are applying to the Board of Trade for an extension of the period for the construction of a number of tramway extensions in the city.

LITTLEBOROUGH: *Electricity Supply.*—The Rochdale Electricity Committee have now decided to give a supply in bulk to the Littleborough Urban District Council, subject to satisfactory arrangements of details of agreements. Three-phase alternating current will be supplied at 3,000 volts at a price of 3d. per unit for the first hundred hours per quarter, and 1d. per unit afterwards.

LONDON: *London County Council.*—At Tuesday's meeting of the Council the estimates sent in by the Highways Committee of £1,290,000 for capital expenditure for the year 1908-9 in the purchase of tramways undertakings, reconstruction for electrical traction and construction of authorised new tramways, including acquisition of sites for the erection of car-sheds and sub-stations, and the erection and equipment of the generating station at Greenwich were discussed at some length and finally approved.

City of London Tramways.—At the meeting of the Court of Common Council on Thursday, a petition was presented from ratepayers on the east side of Bishopsgate Street Without in opposition to the proposal to widen the thoroughfare in order to admit of the introduction of tramways.

North London Tramways.—Comment is made upon the fact that in the reconstruction of the London County Council Tramways to Finsbury Park, the track work stops short of the track of the Metropolitan Electric Tramways system, serving the outer northern districts by several feet. Hopes had existed that through running would have been arranged between the London County Council and the Metropolitan Electric Tramways, Ltd.

Fulham.—The accounts of the electricity undertaking for the year ended March 31st have closed with a surplus of £1,408, of which £1,000 is to be transferred to machinery maintenance and reserve account, and the balance is to be retained on revenue account. The gross expenditure for the year shows a reduction on the estimates, and the estimated receipts have been exceeded by £270. The total expenditure on public lighting is less by £460 than the estimates, notwithstanding a large amount of extra work carried out.

Marylebone.—A statutory declaration has been received from the secretary of the Reason Manufacturing Co., Ltd., that the amount of the profit accruing to Mr. A. Wright from transactions between the Council and the company up to March 31st last was £36 2s. This sum, according to arrangement, is to be deducted from Mr. Wright's account.

Poplar.—The Borough Council has applied to the London County Council for permission to lay electric lighting mains in certain main sewers. The Mains Drainage Committee recommend that its application be granted on payment of a nominal rent of £1 a year in respect of each way leave.

Stepney.—Relative to the contract which the Borough Council have entered into with Messrs. Willans & Robinson, Ltd., for the generating plant at the "Blyth's Wharf" power house, the specification required the contractor to tender alternatively for condensers of the "Contraflo" type and for condensers of the ordinary type, and stipulated that either type of condenser should be provided with a Parsons' vacuum augmenter, which would be required more particularly with the ordinary type. In tendering, Willans & Robinson, Ltd., offered to deduct from the amount (£28,140) of their tender £120 if the vacuum augmenters were omitted. The firm has now suggested that they should fit, without vacuum augmenters, condensers with a larger number of tubes than those tendered for. The Electricity Supply Committee has decided that subject to the contractors giving an undertaking to maintain their guaranteed steam consumptions and efficiencies as provided by the contract (notwithstanding the increase in the tube surface and size of air-pump), the suggestion should be agreed to, the £120 mentioned above not to be deducted.—The Committee has resolved that legal proceedings be commenced against the City of London Electric Lighting Co., Ltd., for restraining the company from continuing the supply of electrical energy for consumption within the Tower of London, which, it is contended, is outside the company's statutory area of supply and within the area of the Borough Council.

MANCHESTER: *Electricity Accounts.*—The accounts for the year ended March 31st, 1908, have been published. The revenue amounted to £384,602, and the working expenditure to £219,358. From the gross profit of £165,244 interest on mortgage debit sinking fund and instalment of loans repaid to works commissioners absorb £145,701, bringing a net surplus of £19,543. Out of this surplus the sum of £1,998 has been appropriated for extensions of works, for which borrowing powers cannot be obtained. £10,000 has been paid to the City fund in the aid of rates, and the balance of £7,545 has been carried to the reserve fund.

Telephone Junction Fee.—Heston Moor and Eccles have now been included in the Manchester central group of exchanges, and the 1d. junction fee for communication between these two places, which has been charged hitherto, is abolished. It is also intended to include Sale and Urmston in the same manner.

New Tramway Shed.—A new car-shed in Princess Road, Moss Side, capable of accommodating 250 cars, is now in the course of construction.

MIDDLESEX: *Tramways.*—The Council has confirmed a resolution previously passed that application be made to the Board of Trade for an order extending by £100,000 the borrowing powers of the Council as authorised by the Middlesex Light Railway Orders, 1903 and 1907. The County Council approved of the whole of the cost incurred by the Metropolitan Electric Tramways, Ltd., in promoting the Metropolitan Electric Tramways Act, 1905, amounting to £1,835, being charged by the company as part of the capital expenditure in connection with the Edmonton tramways. With reference to the dispute which has now been going on for the last five years between Messrs. Wm. Griffiths & Co., Ltd., and the County Council with respect to tramway contracts, the matter has now been amicably arranged by Messrs. Wm. Griffiths having agreed to accept £2,000 in full discharge of all claims in respect of the Great North Road lines. The original claim by Messrs. Griffiths was for £10,921 in respect of delays to which they alleged they were put.

RAVENSTHORPE: *Public Lighting.*—The Electrical Engineer has reported against the street lighting by electricity, and recommends that the Council should ratify their agreement with the gas company for the public lighting.

SWANSEA VALLEY: *Tramways.*—The first section of the Glamorgan County Council Tramways, which will connect Swansea with the Swansea Valley, will shortly be opened. The line will be operated by the Swansea Tramways and Improvements Co., in connection with their Swansea system. The Board of Trade inspection will take place in a few days.

TURKEY: *Electric Tramways.*—A proposal has been made by a Turkish contractor to construct an electric tramway about five miles long from the Monastir railway station through the town to the large village of Magarevo, but so far no satisfactory terms have been offered. The project has not yet been thoroughly worked out either from the technical or commercial point of view, and it is not certain whether the water supply from which it is supposed to obtain power is sufficiently constant.

WALTHAMSTOW: *Electricity Works.*—The excavations and the construction of the foundations for the new chimney shaft, boilers, &c., at the generating station, are to be carried out by direct labour. The Electrical Engineer has been instructed to substitute "Osram" lamps for 32 c.p. lamps on lamp-columns in such parts of the district as he thinks suitable.

WILLESDEN: *Tramway Speeds.*—The Board of Trade has refused to sanction an increase of speed for the next twelve months upon the Metropolitan Electric Tramways system in Willesden.

WIMBLEDON.—A letter has been received from the solicitor of the London & South Western Railway Co. notifying the Council that the company will not require a supply of electrical energy at their Wimbledon Park works after December 31st, 1908. Subject to protective conditions, the General Purposes Committee have given to the London United Tramways, Ltd., permission to lay a single line of tramway connecting the west track of the tramways in Hill Road with the south track of the tramways in Worple Road.

NEW COMPANY

BROWN & PARSONS.—This company was registered on June 25th with a capital of £1,000 in £1 shares, to acquire the business carried on at 63 The Parade, Leamington, as Brown & Parsons, and to carry on the business of electrical and mechanical engineers, manufacturers of electrical or other machinery, accessories and instruments, &c. The subscribers are :—R. N. Newton, H. Robinson, G. H. Salmon, Mrs. E. Brown, C. J. Passey, F. E. Brown, and H. B. Matthews. No initial public issue. The number of directors is not to be less than three nor more than five; the first are F. E. Brown (managing director), and two others to be appointed by the subscribers. Remuneration of F. E. Brown £150 per annum and 10 per cent. of the net profits after 10 per cent. is paid on the ordinary shares. Registered by S. Mandale, 41-2 Temple Street, Birmingham.

Digitized by Google

TENDERS INVITED AND PROSPECTIVE BUSINESS

Miscellaneous

BRAUNTON.—A report has been submitted to the Parish Council outlining a scheme of electric lighting. No decision has been arrived at pending the obtaining of further information as to the merits of gas compared with electricity.

BURNLEY.—The Tramways Committee has decided to purchase five new cars.

WILLESDEN.—A telephone exchange is to be erected by H.M. Office of Works, Storey's Gate, S.W., at Willesden.

Generating Stations, Sub-stations, Mains, &c.

COVENTRY.—The increasing demand for electricity at Coventry both for lighting and power purposes has led to the Corporation making application to the Local Government Board for sanction to the borrowing of £35,000 for extensions to the distributing plant, including the laying of mains in the outlying district. Altogether about £25,000 of the total amount is required for this purpose, but it is not intended to spend all this sum at once, but only as the extent of the demand warrants it. On Friday last, Mr. E. H. Tulloch, on behalf of the L.G.B., held an inquiry into the application. There was no opposition. It was mentioned that £2,000 was required for motors, in which branch a very lucrative business is being done.

DENMARK.—H.M. Consul at Copenhagen (Mr. L. C. Liddell) reports that tenders are invited by the Copenhagen Lighting Department for the supply of electric cables, required during the period August, 1908, to August, 1909. Tenders, marked "Tilbud paa Kabler," and addressed to the "Direktorenfor Belysningsvaesenet, Raadhuset, Copenhagen," will be received up to noon on July 8th.

DUBLIN.—The Lighting Committee invite tenders for the supply of sub-station switchboard transformers and accessories. Full particulars from the City Electrical Engineer, Fleet Street, fee £1 1s., returnable, and tenders to the Chairman of the Lighting Committee, 3 Cork Hill, Dublin, by July 13th.

FARNWORTH.—The local District Council have applied to the Local Government Board for sanction to borrow £7,000 for purposes of electric lighting. An inquiry into their application has been fixed for July 7th, to be conducted by Mr. H. Shelford Bidwell.

FELIXSTOWE.—Tenders are invited for overhead lines and house services. Particulars from Mr. R. P. Wilson, 66 Victoria Street. Fee, two guineas (returnable). Tenders by July 15th (see an advertisement this week).

ILFORD.—The Education Committee has requested the Council's Electrical Engineer to prepare an estimate for the installation of electric light at the Cleveland Road Board School.

LONDON: *London County Council.*—The Council invite tenders for the manufacture and delivery of high-tension main switchgear and low-tension auxiliary switchgear for the Greenwich generating station. Particulars from the Clerk, fee £2, returnable, and tenders by July 7th.

The Council invited tenders for the supply and delivery of about 100,000 tons of washed singles for the Greenwich generating station. Delivery to be made between August 1st, 1908, and July, 1909. Particulars from the Clerk to the Council, and tenders by July 7th.

Hackney.—The Finance Committee of the Borough Council have submitted estimates for a number of extensions of mains, estimated to cost £251. The Electric Lighting Committee has resolved to invite tenders for painting and repairing work at the electricity and destructor works.

Islington.—A natural draught cooling tower is required by the Eden Grove works. Particulars from the Chief Engineer, and tenders to the Town Clerk by July 16th.

Marylebone.—Tenders are to be invited for the re-arrangement of Aybrook Street sub-station buildings for the purpose of properly concentrating the electrical distributing staff under healthier conditions. The L.C.C. is to be asked for a loan of £5,000 to carry out the work.

St. Pancras.—Additions are to be made to the low-tension switchboard at the King's Road generating station. Particulars from the Electricity Department, 37 Pratt Street, Camden Town, and tenders to the Town Clerk by July 13th.

MANCHESTER.—Mr. A. J. Drury held a Local Government Board inquiry, on Thursday, into the application by the Corporation for sanction to borrow £130,500 for extensions to the generating plant. The Deputy Town Clerk, in presenting the case for the loan, stated that the output during the last year was 31 per cent. higher than that during the previous year, and that since 1904 the number of consumers had increased from 5,171 to 7,519. The number of connections in the equipment of 8 c.p. lamps had increased from 6,007 to 1,238,000, and the output had increased from 6,292 kw. to 10,288 kw. The number of units sold had increased from 29,000,000 to 63,000,000, and the gross revenue amounted to £384,000 compared with £267,000. The new loan was for the provision of 12,000 kw. of new generating plant of which half would be installed during the winter of 1908-9, and the other half the following year. The proposed loan also includes the sum of £1,000 for feed-water heaters at Dickinson Street station, and £13,500 for an artesian well at Stuart Street station. The application was supported by the Property Owners' Association and the Manchester Retail Traders' Association.

ODESSA.—The Town Council invites tenders for the installation and working, as a concession, of an electric station, with a capacity of not less than 6,000. Tenders to the Town Uprava (Executive Committee of the Town Council) by 12 o'clock noon of the 1-14 September of the present year, 1908. A deposit of a thousand roubles must be made as security for their proposal. Detailed particulars of the concession and other information may be obtained of the Building Department of the Town Uprava on working days (i.e., days when members are in attendance), from 1 to 3 clock.

WIMBLEDON.—The Local Government Board has sanctioned the borrowing by the Borough Council of the following amounts for work in connection with the electricity undertaking:—£2,606 for new remote control switchboard, and gallery and stairway at electricity works, Durnsford Road; £1,240 for extensions of buildings and foundations for engine and boilers (after deducting £310, outstanding debt on old buildings); £7,575 for new 1,000-kw. turbo-alternator, with platforms, cables, &c.; £4,710 for two water-tube boilers and economisers.

Wiring

ANERLEY.—The Managers of the North Surrey District School are about to provide additional class rooms and central hall at the school. The plans have been prepared by Mr. Cecil A. Sharp, architect, 11 Old Queen Street, Queen Anne's Gate, S.W.

BLACKBURN.—The Town Council recommend the erection of a new sessions house and police station and large public hall on a site now in their possession, as suggested in scheme prepared by the architects.

BLACKHEATH.—The Managers of the St. John's Church of England School, Russell Place, have obtained a site on which they propose to build a new school. Plans are in course of preparation.

BRADFORD.—Tenders are invited for an electric light installation at the new Nurses' Home and Isolation Block of the City Hospital, Leeds Road. Full particulars from the City Architect, Whitaker Buildings, Brewery Street.

BRISTOL.—*Extension, &c., of Royal Infirmary.*—Architect not yet appointed. W. E. Budgett, secretary to hospital.

The Bristol Co-operative Society, Ltd., are about to build a bakery at Whitehall, St. George, at a cost of £40,000. Mr. T. H. Smith is the general secretary of the Society.

BRYNNA.—Mr. J. T. Jenkins, architect, Porth, Rhondda, has prepared plans for the erection of 30 houses, and the contract for the building has been let at £5,200 to Mr. T. W. Jones, Pontycymmer.

CARDIFF.—Messrs. J. Allen, Ltd., Cardiff, have secured the contract at £3,000 for erecting new bottling stores for the Anglo-Bavarian Brewery, Ltd. Mr. E. G. C. Down, 31 High Street, Cardiff, is the architect.

DENHAM, BUCKS.—Alterations and additions are to be made to Mr. C. N. Newton's country house, after the plans of Mr. Anthony Wilson, architect of 1 Hare Court, Temple, E.C. The cost will be about £2,000.

DARTFORD.—Tenders are shortly to be invited for the erection of a church. The vicar-designate is the Rev. F. V. Baker, Christ Church, Dartford.

EAST HAM.—Mr. F. Hamlett, builder, Barking Road, E., is about to erect twenty-one houses in Montpelier Gardens. The rebuilding of the Red Lion beer-house, in High Street South, will shortly be commenced.

FELTHAM.—Middlesex County Council has decided that the infants' department of the Council school be enlarged, and Mr. H. G. Crothall, Middlesex Guildhall, Westminster, architect to the Education Committee, has been authorised to prepare the necessary plans and specifications.

GILLINGHAM.—A theatre of varieties is proposed to be built almost in the centre of the town, and it is hoped that it will be possible to give the first performance early in 1909. Mr. W. J. Mackay is at the head of the scheme.

GRINDLEFORD.—Mr. E. R. Sutton, architect, Nottingham, has prepared plans for a new church. It is proposed to commence with a chancel and a temporary nave.

HAMPTON.—A new church, with a seating accommodation of approximately 600, is in course of erection. The cost of the completed design (prepared by Messrs. Greenaway & Newberry, architects, 21 Queen Anne's Gate, S.W.) is £7,000. Messrs. J. Dorey & Co., of Brentford, are the builders.

HOUNSLOW.—Mr. Charles Burton, architect, 65-66, Chancery Lane, W.C., has prepared plans for the erection of a music hall in High Street, and is submitting them to the local authorities for approval.

LITTLEOVER.—A south aisle and chancel are to be added to the Church of St. Peter at a cost of £2,000. The architects

Digitized by Google

are Messrs. Naylor & Sayle, of Derby, and the contractors are Messrs. Joseph Parker & Son, of Derby.

LONDON, E.—Messrs. John Hall & Son are about to erect a steam motor garage, and additions to Sun Flour Mills, St. Leonard's Street, E.

Additions are to be carried out to St. Matthias' Schools, in Grundy Street. Messrs. Fred & T. Thorne, of 266 Manchester Road, E., are the builders.

N.—Messrs. W. V. Aldridge & Son, wholesale drysalters, of Islington Green, are to re-erect that portion of their premises recently destroyed by fire.

Plans have been prepared by Messrs. Greenaway & Newberry, 21 Queen Anne's Gate, S.W., of additions proposed to be made to St. John's Road Workhouse, Upper Holloway.

N.E.—Two factories are to be erected at Hackney, one in Foulden Road, by Mr. C. G. Smith, architect, 56 Cannon Street, E.C., and the other in Kingsland Road, by Mr. W. H. Cone, builder, 80 Alkam Road, Dalston.

N.W.—Messrs. Unwin, Parker & Unwin, architects, of Wildes Farm, North End, are about to develop several new roads at the Hampstead Garden Suburb. They have also prepared plans for the erection of 13 houses in Hampstead-Way.

Sanction has been granted, by the local authorities concerned, to Mr. R. Vernon Hart, builder, of Burgess Park, N.W., for the erection of houses in Golder's Green Road.

Eight houses are to be erected in Middleton Road, Hendon. Mr. E. Streather, builder, of Sanderstead Station, Croydon, is the contractor for the work.

The Improved Industrial Dwellings Co., Ltd., 33 Finsbury Square, E.C. (Mr. Arthur Moore, sec.), has decided to erect dwellings in Willifield Way, and Asmuns Hill, Hendon.

S.E.—The Governors of the Dulwich College Estates have concluded terms for the erection of two hundred houses in Woodwarde Road, and a number of other houses to be erected under current building agreements. Mr. W. G. King is the Secretary and General Manager of the Estates.

The Managers of Christ Church Church of England School, Bear Lane, Southwark, have decided to carry out alterations (including the erection of a hall) to their school. The plans have been forwarded to the Board of Education for approval.

Messrs. Norfolk & Prior, architects, Catford, have prepared plans for twelve houses on the west side of Muirkirk Road, and twenty-two houses on the south side of Ardoch Road, Lewisham.

Messrs. W. J. Scudamore & Sons, builders, of 13 Manor Lane, S.E., are about to erect five houses on the north side of Chalcroft Road, Lewisham, and five houses on the north-east side of the same road.

S.W.—Messrs. Elms & Jupp, architects, 25 Sackville Street, W., have prepared plans for the formation of a new street on the west side of Church Street, Fulham Road.

Alterations, &c., are to be carried out at the Chelsea fire station, for the L.C.C.

The Chelsea Guardians recommend that electric light be fixed in various parts of the infirmary.

Messrs. Chapple & Utting, builders, of 24 Wavertree Road, Streatham, are about to erect fourteen houses on the north side and six houses on the south side of Wavertree Road, S.W.

The proprietors of Clapham College, Nightingale Lane, Balham, have decided to extend their premises. Messrs. Holliday & Greenwood, Ltd., Loughborough Park, S.W., are the contractors.

Additions are to be made to the Clapham Public Library, North Side, Clapham Common, by Messrs. J. Garrett & Son, builders, 83 Balham Hill, S.W.

Mr. J. C. Radford, architect, of 223 Upper Richmond Road, Putney, has prepared plans for the erection of houses, record office, and pavilion on Bank of England sports ground, Priory Lane, Putney.

Three shops and houses are to be erected in Tooting High Street by Messrs. Style & Winch, Ltd., brewers, Electric Avenue, Brixton, S.W.

Messrs. Ashton Webb & E. Ingress Bell, of 19 Queen Anne's Gate, Westminster, have prepared plans of a new vicarage to be erected in Margravine Road, Fulham, to abut upon St. Alban's Terrace.

W.—Housebreaking operations are proceeding at 125-6-7 Piccadilly. On the sites there are to be erected buildings in accordance with the plans of Messrs. Mewès & Davis, architects, 6 Dean Street, Soho, W. The builders are Messrs. Higgs & Hill, South Lambeth Road.

A scheme is on foot for the re-erection of Princess's Theatre, Oxford Street. The Board of Directors consists of the following:—Mr. Joseph Lyons (chairman), Mr. Cecil Raleigh, Mr. Patterson, Lord Elcho, and Mr. Albert Gilmer, who will also act as business manager.

W.C.—Messrs. Barlow & Roberts, builders, 15 Red Cross Street, S.E., are negotiating for the acquirement of a site in Gate Street. The area is about 1,000 square feet, and will probably be utilised for building purposes.

MITCHAM.—A church, vicarage, and parochial hall, in connection with St. Barnabas', Mitcham, are to be erected at a cost of £12,000. It has been decided to commence with the parochial hall, which is to cost £3,200. The vicar of St. Barnabas' is the Rev. E. J. Baker.

MOUNTAIN ASH.—A mixed school is to be erected at Abercynon to accommodate 350 children. The plans have been drawn up by Mr. W. H. Williams, Town Hall, Mountain Ash.

ROTHERHAM.—Messrs. Owen and Dyson, Rother Ironworks, are to make some additions to their offices.

Alterations and additions to the Rotherham Grammar School are about to be put in hand by the Governors.

A new secondary school for girls at Rotherham is to be erected by the Local Education Committee (Mr. J. H. Mair, Secretary).

SALFORD.—The "White Horse Inn," Clarence Street, Broughton, is to be rebuilt.

SKEGNESS.—The Baptists propose to erect a new church, and have acquired a site. Sir Joseph Bright, J.P., of Nottingham, is taking a prominent part in the movement.

SOUTHALL.—A new school is to be erected by the Middlesex County Council to accommodate about 800 children. Mr. H. G. Crothall, Middlesex Guildhall, Westminster, Architect to the Education Committee, is to prepare plans, and tenders are to be obtained for the work.

STOCKTON-ON-TEES.—The Post Office is to be enlarged by H.M. Office of Works, Storey's Gate, S.W.

TOTTENHAM.—Building operations in this district are fairly brisk. Mr. G. W. Rowley, builder, 278 Philip Lane, Tottenham, N., who has recently put up a large number of houses, has decided to erect a further forty-seven residences in Rosebery Avenue, and sixteen in Gorleston Road.

Mr. G. W. B. Bolton, architect, of 11 and 12 Finsbury Square, E.C., has prepared plans for a block of flats in High Road. Owing to technical reasons the plans have not yet been passed.

Additions are to be made to St. Ignatius' College, High Road, South Tottenham, and to St. Mary's Priory, St. Anne's Road.

TWICKENHAM.—Electric lighting is to be installed at the Town Hall, the contractors being the Twickenham and Teddington Electric Light Co., Richmond.

The District Council has agreed to install electric light in the Town Hall, and has passed a scheme submitted by the Twickenham and Teddington Electric Light Co. There was considerable discussion at the last meeting of the Council on a recommendation of the Highways Committee to light the new isolation hospital with electricity. It was proposed by the committee to take the current required from the Council's sewage works, and, with this object, to spend a sum not exceeding £1,000 on doubling the generating plant at the works. The recommendation was carried.

WAKEFIELD.—The Wakefield & District Small-Pox Isolation Hospital Committee have obtained sanction to borrow between £10,000 and £11,000 for the erection of an isolation hospital at Carr Gate.

WALLINGTON.—The Wallington Congregationalists are raising money for the erection of a new church. A site has been obtained, and it is hoped that building operations will be shortly commenced. Communications may be addressed to Rev. G. Mannington.

WALTHAMSTOW.—Mr. H. Brodey, architect, 259 High Street, Walthamstow, is about to erect seven houses in Pentire Road. He has also prepared plans for the conversion of stables into flats in Randolph Road. These are still under the consideration of the local authorities.

WORTHING.—A site has been obtained on the sea front for the erection of a convalescent home in connection with the Royal Surrey County Hospital. Mr. Shepherd some few months ago gave about £10,000 for the building and endowment. The erection will be commenced when a sum of about £500, the balance of the purchase money of the site, is raised by subscription. Mr. E. Gibson is honorary secretary.

TENDERS RECEIVED AND ACCEPTED

AUSTRALIA.—The Queensland Postmaster-General's Department has accepted the following tenders:—British Insulated & Helsby Cables, Melbourne, lead-covered cable at £490, £240, £140, and £115 per mile respectively for 208 pair, 78 pair, 39 pair, and 26 pair cable; Western Electric Co., Sydney, 3,492 yards of 104 pair lead-covered cable at £464 19s. total; W. T. Henley's Telegraph Works Co., Ltd., Melbourne, 52 pair lead-covered cable at £176 per mile; C. E. Burnay, Brisbane, 13 pair lead-covered cable at £74 per mile

The Electric Lighting & Traction Co. of Australia have placed an order with Messrs. Bellis & Morcom, of Birmingham, for two 1,100-h.p. engines coupled to 750-kw. Brush D.C. generators, in addition to a surface condensing plant with motor-driven air and circulating pumps.

AUSTRALIA.—The tender of Messrs. Siemens Bros., London, for the manufacture and laying of two new cables between Victoria and Tasmania, has been accepted by the Federal Government at £47,955. The Postmaster-General of Australia

Digitized by Google

has accepted the tender of the Western Electric Co., Sydney, for the supply and delivery of 20 miles of telephone cable, at £490 per mile (a total of £9,800), and 150,000 paper sleeves.

BOLTON.—The Electricity Committee has accepted the tender of the British Insulated & Helsby Cables Co., of Prescott, for 12 months' supply of cable; that of the British Westinghouse Electric & Manufacturing Co. for the supply of a combination booster; and that of Mr. H. Critchley for painting the interior and exterior of the electricity offices.

DARTFORD.—The Council has accepted the following tenders for annual supplies to the electricity department:—House service cable, jointing material, and accessories, Johnson & Phillips, Ltd., £159; general stores, S. W. Gibson & Co., £67 10s.; 2,500 to 3,000 tons South Hetton rough small coal, Beadle Bros., Ltd., 14s. 6d. per ton; 2,000 to 2,500 tons of coke breeze, E. J. & W. Goldsmith, Ltd., 8s. 6d. per ton.

LONDON: *Hackney.*—The Electric Lighting Committee has decided to accept the tender of W. G. Beaumont & Sons, Priory Works, Priory Street, Bromley-by-Bow, at £121 11s. 10d., for the painting of arc lamp posts and switch pillars. This was the lowest of eight tenders received.

MIDDLESEX.—The County Council received the following tenders for the construction of the tramways along Friern Barnett Road from the Orange Tree Inn, Friern Barnet, to New Southgate Station, and from the Orange Tree Inn, Friern Barnet, along Woodhouse Road to Great North Road, Finchley:—

	£	s.	d.
Adams, Thomas	32,668	1	8
Dick, Kerr & Co. (accepted)	31,431	7	10
Fasey, A., & Son	37,161	14	0
Ford Clift	31,431	7	10
Holloway & Co.	35,063	15	11
Law & Co.	35,855	13	10
Mowlem & Co.	33,704	12	6
Wall, C., Ltd	36,364	17	1
Wimpey & Co.	34,048	17	0

The estimate of the County Engineer for the work was £33,524 15s. 9d.

SOUTH AFRICA: *East London.*—The tender of Messrs. W. Bain & Co., of Coatbridge and Johannesburg, has been accepted for the structural steel work at £5,101, in connection with the new power station which the East London Council is erecting. The same firm's tender for a coal transporter at a cost of £2,805 has also been accepted.

STOCKHOLM.—The Oerlikon Co. have received an order for two 6,000 kw. turbo-generators. The sets will generate at 6,000-6,500 volts 25 cycles, and will give their full output at a power factor of 0·85 at a speed of 750 r.p.m.

UNDERGROUND RAILWAYS CO. OF LONDON, LTD.—An order for a large number of signs with the word "Underground" has been placed with Messrs. O. C. Hawkes, Ltd., of Birmingham, by the Underground Electric Railways Co. of London, Ltd. Some of these signs, which are for erection outside the stations of the Underground Electric Railways Co., will be made with three faces, so that the word can be read from the front and from either side, whilst others are to be V shape. It is calculated that about 70,000 sq. ft. of plate glass will be utilised. Messrs. O. C. Hawkes, Ltd., will carry out the complete contract, including the ornamental ironwork and electrical equipment.

WIMBLEDON.—The Electric Lighting Committee of the Borough Council has decided to accept the following tenders:—Supply of coal for electricity works for year ending June 30th, 1909, Charrington, Sells, Dale & Co., "Mapperley small nuts," 15s. 9d. per ton; supply of arc lamp globes for year ending March 31st, 1909, Edward J. Shaw & Co.

COMPANIES' MEETINGS AND REPORTS

ANGLO-ARGENTINE TRAMWAYS CO.—At an extraordinary meeting on Tuesday, resolutions were carried approving a provisional agreement with the Compagnie Générale de Tramways de Buenos Ayres, for the acquisition by the company of 24,007 six per cent. preference shares, and 20,007 ordinary shares, both of £5 each, and constituting all the issued share capital of the Buenos Ayres Electric Tramways Company (1901), and the entire undertaking of the Belgian Argentine Tramways Company; and authorising the division of the £5,000,000 new ordinary shares into £2,500,000 five per cent. cumulative third preference shares, and £2,500,000 ordinary shares, the payment for the above properties and the Buenos Ayres and Belgrano Tramways Company's undertakings to be effected as to one-half in third preference shares and as to one-half in ordinary shares.

BUENOS AIRES GRAND NATIONAL TRAMWAYS.—At the meeting on Tuesday the report and accounts, given in our last issue, were adopted. Mr. Irving Courtenay, in presenting the accounts, said he thought the shareholders would consider them satisfactory under the transition circumstances. Having gone through the accounts he gave warning against exaggerated expectations for the future. The traffic upon the system as a whole continued to show an increase month by month as compared with the previous year, but a new and active competition upon the part of a rival line was affecting several of their services. It was too soon to form a definite idea of what the effect would be upon the current financial year, but he feared it would tend to postpone the time when they would be in a position to pay a dividend upon the ordinary shares. They were working in harmony with the consultation of the various tramways in Buenos Aires, a consultation which, since he had studied the tramways situation on the spot, he had always been of the opinion was bound to come.

GLOBE TELEGRAPH & TRUST.—At the ordinary general meeting held on Tuesday, Lord Tweeddale stated that the receipts for the year, after deducting expenses, amounted to £210,295, of which £131,770 had already been absorbed in dividends. A final dividend on the ordinary shares of 5s. 9d. per share was recommended, making a total of 5¾ per cent. for the year. £27,206 are to be carried forward. The report was adopted.

INDIA RUBBER, GUTTA PERCHA, & TELEGRAPH WORKS CO.—At the half-yearly meeting held yesterday, Major Darwin, in bringing forward the recommendation for a 2½ per cent. interim dividend, referred to the symptoms now being shown of a permanent lowering of the prices of raw material. At an extraordinary general meeting which followed, a resolution was passed under which the directors were empowered to issue fresh capital.

INDIAN ELECTRIC SUPPLY.—The report for 1907 shows that up to June 30th, 1907, the capital expenditure amounted to £122,402, and that the revenue account was opened on July 1st. The working in India for the half year of 1907 resulted in a loss of £2,043, which was increased to £6,681. After meeting London expenses and interest on construction debenture stock. Further capital will have to be raised to pay off the indebtedness incurred, and to provide for extensions of the mains. Arrangements have been made for the financial requirements of the company until the end of 1908.

JOHNSON, LUNDELL ELECTRIC TRACTION.—The accounts for the 21 months to May 30th show a balance at debit of profit and loss account of £558,555. The report stated that funds are being conserved in order to keep the patents alive until a more favourable time, and arrangements are being made to give effect to the offer of the principle promoters to make good to the shareholders the profit made by them in the promotion. The meeting was on Tuesday adjourned to enable these arrangements to be completed.

J. G. WHITE.—At the ninth ordinary meeting held on Monday, the report, abstracted on page 982 of our last issue, was adopted. Mr. J. G. White, who presided, called attention to the satisfactory way in which difficulties arising from severe competition and stringency in the money market had been met. He was pleased to say that business in hand was sufficient to ensure thoroughly satisfactory profits for the current year, and negotiations for other important business were progressing favourably.

COMPANY MORTGAGES, &c.

BOURNEMOUTH & POOLE ELECTRICITY SUPPLY CO.—Particulars have been filed pursuant to Section 14 (4) of the Company's Act, 1900, of a series of debentures for securing an amount not exceeding half the subscribed capital for the time being, of the company, created by resolutions dated March 5th, 1900, July 16th, 1903, and May 21st, 1908. The present subscribed capital of the company is £375,000. The property charged under the new debenture is the company's undertaking and property present and future. There are no trustees.

LA CAPITAL TRACTION & ELECTRIC LIGHTING CO. (BUENOS AIRES).—A trust deed was registered on May 20th, supplementary to two trust deeds, dated December 21st, 1900, and November 11th, 1907, securing £800,000 debentures. The property chargeable is the company's undertaking and assets present and future, and the trustees are W. Trotter, Basildon House, and R. Fleming, 2 Princes Street, E.C.

LANCASHIRE DYNAMO & MOTOR CO.—£500 5 per cent. first mortgage debentures, part of series created to secure £75,000 charged on two plots of land in Trafford Park, Manchester, with the premises and machinery thereon, and the company's other assets and undertaking, except new capital, were issued on June 3rd. There has previously been issued of the same series £68,000. The trustees are E. F. Sheppard, 55 King Street, Manchester, and A. Tongue, 86 King Street, Manchester.

APPOINTMENTS AND PERSONAL NOTES

The Bury Electricity Committee have decided to increase the salaries of the works and mains superintendents from £150 per annum to £180 per annum in each case.

Mr. W. T. Maccall, of the Woolwich Polytechnic, has been appointed head of the electrical engineering department at the Halifax Municipal Technical School at a salary of £200 per annum.

Digitized by Google

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival quoted on Tuesday night, was £58 15s. to £59 5s. per ton.

AGENCY.—Messrs. Pooley & Austin, of 25 Victoria Street, S.W., inform us that they have been appointed sole agents in London and the Home Counties for Messrs. Engineering Instruments, Ltd., manufacturers of totally enclosed motor control gear for direct and alternating current.

CHANGE OF ADDRESS.—Messrs. Arc Lamps, Ltd., have now removed from Camden Town to their recently completed factory at St. Albans. They wish to notify their clients that in order to facilitate the securing of spares, Messrs. Frampton & Paine, of 29 Old Queen Street, Westminster, their sole selling agents for London and the South of England, hold a stock of carbons, globes, and other spare parts.

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—At the London Bankruptcy Court, on Thursday, Thomas Clement Hodgkinson, trading as "The Electro-Neurotone," at 186 Goldhawk Road, Shepherd's Bush, applied for his discharge. The Official Receiver in his report said the receiving order was made on May 2nd, 1906, and at the first meeting of creditors debtor returned his liabilities at £541, and assets at £235. Proofs were lodged, however, for £1,698, and a dividend of 1s. 9d. in the £, was paid. The only offence against the Bankruptcy Acts reported was that the assets were not equal to 10s. in the £. No creditors opposed the discharge. The Registrar said the only alternative to two years' suspension the law allowed was that the debtor should consent to judgment being entered against him for a certain sum. He would grant an adjournment in order that the debtor might consider whether he would pay £20 in order to bring the dividend up to 2s. The matter was accordingly adjourned.

A meeting of the Totnes Electricity Supply Co., Ltd., will be held in room No. 425, Salisbury House, London Wall, on July 30th, at 11.15 a.m., to hear the liquidator's account of the winding up.

A meeting of the Chelmsford Electric Lighting Co. will be held in room 425, Salisbury House, London Wall, on July 30th, at 11.15 a.m., to hear the liquidator's account of the winding up.

A meeting of the "Z" Electric Lamp Syndicate, Ltd., will be held at Orient House, New Broad Street, London, on July 28th, for the purpose of hearing the liquidators account of the winding up.

T. A. Evans, carrying on business under the name of T. Arthur Evans & Co., electrical and mechanical engineers and contractors at Swansea, has been adjudicated as a bankrupt.

PARLIAMENTARY INTELLIGENCE

CENTRAL IRELAND ELECTRIC POWER BILL.—The Dublin Corporation and the Dublin and Alliance Gas Co. have petitioned against the Central Ireland Electric Power Bill.

LIVERPOOL CORPORATION BILL.—This Bill was under consideration of the Police and Sanitary Committee of the House of Commons last week, and has been sent forward for third reading. Part 3 proposes the construction of tramways in the district of the Litherland Urban District Council, and the sum of £2,900, repayable in 30 years, is to be borrowed. The period for construction is five years.

METROPOLITAN DISTRICT RAILWAY.—In answer to a question in the House of Commons on Thursday, Sir H. Keighley stated that the Board of Trade were informed that the Metropolitan District Railway Co. were preparing to change the pneumatic method of operating the sliding doors on their trains to hand operation.

PAISLEY AND DISTRICT TRAMWAYS ORDER CONFIRMATION BILL was read a second time in the House of Lords on Tuesday, and the Ayr Corporation Tramways Order Confirmation Bill was read a third time.

TRAMCAR ACCIDENTS.—In reply to a question in the House of Commons last week, Mr. Churchill stated that the number of accidents reported to the Board of Trade as having occurred through persons being knocked down or run over by tramcars in the year were as follows:—Number of accidents, 1,329; killed, 105; injured, 1,003; uninjured, 221.

WEST LONDON, BARNES, AND RICHMOND TRAMWAYS BILL.—The promoters of the West London, Barnes, and Richmond Tramways Bill have intimated their intention not to proceed with the measure this session. The Bill proposed the incorporation of a company with a capital of £240,000 in £1 shares to construct a network of lines in Richmond, Mortlake, Barnes, and Putney. The first directors of the company were to be T. W. Reynolds, A. H. Sanderson, F. E. Savory, and R. P. Sellon. The term of purchase was to be 60 years instead of 61, and provision was made for agreements to be entered into with the County of London Electric Supply Co. and the Richmond (Surrey) Electric Supply Co. Fifteen separate lines were described in the Bill.

The Blackburn Corporation and the London United Tramways Bills were read a third time in the House of Commons on Tuesday.

PROGRESS OF ELECTRICAL BILLS.—The North East Railway Co. Bill was read a third time in the House of Commons on Thursday.

The Lanarkshire Tramways Order Confirmation Bill was read a third time, and passed in the House of Commons on Wednesday.

UNOPPOSED BILLS.—The Macclesfield and District (Abandonment) Bill was ordered to be reported for third reading by the Unopposed Committee of the House of Commons on Wednesday last week. The Tramways Company, having been transferred to the Urban District Council, now seeks to relieve itself of the obligation to construct the lines, and at the same time seeks authority to transfer the Macclesfield Electric Lighting Order, 1901, to the Macclesfield Electric Light & Power Co., and to wind up the company.

The Bristol Tramways Bill has also been ordered to be reported for third reading by the Unopposed Committee of the House of Commons. This Bill seeks an extension of time for three years for tramways authorised in 1904.

MISCELLANEOUS CITY NOTES

BRUSH ELECTRICAL ENGINEERING CO.—An extraordinary general meeting is to be held on Tuesday next for considering resolutions regarding the consolidation of the non-cumulative 7 per cent. preference and ordinary shares, so that every three shares of 6s. 8d. shall form one fully-paid share of £1, and that the unissued shares shall be sub-divided so as to be also of £1 each.

HARPER ELECTRIC PIANO CO.—A dividend of 10 per cent. per annum on the preference shares is recommended for the half-year ended June 1st.

O. C. HAWKES, LTD.—A dividend of 5 per cent. per annum has been declared upon the preference shares for the half-year ended June 30th, also an interim dividend of 5 per cent. per annum upon the ordinary shares for the same period.

INDIA RUBBER, GUTTA PERCHA, & TELEGRAPH WORKS CO.—An interim dividend of 5s. per share, free of tax, is recommended upon the ordinary shares.

NOTTING HILL ELECTRIC LIGHTING CO.—The directors announce an interim dividend of 6 per cent. per annum, and a bonus of 1 per cent., making together 8s. per share on the preference shares, and 6 per cent. per annum upon the ordinary shares for the half-year ended June 30th.

VICTORIA FALLS POWER CO.—Mr. A. E. Hadley, who is known in connection with the Rosario Electric Co., has joined the Board.

APPOINTMENT VACANT.

BOROUGH POLYTECHNIC INSTITUTE,
103, BOROUGH ROAD, LONDON, S.E.

ELECTRIC WIRING INSTRUCTOR.

FOREMAN WIREMAN REQUIRED, qualified to give instruction in Electric Wiring (Elementary and Advanced) to City and Guilds of London Institute Technological Classes, on one or two evenings a week. Particulars of the appointment can be obtained by sending stamped addressed envelope to the Principal. All applications must be sent in by 11th July. Only selected candidates will be written to.

C. T. MILLIS,
Principal.

TENDERS INVITED.

FELIXSTOWE URBAN DISTRICT COUNCIL.

ELECTRIC LIGHTING.

THE URBAN DISTRICT COUNCIL OF FELIXSTOWE AND WALTON are prepared to receive tenders for the following:—

OVERHEAD LINES AND SERVICES.

Specifications, General Conditions, and Forms of Tender may be obtained on and after Saturday, 4th July, 1908, at the offices of the Consulting Engineer, Mr. Reginald P. Wilson, 66, Victoria Street, Westminster, on payment of a sum of two guineas.

This sum is required as a deposit, and will, after the Council shall have entered into a contract upon the tenders received, but not before, be returned to the tenderer, provided he shall have sent in a *bona fide* tender and shall not have withdrawn the same. In any other case the deposit will be forfeited.

The tenders must be sent in on the Official Form, and all instructions contained therein must be complied with.

Tenders, endorsed "Overhead Lines and Services," must be addressed to the Clerk, Felixstowe and Walton Urban District Council, and must be delivered at the Town Hall, Felixstowe, not later than 12 noon on Wednesday, 15th July, 1908.

The Council do not bind themselves to accept the lowest or any tender.

F. B. JENNINGS,
Clerk to the Council.

Town Hall, Felixstowe.
30th June, 1908.

PROPOSED NEW HOME FOR THE INSTITUTION OF ELECTRICAL ENGINEERS

THERE was a very good attendance at the special general meeting of members, associate members and associates of the Institution, which was held on Tuesday afternoon in the lecture theatre of the Medical Examination Hall to consider the following resolution:—

"That the purchase of the lease of the site and building known as the 'The Medical Examination Hall,' situate on the Victoria Embankment, now the property of the Royal College of Physicians of London and the Royal College of Surgeons of England, for the sum of £50,000, be sanctioned and approved, and that the Council be authorised to sell such of the investments of the Institution, and to make such other financial arrangements (including the disposal of the site in Tothill Street now owned by the Institution) as the Council may consider necessary for the above purpose."

The President, Col. CROMPTON, introduced the subject with a few preliminary words, and called upon the Hon. Treasurer, Mr. R. Hammond, to give a statement as to how the financial side of the question would be dealt with.

Mr. HAMMOND said that the capital requirements were as follows: For the purchase of the building, £50,000; and for the estimated cost of enlarging the theatre, six months' rent of the old premises, removal, painting, new furniture and bookshelves, £6,000; making a total of £56,000. The capital resources were as follows: Trustee investments, less the life compositions fund (possibly not deemed to be available for investment in the building), £17,701; deducting from this the sum of £862 transferred to the Kelvin Lecture Fund since the last accounts were made up, a sum of £16,839 is available, the realisable value of which may be taken as £15,000. To this last figure the following may be added: Value of investments made in current year, £4,000; estimated additional amount available by June 1st, 1909 (the date on which the £50,000 is payable), out of the usual increment, £4,000; and book value of the Tothill Street site, £19,260. This brings the total up to £42,260, leaving a sum of about £16,000 to be raised by a loan. Mr. Hammond then went into the probable income and expenditure in the year 1909, showing that whereas the probable expenditure amounted to over £13,500, the estimated income was only just over £13,000, leaving a slight deficit. He pointed out, however, that this deficit would almost certainly be converted into an increment by the further subletting of the upper floors of the building, as in the probable income he had included only the small sum of £650 for the rooms already let. He also pointed out that the Tothill Street site would, according to the best authorities, realise a larger sum than the book value.

The PRESIDENT then moved the resolution.

Mr. W. M. MORDEY (President-elect), in seconding the resolution, said that he was sure that if the building were purchased, it would be to the lasting good of the Institution. After mentioning the debt of gratitude owing to the Institution of Civil Engineers for the liberal use of their hall, he pointed out that the Institution was quite large enough to deserve a home of its own, not only for the purpose of holding meetings, but also for encouraging social intercourse among the members. The number of members was now over 6,000, as compared with the 8,500 members of the Institution of Civil Engineers. The idea of purchasing a building was no new thing, he said; since 1893, when the building fund was first started, the matter had been before the Council. The Tothill Street site was purchased in 1904 because it was the best they could find at the time, and land in Westminster was getting scarce. That site was by no means suitable, being far too small, but the purchase had not been unwise, as the site had paid a fair interest, and had increased in value. Five weeks ago the question of purchasing this building was first put before the Council, and the competition of an important public body and an option to purchase at a definite price within a few days from now, had compelled the Council to act quickly. Mr. Mordey then pointed out the suitability of the building, adding that the lecture theatre, which was rather small, could be made one of the finest halls in London by roofing in the quadrangle. The architect to the Institution had given an excellent report on the general condition of the building. The Council, he said, were unanimous in recommending the purchase of the building, and the contract was ready for signature.

Sir JOSEPH SWAN, Mr. G. WARD (Hon. Secretary for New York), and Mr. E. BARTON (Hon. Secretary for Australia) supported the resolution.

Major CARDEW opposed the passing of the resolution, which he said had been rushed through. He did not think the meeting of some 200 members could be taken as representative, but proposed that a statement should be submitted to members and voting invited. He criticised Mr. Hammond's figures with reference to the probable expenditure in the new building, and expressed dissatisfaction with the building itself.

Mr. MARTIN ROBERTS moved an amendment that the matter be referred back to the Council for further consideration. The building, he said, was too large and altogether unsuitable.

Mr. W. B. ESSON seconded the amendment, pointing out what a serious matter it was to borrow so much money and still expect a deficit at the end of the year. He proposed that the Institution should enlarge the present offices and hire a lecture theatre for the meetings rather than purchase the building under consideration.

Mr. SYDNEY SHARP and Mr. LEON GASTER also spoke.

Mr. ALEX. SIEMENS then rose to oppose the amendment, and pointed out that the Council had already very carefully considered the matter. The new building was none too large; the present building occupied by the Institution of Civil Engineers was not large enough, and the new building would have 20,000 sq. ft. of ground space, which was the same as that of the building under consideration. The enlargement of the lecture theatre was an easy matter, and should be taken on at once. He thought that there would be no difficulty in letting those parts of the building not required by the Institution, and mentioned that the Society of Arts, the Institution of Naval Architects, and the Iron and Steel Institute were all on the look-out for new accommodation.

A few questions were put to Mr. Hammond concerning the Tothill Street site and the lease of the new building, and after these had been answered, the PRESIDENT, in putting the amendment, explained the reason of the rush, and emphasised the fact that if the amendment was passed the building would be irretrievably lost, as the option to purchase expired in a few days.

The amendment was lost, and the original motion was then put to the meeting and carried unanimously.

NEW PUBLICATIONS

"Electric Bells, and all about them." By S. R. Bottone. Seventh edition. (London: Whittaker & Co.) 2s.

"Industrial Electrical Measuring Instruments." By Kenelm Edgcumbe. (London: Archibald Constable & Co.) 8s.

"Field Telephones for Army Use." By Lieut. E. J. Stevens. (London: Crosby, Lockwood & Son.) Price 2s.

New Electric Railway in the Alps.—According to the *Times*, an electric railway from Martigny to Châtelard was opened yesterday. The Paris, Lyons & Mediterranean Railway Co. have also just completed a short line connecting their own system with the above Swiss line. The new line enables tourists to proceed from Fayet, St. Gervais, and Chamonix to Martigny and St. Maurice in Switzerland, returning by Evian, Thonon, and Geneva.

Telegraph Traffic.—Communication to the United States of America and Canada over the cable of the Direct United States Cable Co., which was broken during the recent trawler troubles off the Irish coast, has been restored. The Government of British Guiana have passed a resolution urging his Majesty's Government, in view of repeated failure of telegraphic communication, to support the extension of the British cable system from Bermuda to Barbados, Trinidad, and British Guiana, especially as the suggested establishment of a wireless system between Trinidad and Demerara does not appear to be making any headway.

The Electrical Industry and Port of London Bill.—On Tuesday the Joint Committee of the Houses of Lord and Commons, considering the Port of London Bill, heard evidence from Mr. Alexander Siemens, a director of the firm of Messrs. Siemens Bros. & Co., Ltd. He supported the case put forward by the London Waterside Manufacturers' Association, which is representative of all the waterside manufacturers in the Port of London. Mr. Siemens, who is a member of the Council of the Association, informed the Committee that the rateable value of his premises by the waterside was between £9,000 and £10,000. He was emphatically of opinion that the waterside manufacturers ought to have the certainty of some representation on the Port authority. The latter body ought to have such knowledge as only the manufacturers could give them when fixing rates, &c. Mr. Siemens endorsed evidence that the rateable value of the waterside manufactories represented by the Association was nearly half-a-million, and the industries gave employment to about 70,000 people. Cheap transport was essential to the large manufacturing industries. It was of great importance to the welfare of London that the waterside industries should be represented on the new Port authority. The Association was satisfied with the present condition of affairs. At present they were able to hold their own with foreign competitors because they had a free port. Many materials were bought by waterside manufacturers from merchants in London, who, paying the dues, would therefore get the vote for representation instead of the waterside manufacturers. Their interests ought to be protected against foreign competition. Mr. Siemens emphasised the danger of manufacturers and industry being driven away if heavy and ill-considered charges were imposed.

LONDON ELECTRIC POWER BILLS

London (Westminster & Kensington) Electric Supply Bill.

THURSDAY, JUNE 25TH. (TWENTY-EIGHTH DAY.)

LORD CROMER'S Committee of the House of Lords met on Thursday for the consideration of the London (Westminster & Kensington) Electric Supply Companies' Bill, which provides that the Kensington & Knightsbridge, St. James and Pall Mall, Notting Hill, Westminster and Central Supply Companies may enter into, and carry into effect, agreements providing for the supply of electrical energy in bulk. An agreement has been come to with the Westminster City Council with regard to the compulsory purchase of the bulk supply mains. The Bill provides that any mains laid down under the provisions of this Act outside the area of supply, shall be marked in a distinctive manner so as to distinguish them from other mains or work, and shall not be liable to purchase by the local authority in whose district they are laid, but that they shall be deemed part of the undertaking of the company, and shall be purchasable as if they had been within the district of the local authority entitled to purchase. The Bill also contains the now well-known "standby" clause. A further clause provides that from the passing of the Act the maximum charge for power supply within the areas of the respective companies shall be £6 15s. per annum per kilowatt of maximum demand plus ·33d. per unit. Any consumer requiring more than 20 kw. may be required to enter into a contract for seven years, but no portion of such electrical energy is to be used for lighting purposes. It is further provided in the Bill that the companies may supply railway, tramways, tramroads, canals, navigations, docks, or waterworks, situated partly within and partly without the area of supply, provided such supply shall only be used for the purpose of haulage or traction, or for lighting vehicles of bodies drawn by such haulage or traction. The only other important clause in the Bill relates to the certification of meters, and is for the purpose of removing an anomaly in the general form of provisional order which, as it reads, practically implies that a meter can only be certified *in situ* and not in an electrical inspector's laboratory, such as that of the City of London Electrical Inspector or the London County Council Electrical Inspector. The new clause puts it quite clearly that a meter will be regarded as certified if it is certified by an electrical inspector, and is fixed in a manner approved by the Board of Trade. Presumably, therefore, the practice will continue as at present, viz., that the Board of Trade approves a type of meter and the manner of fixing it, which is published as an official notice in the *London Gazette*, and at any meter certified by an electrical inspector and fixed in that manner will be regarded as a certified meter. The clause also specifies that a meter shall be certified to be a correct meter if it will register within the limits of error that are allowed by the Board of Trade for meters of the class to which the meter in question belongs.

MR. SEYMOUR BUSHE, K.C., who appeared for the promoters together with the Hon. Sidney Holland and Mr. Kennedy, said that a great deal of the purport and object of the Bill was covered by the principle of the decision given on the London Electric Supply Bill the previous day. The Bill enabled certain electric supply companies to link up with one another, and although in view of the previous proceedings it might seem a small matter, yet he could assure the Committee that the promotors attached much importance to it, and felt that it would be a valuable instrument, in their opinion, for the purpose of discharging their duty to the public. All the areas of the companies mentioned were within the districts of one or other of two local authorities—namely, Kensington and Westminster; the Westminster and St. James's Companies were wholly within Westminster; the Notting Hill Company's area was partly in the borough of Kensington, and partly in the City of Westminster, whilst the Kensington and Knightsbridge Company was wholly within Kensington. The principle embodied in the Bill had already been conceded by Parliament, in that the four companies had been permitted to form themselves in two groups of two each which were supplied respectively from generating stations outside the area of supply—namely, at Wood Lane and Marylebone respectively. He also wished to point out that the Board of Trade had for a considerable time been endeavouring to initiate legislation for the purpose of doing away with the restrictions as to association under which electric lighting companies now suffered, and what the Bill asked was to allow the companies named to form themselves into one group for this purpose.

The CHAIRMAN said that, as the schedule of the London Electric Supply Bill included the names of the companies promoting the present Bill, it seemed to him that they therefore got all they wanted in the other Bill.

Mr. BUSHE said that the names of his companies were included in the London Electric Supply Bill against their wish, but they were not promoters of that Bill, and would have no voice in any decision as to whether it will be proceeded with. The promoters of that Bill had on one occasion stated that the Joint Committee formed an important portion of their scheme, and as powers to create a Joint Committee had been struck out of it, it was not inconceivable that the Bill would be dropped. Therefore, the fate of his companies depended upon the action of the other promoters, and placed them in a position which they did not desire. If both Bills were passed, it would not prevent all the companies combining together later on; indeed, it was highly probable that all the companies might come together, but that depended on many things.

Mr. J. H. HORDERN (Manager of the Westminster Electric Supply Corporation) was called in support of the Bill, and Mr. Freeman, K.C., for the London County Council, cross-examined to the effect that the Bill only gave all that was given in the London Electric Supply Bill.

Mr. HORDERN agreed that this might be so, but pointed out that his shareholders had not sanctioned the promotion of that Bill, and, therefore, they had no voice in the policy of it. It was conceivable that the other companies would strike the names of the present promoters out of that Bill, and, further, they did not wish to be involved in the fate of the other Bill, whatever that might be.

Mr. FREEMAN, addressing the Committee on behalf of the London County Council, urged that it was entirely contrary to Parliamentary precedence to pass two Bills giving identically the same powers, although he had no objection to the Bill on its merits.

After deliberation the Chairman announced that the Committee were of opinion that the Bill might proceed on the understanding that the clauses in it must be identical with the clauses of the London Electric Supply Bill when these came to be considered.

The Committee sat during the week to consider clauses of this Bill, together with the London and District Electric Power ("Parshall-Hammond") Bill and the London Electric Supply ("Eight-Company") Bill.

Tramway Authorities and Mutual Insurance.—A conference of municipal and other tramway authorities was held in London on Friday last, says the *Yorkshire Post*, to consider proposals put forward by the Corporation of Halifax for establishing a mutual scheme of insurance against "third party" risks. The matter was fully discussed, and a committee was appointed to formulate a scheme, which will be submitted to the authorities represented at the next meeting. The committee was constituted as follows:—Councillors C. F. Spencer and D. Hanson, Halifax Corporation; Mr. Geo. Troudman, Birkenhead Corporation; the Hon. Arthur Stanley, Lancashire United Tramways; Councillor C. E. Perry, Exeter Corporation; Mr. E. Hatton, Newcastle Corporation; Alderman Winter, Rotherham Corporation; Mr. F. Schofield, Leyton Urban District Council; Mr. H. E. Blain, West Ham; Mr. Robert Hilton, Swindon Corporation; Mr. Cecil Barber, Bournemouth Corporation; and Alderman Lindsey, Salford Corporation. Mr. H. Ashling, Deputy Town Clerk of Halifax, was appointed secretary to the conference.

A NEW AUTOMATIC TRANSFORMER SWITCH

AN automatic switch for use in connection with small house transformers for metal filament lamps was described on page 789 of our issue of May 21st, 1908. Mr. W. J. Davy, the inventor of the particular switch there described, has given further attention to the matter, and has developed an automatic switch which is extremely simple in its operation, and which is particularly adapted for use with an auto-transformer. The operation of the switch can be best understood by referring to Fig. 1, which gives a diagram of the connections employed. In this diagram, *A* is the low-pressure section of the auto-transformer, which transforms down from the mains pressure of 250 volts to the lighting pressure of 25 volts; *S* is the single-pole switch which connects the transformer to the mains; and *C* and *D* are magnetising coils wound in opposite directions on the core of an electro-magnet which, when magnetised, closes the switch *S*. Under ordinary conditions the switch *S* is open, as shown, and no current flows in any of the circuits. If, however, one of the lamps (*L*) is switched on, a small current flows through the coil *C*, the lamp, and the high-pressure portion (*B*) of the auto-transformer. This current, though not sufficient to cause the filament of the lamp to become incandescent, is sufficient to magnetise the electro-magnet mentioned above. The switch *S* is therefore closed, the transformer connected to the mains, and the lamp lit. Immediately the transformer is connected, a larger current flows through the magnetising coil *C*, and as the load increased, the iron loss and the inductive drop due to this electro-magnet would increase to a serious extent, were it not for the neutralising action of the coil *D*, which, as stated before, is wound on the core in an opposite sense. The coil *D* only partly neutralises the effect of coil *C*, and consequently coil *C* will always have a slight magnetising effect on the core of the electromagnet, and the switch *S* will remain closed so long as lamps are switched on at *L*. When the last lamp is switched off, the switch *S* is opened, as the magnetising action of the no-load current of the transformer, flowing through the coil *D*, is not strong enough to keep the switch closed. Thus directly the last lamp is switched off the transformer is switched off the mains, and no-load losses, during the periods when the lamps are not in use, do not occur. Another source of continual loss under ordinary conditions is the shunt current of the meter. In Fig. 1, *E* represents the series coil, and *F* the shunt coil of the meter, and the latter is connected so that when the main switch *S* is opened, the meter shunt circuit is broken, and thus no continual loss occurs. The use of such a switch will save, therefore, not only the transformer no-load losses, but the meter shunt losses during periods of inactivity as well.

The construction of the combined transformer and switch is illustrated in Figs. 2, 3, and 4. In Figs. 2 and 3, *H* is the core

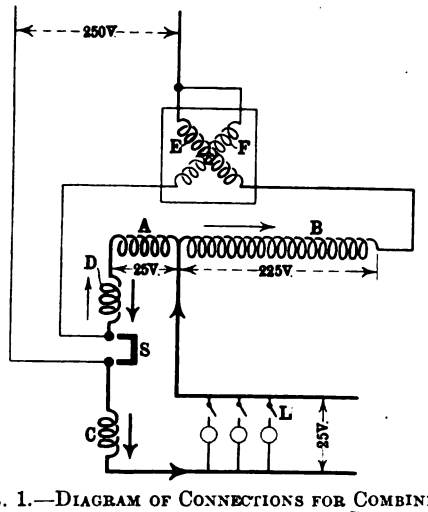

FIG. 1.—DIAGRAM OF CONNECTIONS FOR COMBINED AUTO-TRANSFORMER AND AUTOMATIC SWITCH.

of the auto-transformer, and *G* is the winding. The armature *D*, attached to the lever *B*, is shown drawn down into the gap of the electro-magnet *A*. The two magnetising coils are shown diagrammatically at *L* and *K* in Fig. 3. The lever *B* is pivoted at *C*, and supports at one end the weight *W*, and at the other end the connecting link *E*, which, with the two mercury cups (*F*), forms the main switch.

A small movement of the armature *D* gives a large movement of the switch link *E*. The weight *W* must be so adjusted that when one lamp is switched on, the pull on the armature *D* is sufficient to draw it down, and thus close the mercury switch. The shape of the armature and gap of the electromagnet can be seen in Fig. 4. Although this combined transformer and switch is not yet on the market, two or three are already installed, and are proving very satisfactory. The transformer can be installed in a consumer's house without any alteration whatever to the wiring, and the same candle-power lamps as

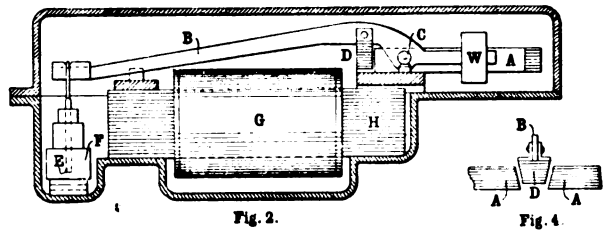

FIG. 2. FIG. 4.

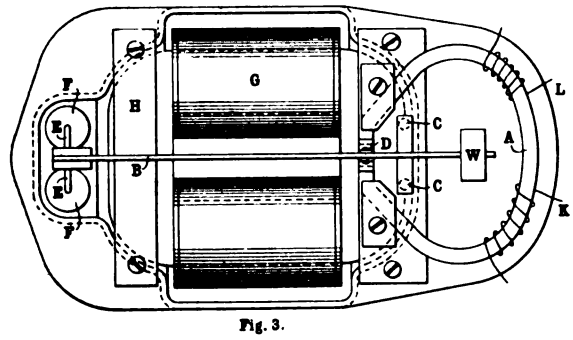

FIG. 3.

ELEVATION AND PLAN OF COMBINED TRANSFORMER AND AUTOMATIC SWITCH.

hitherto employed may be used. Thus the 10 and 16 c.p. carbon filament lamps usually employed in private houses may be replaced by 25-volt metal filament lamps of the same candle-power; whereas with high pressures, the metal filament lamps would have to be 32 to 50-c.p. lamps. The filaments of the low pressure lamps are also much stronger than the high pressure metal filaments, and the low-pressure lamps may consequently be burnt safely at any angle.

Franco-British Exhibition.—A slight inaccuracy which appeared in our description of the stand of the Société Gramme in the French section of the Machinery Hall at the Franco-British Exhibition has been pointed out to us by Messrs. T. L. Scott & Co., Ltd., who are the London agents for this firm. The exhibit which we specially mentioned of a complete generating set, comprising gas suction plant, engine, and dynamo, is not an exhibit of the Société Gramme, but is shown by E. Bardot, of Paris. The set in the exhibition is specially constructed for running on wood charcoal.

Auto-mixte Railway Cars for the L.B. & S.C.R.—Two petrol-electric railway cars are under construction for the London, Brighton, and South Coast Railway, embodying what is known as the Auto-mixte, or Pieper system of control, in which an ordinary petrol engine is coupled to a shunt-wound machine, which can act either as a generator or a motor, according to circumstances, as it is also connected through a clutch and suitable reduction gear to the rear wheels. When the car is at rest, or when the full power of the engine is not needed for propulsion, the dynamo is employed to charge a battery, but when extra torque is required for starting or hill-climbing, the battery drives the dynamo as a motor to assist the engine. According to the *Railway Times*, the trial motor-cars which will shortly be running on the Brighton railway are being fitted with petrol engines of 120 h.p. capacity by the Daimler Co. The dynamo-electric machine is rated at 50 h.p. as a motor. There are 48 accumulator cells. The cells are arranged in four sets, twelve cells per set. There are four stops on the controller: (1) Four sets of cells in parallel across the armature, and four field coils in parallel; (2) the cells are arranged in two sets, two in series, the two sets in parallel; the field coils being arranged in the same way; (3) the sets are arranged in series with a rheostat in series with the armature, the field coils being now in series across all the cells in series; (4) the cells in full series across the armature, the field coils also in full series. By this means a very large starting torque is obtained—the current taken from the cells when the car is fully loaded being about 1,000 amperes on the first stop, and about 600 amperes on the second. A high acceleration will thus be obtained.

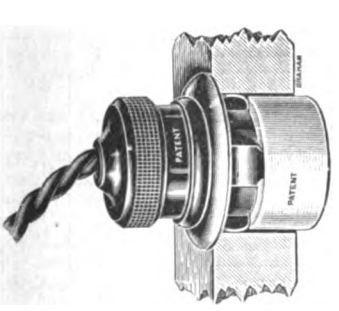
CENSUS OF PRODUCTION ACT, 1906

ACCORDING to this Act, a census of production in the United Kingdom is to be taken this year, and subsequently at intervals to be determined by the Board of Trade. The taking of the census is in the hands of the Board of Trade, which is to issue a report on the matter. Forms are being sent out to manufacturers, mine-owners, builders, and other engineering concerns, and these are to be filled in and returned to the Board of Trade, Census of Production Office, at 68 Victoria Street, S.W. We have received a copy of the form which is being sent out to manufacturers and others in the electrical engineering trades. This form has been prepared after consultation with the Cable Makers' Association, and with important firms representing the different branches of the electrical industry. All information given in fulfilment of the obligations imposed by the "Census of Production Act" will be treated as strictly confidential. The main object of the Act is to ascertain the total production of the United Kingdom, and the information supplied will, therefore, be used solely in the compilation of general statistical results, and no particulars with respect to any individual establishment or firm will be in any way disclosed. Any person improperly disclosing such information or publishing information so disclosed is liable to imprisonment for two years, with or without hard labour, or to a fine. The form is divided into two parts, (*a*) compulsory information, and (*b*) voluntary information. The first part contains the following questions: (1) nature of trade or business, (2) year of return, (3) output in year of return. The output stated in answer to question (3) should be the total value of the goods made in the year of return, irrespective of whether part of these remain in stock, or whether all are sold. Factored goods, which are simply re-sold without any further work being done on them, are not to be included as output, but goods made from assembled parts are to be returned at their value as finished products. The goods manufactured must be put under one or more of the headings provided in the schedule, and figures for "Contract Work in the United Kingdom," "Repairs and Maintenance Work for Customers," and "Constructional and Repair Work on own Buildings and Plant," must also be included. The object of question (4) is to determine the net value of the production in the United Kingdom in the year of return. For this purpose, the estimated aggregate cost of purchased materials and stores used in the year of return must be given. The estimated amount payable to other firms for work given out to them must be given in answer to question (5), in order to prevent duplication in the case of work given out to other firms. The number of persons employed on four defined days is the subject of question (6). These are divided into two classes under the headings of wage-earners and salaried persons. The number of calendar days on which the establishment was open for production in the year of return, and the average percentage of wage-earners at work on Sundays are required in answer to question (7). The last question in the compulsory part relates to the capacity of steam, gas, or other power plant in the works, and in the case of an electric power supply from without, the amount of electricity supplied in the year of return must be stated. In the second part of the form, the following questions are put under the heading of voluntary information: (1) The estimated value of the selling output in the year 1906. (2) quantity of copper used in the year of return in the manufacture of cables, and (3) the fuel consumed in the year of return.

A NEW TYPE OF WALL CONNECTION

IN a description of the electrical installation at the new Public Offices at Whitehall, given on page 917 of our issue of June 18th, mention was made of a new type of wall-plug socket which is not screwed on to a wood block sunk in the

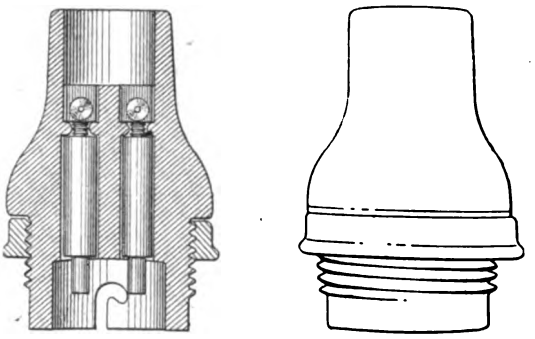


"CLINCHER" WALL SOCKET AND PLUG.

wall, but which is either sprung into a brass ring attached to a block or is simply sprung into a hole bored in the skirting board. We have since received some further particulars of this type of wall connection from the makers, Messrs. A. P. Lundberg & Sons, of 477 Liverpool Road, Islington. The fitting in question is known as the "Clincher" connection (Patent No. 11,430 of 1906), and is made in two sizes: the "Dot," or 2·5 amp. size, and the "Universal," or 5 amp. size. The former is illustrated in the figure, which shows the socket sprung into a hole bored into a wooden floor or skirting board. In order to keep the diameter down, the usual type of porcelain centre has been retained. The use of fixing screws is obviated, and a very neat appearance is produced. This fitting is intended for use in floors, skirting boards, furniture, panelling, desks, &c., and lends itself well to any special finishing when it is required to match existing fittings. The polished brass ring is provided with four spring arms formed out of the same piece of metal, as the figure shows. A hole is bored in the skirting board just large enough to take the porcelain centre, and after wiring up, all that is necessary to fix the socket is to force it into position, when the spring arms grip it securely.

A NEW PORCELAIN LAMPHOLDER

THE accompanying illustration represents a new form of lampholder which is being introduced, under the Knowles patents, by Messrs. L. E. Wilson & Co., of Manchester, which is specially suitable for use in the presence of acid fumes, and



KNOWLES' PATENT PORCELAIN LAMP-HOLDER.

it is incorrodible, being constructed entirely of a single piece of porcelain without any joint through which fumes or vapours could gain access to the interior of the holder. The plungers, with their containing tubes, are cut out of solid brass rod, accurately turned and bored, and are tapped to receive the adaptors or sweating terminals to which the conducting wires are soldered. The sweating terminals consist of square-headed brass screws having taper necks. The screwed portions are one-eighth inch in diameter, and are pointed at the ends. The heads of the screws are bored out to receive the conducting wires which are soldered in. Small countersunk holes are drilled in the sides of the square heads to facilitate the soldering. The sealing chamber at the upper end of the holder is filled with compound which effectually protects the terminals from moisture or chemical action. After the lamp is inserted, the joint round the neck may be made good by a lapping of asbestos yarn held in place by prepared tape.

It will readily be seen that the construction gives excellent insulation, not only between the plungers, but also at the lamp opening, as the usual brass tube is entirely superseded by porcelain. The usual bayonet slots are done away with, and grooves are moulded in the thickness of the porcelain to receive the pins of the lamp socket, thus hermetically sealing the usual openings by which fumes would otherwise penetrate to the interior of the holder. The plungers, which are of substantial construction, are renewable, and may be exchanged in a few seconds without disturbing the sweating terminals by merely unscrewing them with a forked screwdriver, and screwing new ones in their places.

Fire at the Savoy Theatre.—According to the *Times*, a slight fire broke out at the Savoy Theatre shortly before midnight on Saturday last. The outbreak, which occurred in the electrician's room, was detected by the fireman attached to the theatre, and in a short time the fire was put out. The switch-gear in the electrician's room was practically destroyed, and the room itself was seriously damaged. No other part of the building was affected, however, and the working of the theatre will not be interfered with in any way.

X-ray Dermatitis.—Mr. Hall Edwards, of Birmingham, who was recently granted a Civil List pension of £120 per annum in recognition of his services in the development of medical radiography, has been obliged to undergo a further operation. The operation, which was performed on Sunday last, involved the removal of the fingers of the right hand. The left arm was amputated below the elbow in February last. Mr. Hall Edwards has for some time been engaged on a work on Dermatitis, which is now nearly complete.

BRITISH ELECTRIC TRACTION CO.'S MEETING

AT the annual meeting on Thursday, the report and accounts given in our last issue were adopted. Sir Charles Rivers Wilson, the chairman of the company, who presided, said that, in the directors' opinion, the fall in the market value of the company's shares and debentures during the year was much greater than the circumstances of the company called for, and an unwarranted impression seemed to prevail that the general position of the company was not satisfactory. The subscribed share and debenture capital of the company was £4,949,969, the amount due to creditors was only £12,570, and the debenture interest accrued was £46,623, so that, apart from the reserve for depreciation and the balance at net revenue account, the total on the debit side of the balance-sheet was £5,009,165. To meet this there were assets amounting to £5,658,653, and of this large amount the intangible items, like expenditure on Acts of Parliament and other rights and powers which might or might not be realised, and goodwill represented only £18,528, so that there was a surplus of assets of about £631,000, and the important question for the shareholders was whether the depreciation of the securities held by the company was greater or less than the surplus. The difficulties of making an accurate valuation of the numerous investments and undertakings controlled by the company were so great that the directors were unable to attempt it. There could, however, be no doubt that the estimated depreciation of the company's debentures and shares had been exaggerated. The net profit amounted to £203,194, and after deducting debenture interest and bringing forward the balance from last year, there remained £118,824. The directors had had a good deal of discussion as to how this balance should be applied, and had decided that £35,000 should be added to the general reserve, raising this to £602,420, that £35,000 should be carried forward, and £48,431 applied to the payment of a dividend on the preference shares equal to 3 per cent. for the year. They regretted the dividend was not larger, but the important thing was to reassure the shareholders that the directors were not paying dividends at the expense of the future stability of the company. They held a quarter of a million consols, £50,000 in cash, and close on £400,000 in debenture stocks of electrical companies, besides several millions of other securities. Very few companies in England could show an equally strong position.

The subsidiary undertakings were well established, and were not over-capitalised. In the course of a few remarks upon the legislative and municipal conditions of Great Britain in their relation to the electrical industry, Sir Charles Rivers Wilson stated that electrical enterprises in this country had been greatly influenced by political considerations. Electric traction was not generally adopted in this country for nearly ten years after electrical tramways had been demonstrated to be sound commercial undertakings in America and on the Continent, because it was impossible to embark capital under the terms of the original Tramways Act. The work of the British Electric Traction Co. had aroused the jealousy of local authorities, who were urged by an agitation in favour of municipal socialism to enter upon the business themselves, and where they could not do business themselves, they thwarted and harassed private enterprise. Parliament had yielded to the clamour in favour of municipal trading, and added to this was the constant demand by the public for increased facilities and reduced fares. Hence the difficulty of making profits. At the same time he emphasised the point that the company was in a position to undertake new business, and had ample resources for initiating new enterprises. Mr. H. O. Arnold-Forster, M.P., seconded the resolution for the adoption of the report and accounts. Sir Charles Rivers Wilson and Sir Charles Fremantle were re-elected directors.

The Electrical Standardising, Testing, and Training Institution.—An examination for a "Maxwell" entrance scholarship, value one hundred guineas, will be held at Faraday House on Wednesday, July 22nd, and the following day. Notice of intention to compete should reach Mr. H. Foulds, secretary, Faraday House, 62 Southampton Row, not later than July 12th. Further particulars may be obtained from Mr. Foulds on application.

Running Powers on Eccles Corporation Tramway Lines.—We learn from the *Manchester Guardian* that on Thursday last, in the Chancery Division of the High Court, Mr. Hughes, K.C., for the Eccles Corporation, moved for an injunction restraining the South Lancashire Tramways Company from running trams over lines belonging to the Corporation. Counsel said there was an arrangement between the Eccles Corporation and the Salford Corporation, under which the latter worked the tramway service in Eccles. The present dispute arose over a claim by the South Lancashire Tramways Company, under a licence from the Salford Corporation, to run their trams over a portion of the lines without the consent of the Eccles Corporation, whose case was that the Salford Corporation were not entitled to sublet the lines. Mr. Justice Eady said he did not see how he could determine the construction of the agreements on a motion and in the absence of the Salford Corporation, and he ordered that the motion should stand over until the trial of the action, but granted leave to appeal against that decision.

CATALOGUES AND PAMPHLETS RECEIVED

ACCUMULATORS.—A pamphlet from the Hart Accumulator Co., Ltd., of Stratford, London, gives particulars of batteries for use in house and other installations where 25-volt metal filament lamps are employed. The listed sizes of batteries, each consisting of 13 cells, range from 8 to 960 ampere-hour capacity on a 10-hour discharge rate.

ALUMINIUM.—We have received two pamphlets from the British Aluminium Company, Ltd., of 109 Queen Victoria Street, E.C. One of these contains a comparison between copper and aluminium for electrical conductors, and the other is a reprint of the articles on "Aluminium: Its Present and Future Uses," which appeared recently in the *Times*. A chapter in this booklet deals with aluminium as a substitute for copper for electrical purposes.

AUTO-TRANSFORMERS.—A pamphlet from the British Electric Transformer Co., of Hayes, Middlesex, gives particulars of two types of the Berry transformers for use with metal filament lamps. Each type can be obtained as a two-winding transformer, an auto-transformer, or as a balancing auto-transformer; the differences between the two types illustrated in the pamphlet being in the building up and arrangement of the core.

BOILER MOUNTINGS.—A very handsomely executed catalogue of various specialities in the way of boiler fittings has been issued by Messrs. James Baldwin & Co., of Keighley. Attention is particularly called to the "Betall" stop valve, with simply arranged renewable valve and seating, Baldwin patent combination safety valve of high steam and low water, a water hammer safety spring stop valve, and other boiler mountings.

ELECTRIC LIGHTING, HEATING, AND COOKING.—The new catalogue issued by Simplex Conduits, Ltd., covers a very large range of lighting, heating, and cooking appliances, including a number of novelties recently introduced, although the extent of the operations of the firm are, of course, considerably wider than can be comprised in a single list. Attention should be particularly called to the list of prices of V.I.R. wires and cables of qualities similar to "Association" and "Non-Association" classes of material, and a specially low-priced "Competition" quality to fill the demand for a cheap but really good cable. A large number of patterns of installation switches and other accessories, carbon and metal filament lamps are listed. A special feature of the catalogue is the section devoted to heating and cooking apparatus. This includes heaters of the radiation and convection types, and a very complete series of kettles, hot-water jugs, flat irons, and other domestic appliances. The fittings section is admirably printed, and contains many new artistic designs. The final pages deal with Simplex electric fans.

ELECTRICAL SUPPLIES.—We have received a collection of price sheets from the E.M.F. Manufacturing Co., dealing with arc-lamp carbons, a new type of automatic sign switch, lamp holders, and series adaptors, special reflectors for metal filament lamps, high and low voltage metal filament lamps, dry cells, fans, and small power motors.

IGNITION ACCESSORIES.—An illustrated price-sheet from H. Miller, Ltd., of Hazelnouch (France) deals with several patterns of pocket and other voltmeters for ignition batteries, and sparking plugs, with and without external spark-gaps.

MARYLEBONE ELECTRICITY SUPPLY.—An excellently printed souvenir of the St. Marylebone Electricity Supply Undertaking has been sent us. This contains a well-illustrated description of the generating station, mains, and sub-stations, and also some information relating to the recent development of the undertaking. The rates of supply, publicity, and canvassing work, and the administration are also dealt with. A series of attractive leaflets, dealing with metal filament lamps, electric heating, and cooking apparatus, flame arc lighting, electric power, and electric signs, have also been published by the Electricity Department of the Borough.

TELEGRAPH, TELEPHONE, AND TRANSMISSION LINE POLES.—We have received from Richard Wade, Sons & Co., Ltd., of Hull, a revised copy of their catalogue of wooden poles containing the results of tests on poles for all purposes. This has been considerably enlarged, and should be in the hands of all engineers interested in overhead construction. Excellent photographs of overhead work carried out for various companies are included, together with full particulars of the usual construction adopted. Messrs. Wade are sending this book free of charge to regular customers only, the price per copy to others being 10s. 6d.

The Electrical Contractors' Association (Incorporated).—At the annual meeting of this association, Mr. E. C. Wallis, of Leeds, was elected president for the ensuing year. The outgoing president is Mr. A. Rashleigh Phipps. During the past year nearly 100 new firms have applied for, and have been elected, to membership. New branches have been formed in Dundee, Aberdeen, Leicester, Birmingham, and Cheltenham. The financial position has been considerably improved, and the Law and Parliamentary Committee have been successful in getting clauses amended in several Corporation Bills. The Central Board will shortly consider the question of the registration and examination of workmen, and the formation of other branches of the association throughout the kingdom.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published June 25th, 1908

A full list of these was published in our last issue. The following are abstracts of the more important specifications.

Names in brackets indicate communicators of inventions from abroad.

1907 Patents

10,072, **Series-parallel Control.** BRITISH THOMSON-HOUSTON Co. (*General Electric Co.*). A method of altering the connections of series-wound motors from series to parallel, without opening the motor-circuit, and without unbalancing the load on the two motors. The motors are provided with divided field windings as sometimes employed for securing an intermediate speed. The halves of each motor field winding are connected in parallel in the series connection. To change to parallel connection, each motor is shunted by a resistance; a half-field winding of each motor is then disconnected, and the series connection broken, leaving each motor connected in series with a resistance to the source of power. The disconnected half-fields are then placed as shunts across the resistances, which are afterwards cut out, leaving the two motors in parallel, and both half-fields of each motor in series with their respective motors. Five claims, twenty figures.

20,119, **Wireless Telegraph Transmitter.** G. MARCONI AND MARCONI'S WIRELESS TELEGRAPH Co. According to this invention, each of the plates of the condenser in the oscillating circuit is respectively connected to one of a pair of revolving discs of metal, situated at such a distance apart as not to allow a discharge to pass when the condenser is charged, and the gap between the discs is partially bridged at regular intervals by pieces of metal which may be pegs or projections attached to a third disc, which rotates between the two discs above mentioned. The two latter discs are rotated at a sufficient speed to prevent pitting or burning of their surfaces. The third disc is rotated at the speed necessary to obtain the desired frequency of discharge. The apparatus is capable of emitting oscillations in regular groups so as to produce a readily recognisable note in a telephonic receiver, which makes it easy to differentiate between signals emanating from the transmitting stations, and noises caused by atmospheric electrical disturbances. Four claims, one figure. (Sets have been installed at Clifden and Glace Bay Wireless Stations—see ELECTRICAL ENGINEERING, Vol. III., p. 430.)

24,753, **Connections for Aluminium Electrolytic Rectifier.** SIEMENS BROTHERS & Co. (*Siemens & Halske Aktien-gesellschaft.*). This invention consists in the use of two cells or two groups of cells connected oppositely to one another. One cell is connected in the main circuit, and the other is connected as a shunt across the load. The first cell permits currents in the positive direction to pass through it and the load; the second cell, being connected in the opposite way, does not let current pass through it, but is charged up, acting as a condenser, and discharges through the load during the negative half-wave period when there would be otherwise no current flowing through the load. One claim, one figure.

27,379, **Wireless Telephony.** AMALGAMATED RADIO-TELEGRAPH Co. (*G. Siebt*). To effect wireless telephony, changes in either the amplitude or the periodicity of the electrical oscillations, corresponding to the air vibrations generated by speaking, must be produced. For this purpose a microphone is inserted directly into the antenna or into a circuit coupled with the antenna. For the maximum effect, the damping action of the microphone resistance should be equal to the damping action of the other resistances in the antenna, *i.e.*, these resistances should be equal. If this is not the case, a capacity and an inductance in series should be placed in parallel with the microphone, when this has too low a resistance; or, if the microphone resistance is too high, a capacity or an inductance should be connected in parallel with it. Three claims.

1908 Patents

5,610, **Supports for Metal Filaments.** ALLGEMEINE ELEKTRICITÄTS-GESELLSCHAFT. An improved anchor for keeping suspended-stirrup-form filaments in tension without interfering with the linear expansion or contraction of the filament. The anchor has a stationary and a movable member, the former being sealed into the glass pedestal or the bulb. The filament passes through the movable member, which is so hinged to the fixed member that linear but not lateral movement of the filament is possible. There is no spring; the weight of the movable part holds the filament straight, the weight being proportioned to the diameter of the filament. Two claims, five figures.

6,050, **Process for Hardening Tantalum.** SIEMENS & HALSKE AKTIEN-GESELLSCHAFT. As a hardening agent, partially oxidised tantalum can be used. This is first tested as to its hardening power by adding it in different proportions to pure soft tantalum, melting the mixture and then testing the hardness, capacity for being worked, brittleness and like properties of each sample. It is then easy to produce any desired degree of hardening by adding, before fusion, a certain amount of the hardening agent to the soft tantalum to be hardened. The proportion of oxygen in the hardening agent determines the degree of hardening, but there is no known process for determining the amount of oxygen in partially oxidised tantalum. One claim.

7,910, **Thermo-electric Pyrometers.** SIEMENS BROTHERS & Co. (*Siemens & Halske Aktien-gesellschaft*). When pyrometers are used continuously for measuring the temperature of a bath of molten metal or metal salt, the wires are apt to be quickly destroyed by vapour from the molten mass, owing to the permeability of the casing enclosing them. To avoid this, the wires, which are embedded in porcelain or corundum, are surrounded with a metal tube, and this tube is provided with an electrolytically deposited coating of nickel or other suitable metal. To protect this coating from the action of the molten metal, a further casing, preferably of iron, is provided. A renewable metal sleeve should be fixed to the casing at the part which extends through the surface of the bath. This resists the action of the slag for a long time, and can be renewed when destroyed. Two claims, one figure. (Further information relating to pyrometers will be found in ELECTRICAL ENGINEERING, Vol. III., p. 778.)

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.

Summaries of the more important of these patents will appear in our next issue.

1907 Patents

5,314, BLOXAM (*Soc. Generale per la Cianamide*). Manufacture of nitrogen compounds from carbides.
12,937, FELTEN & GUILLEAME LAHMEYERWERKE ACT.-GES. Compensated alternate current series motors.
13,129, GROB. Lighting and heating of vehicles.
13,147, BROCKIE. Enclosed arc lamps.
13,190, HARRISON & HIRST. Electrodes for arc lamps.
13,432, SCHATTNER. Fusible cut-outs.
13,712, PARSONS & LAW. Regulation of dynamos.
13,821, JENTZSCH. Coin-controlled telephones.
14,567, ECKSTEIN, HEAP & MELLIS. Switches.
15,366, AMBERTON & SCHATTNER. Electric regulators.
15,367, BRITISH THOMSON-HOUSTON Co. (*General Electric Co.*). Manufacture of metal filaments.
17,300, BUCKTON. Combined plug, socket, and switch.
18,044, FELTEN & GUILLEAUME LAHMEYERWERKE AKT.-GES. Single-phase shunt machines.
18,187, BAILEY. Means for signalling the approach of tramcars at cross roads.
18,936, LECOEUR. Manufacture of cellulose filaments.
20,824, IRWIN. Electric oscillographs.
26,084, MEYERLING. Continuous-current meter.
26,973, ANDERSON. Sparking plugs.
28,220, THOMAS. Starting means for vapour-electric devices.

1908 Patents

207, KUZEL. Process for the production of alloys.
325, SANDERS & GREENBERG. Induction coils.
4,286, TARDIEU. Suspension device for microphones.
4,433, SIEMENS-SCHUCKERT WERKE GES. Starting and working of three-phase motors from a single-phase supply.
4,692, SIEMENS-SCHUCKERT WERKE GES. Brush-holders.
4,831, LEVY. Automatic tramway and railway switches.
5,698, SIEMENS BROS. & Co. (*Siemens & Halske Akt.-Ges.*). Electrical block apparatus for railways.
5,783, HOWELL. Incandescent electric lamps.
6,757, VON PINDTERSHOFEN. Electric cables.
7,125, Firm of ROBERT BOSCH. Shuttle armatures.
9,563, BLOXAM (*Siemens & Halske Akt.-Ges.*). Manufacture of glass.
9,977, ALLGEMEINE ELEKTRICITÄTS-GES. Electrical power transmission systems.

Complete Specifications open to Public Inspection before Acceptance.

1908 Patents

3,366, DE LA NEZIÈRE. Vulcanising apparatus.
4,461, MICHAUD & DELASSON. Manufacture of filaments.
11,064, TIMAR & VON DREGER. Starting switches.
11,524, SIEMENS & HALSKE AKT.-GES. Manufacture of metal filaments free from carbon.
11,603, SIEMENS & HALSKE AKT.-GES. Manufacture of tungsten filaments.
12,265, KOCH. Systems of signalling.

SUMMARY

"J. W. B." and "Chief Assistant" contribute letters on the desirability of having an Assistant Engineers' I.M.E.A. Convention, which was suggested in our Editorial Notes last week. (Pages 48 and 70.)

A company has been formed for supplying London with a service of electric taximeter cabs. The first 100 cabs will be housed at the garage of the Electromobile Co. This company is also supplying the first 100 cabs, and has entered into a contract with the new company for the running and general upkeep of the cabs. The electrical equipment of the cabs is the same as that in use on the well-known private cars of the Electromobile Co. (Page 49.)

The Convention of the Incorporated Municipal Electrical Association was resumed on Thursday at Nottingham. Mr. S. L. Pearce, City Electrical Engineer, was elected President for the coming year, and Manchester, of which city Mr. Pearce is the Electrical Engineer, was selected as the meeting place for the next Convention. Mr. W. W. Lackie (Glasgow) now becomes senior Vice-President in place of Mr. Pearce, and Mr. J. Christie (Brighton) was chosen as junior Vice-President. We publish a list of the other members of Council. The Council's report was next discussed, and considerable attention was devoted to the question of local authorities' liability under the Workmen's Compensation Act, and "third party" insurance. The refusal of the Local Government Board to sanction delegates' expenses being paid was criticised as usual, and there was also a debate, initiated by the Scotch members, on the action of a railway company in granting wayleaves to power companies. A resolution was passed instructing the Council of the Association to take action in this matter. On Thursday afternoon two Papers on questions of the design and operation of generating stations were read and discussed. Mr. H. Richardson, Chief Electrical Engineer, Dundee, referred to the new station he had recently designed (of which we publish drawings), and discussed various matters relating to the construction and working of generating stations. He favoured reinforced concrete piles for foundations, and steel skeleton buildings with either light brickwork filling, or corrugated iron walls and roofs, and he compared brick, concrete, and steel chimneys to the disadvantage of the last-named. The Paper also initiated a discussion upon the use of gas engines in electricity works, and Mr. S. L. Pearce's contribution to this showed that he had been considerably impressed with the possibility of employing gas engines in conjunction with steam turbines in the manner advocated by Mr. Leonard Andrews (who also spoke). Boiler house

Digitized by Google

construction and practice came in for a share in the debate, and incidentally also it appeared that one of the Local Government Board inspectors had suggested that the galvanised iron end of an engine room should be paid for out of revenue. Mr. C. M. SHAW, Chief Electrical Engineer, Worcester, who read the second Paper, described how this undertaking had been reconstructed with a view to benefiting by the water power which had hitherto been something of a white elephant. On Friday the proceedings were opened with a Paper by Mr. A. M. TAYLOR (Assistant Electrical Engineer, Birmingham), suggesting the employment of accumulators on a far bolder scale than hitherto. He proposed, for instance, that a works with a maximum load of 10,000 kw. should only have a plant capacity of 6,000 kw. (including spares) in generators, and that the peak should be taken entirely by batteries. The author brought a formidable array of curves and tables to show that this policy would be economical, but his premises were attacked by the central station engineers who took part in the discussion. The last Paper was on the testing and standardising department of an electricity works, and was presented by Mr. H. A. RATCLIFF, who is in charge of this department at Manchester. The Paper covered the whole subject in considerable detail, and dealt with meter testing, photometry, mains testing, fault localisation, &c. It was followed by a short discussion. (Pages 50-68 and 81-85.)

LORD CROMER'S Committee has now concluded its inquiry into the London Electric Power Bills, and all three Bills have been reported to the House of Lords for third reading. Among the alterations in the clauses of the London and District Electric Power Bill is the reduction of the amount which a power user may use for lighting purposes, from 20 per cent. to 15 per cent., which the Committee desired in view of the arguments put before it that the introduction of metal filament lamps had an influence upon this question. The renewals fund is also to be made obligatory to the extent of half per cent. of the capital expenditure after the company has paid 5 per cent. dividend. Clauses have been inserted providing for the subscription of £600,000 capital within one year and a substantial commencement of the works within two years, whilst in deference to the wishes of the Coal Smoke Abatement Society, a very definite "nuisance" clause, mentioning specifically "reasonably preventable evolution of oxides of sulphur," has been put upon the company. (Page 69.)

SOME notes are given on new patterns of loud-speaking telephones and accessories. (Page 70.)

A SHORT article describes a form of totally enclosed motor with forced ventilation, which has been developed for use under special circumstances. (Page 70.)

REPORTS dealing with depreciation and obsolescence of the plant of the Coventry Corporation electricity undertaking have been issued by Mr. J. A. JECKELL (Manager and Engineer) and Mr. E. T. PEIRSON (Professional Auditor). (Page 71.)

A LARGE party was entertained at lunch on Tuesday in the buildings being erected for the Manchester Electrical Exhibition, when an opportunity was given of seeing the excellent progress that has been made. (Page 73.)

THE accounts of the Sheffield Corporation for the past year show a profit of £4,796 after providing for interest and sinking fund charges. In a report upon the financial and commercial position of the electrical undertaking, a special sub-committee states that over 50 per cent. of the price paid to the old company for the underaking is now unrepresented by tangible assets. Sir Alexander Kennedy has also reported in connection with the advisability of concentrating all generation at Neepsend.—The Worcester Corporation electricity accounts show that considerable economies have been effected by the reconstruction of the system. —The National Telephone Co. have given notice of a revision of rates in Swansea on the expiration of the present contracts.—A profit of £6,254 for the past year is shown in the accounts of the Burnley Electricity Department.—A deputation from Dundee has visited the Continent to inspect examples of the trackless trolley system. It is stated that they will urge its adoption on the outskirts of Dundee.—It is reported that Messrs. Beardmore are negotiating with a view to the establishment of electrical works in Johannesburg in competition with the Victoria Falls Power Co.— Legal proceedings will probably be taken by the Stepney Borough Council against the City of London Electric Lighting Co., in respect of the supply now given by the latter at the Tower of London.—The accounts of the St. Pancras Electricity Department for the past year show a profit of £9,454, after meeting working expenses, interest, and sinking fund charges. —An inquiry is taking place by the Board of Trade into an application by the Hove Corporation for a reduction of the prices now charged by the Hove Electric Lighting Co. The right of the Corporation to institute this inquiry was given under an agreement in 1892. (Pages 73 to 76.)

LARGE quantities of telephone material are required by the Australian Postmaster-General's Department. Mechanical stokers are required by the Croydon Corporation. The Kendal Corporation are applying to the Local Government Board for a loan of £10,000 for the construction of a new generating station. The Woolwich Borough Council has applied to the London County Council for a loan of £2,610 for electrical extensions. The London County Council require six electrically-propelled stores transporter vehicles. The Finance Committee of the London County Council recommend a loan being granted to the Poplar Borough Council for £22,180, in connection with the electricity undertaking. It is announced that large contracts in connection with the Moscow tramways have been awarded to Messrs. Dick, Kerr & Co., and the British Insulated & Helsby Cables, Ltd. The Hampstead Borough Council has decided to fix a Berry series gear in all their sub-stations, the experiments which have been carried out in one of the sub-stations having proved successful. For the information of wiring contractors we give particulars of a large number of buildings about to be erected in London and the provinces. (Pages 76 to 78.)

THE Metropolitan District Railway Bill, which provides for the issue of £750,000 prior lien debenture stock, has been passed by a Committee of the House of Commons. Another Committee of the House of Commons has passed the South Wales Electrical Power Distribution Company's Bill, under which the company's power stations have been transferred either to individual companies or to the local authorities. (Page 79.)

A MEETING of the holders of Underground Electric Railways Company of London unpaid coupons for interest in the profit sharing secured notes of the power-house debenture and power-house second debentures, has approved arrangements between the company and the Westminster Bank, Ltd., under the financial scheme recently published. The British Aluminium Co. invite subscriptions for £700,000 5 per cent. redeemable mortgage debenture stock, and the Electric Taxicab Co. is offering 300,000 ordinary £1 shares for the purpose of placing electric cabs in the streets of London. (Page 80.)

COL. H. A. YORKE'S report on the fatal accident last February between Tividale and Oldbury on the system of the Birmingham & Midland Tramways Co., attributes the occurrence to the breakage of a wheel when passing through the points. (Page 71.)

Digitized by Google

A DESCRIPTION is given under "Electrochemistry and Electrometallurgy" of a large new tank house and copper furnaces, which the Karitan Copper Co. have recently added to their works. (Page 85.)

AMONG the Patent Specifications published by the Patent Office on Thursday last, is one by H. T. HARRISON and HUGO HIRST relating to slow burning electrodes for flame arc-lamps. The manufacture of tungsten filaments is the subject of a specification by the BRITISH THOMSON-HOUSTON CO., and the FELTEN & GUILLEAUME FAHMEYERWERKE AKT.-GES have one relating to variable speed single-phase commutator motors. A specification by J. T. IRWIN describes an oscillograph in which the movement of the mirror is controlled by the electrostatic attraction between metal diaphragms and fixed discs. A method of starting a mercury vapour lamp without tilting is described in a specification by P. H. THOMAS, and the SIEMENS-SCHUCKERT-WERKE have a patent referring to methods of starting and running three-phase motors off single-phase supply circuits. An application for amendment to a specification relating to telegraphic apparatus has been made by S. G. BROWN. (Page 86.)

THE technical discussions at the meeting of the Incorporated Municipal Electrical Association this year were, as usual, largely devoted to a comparison of opinions and experiences on points of detail which are all-important to the electrical engineer, and we have no doubt that our lengthy report of the Proceedings will, for this reason, be appreciated by all our readers, whether they be municipal electrical engineers or not. On matters of more general principle, the main subjects were the use of gas engines in electricity works and the application of accumulators for the purpose of taking the actual daily peak loads. On the gas engine question opinions are still divided; their champion, Mr. ANDREWS, has apparently made some converts so far as the gas engines themselves are concerned, but he was given a broad hint that he must turn his attention to the gas producer as well as to the engine itself. Mr. TAYLOR'S proposal to employ accumulators on a grandiose scale received little support, and we cannot but think that the battery makers themselves were rather shy of identifying themselves with his conclusions. It is fair to state, however, that subsequent conversation with their representatives after the meeting revealed the fact that they are quite prepared to give maintenance contracts on their usual terms for batteries which are to be discharged regularly at the one-hour rate, and that they would also guarantee good watt-hour efficiencies under these conditions. On the other hand, it must not be forgotten that even a momentary serious overload at the time of this maximum rate of discharge might go far to ruin the battery which is to be depended upon by Mr. Taylor to take the next day's peak load. It will require more than Mr. Taylor's painstaking deductions from diagrams and tables to convince the station engineer that his proposition is a sound one.

IN view of the large financial issues which have to be decided by Electricity Committees and their engineers, it is of interest that a question involving only the expenditure of a few pounds in each individual case should obtrude itself more or less prominently at every annual meeting of the Incorporated Municipal Electrical Association. We refer to the oft-repeated grievance that the delegates to the Convention sent by those Local Authorities whose accounts are subject to Local Government Board Audit, have to pay their own expenses. In the case of the Corporations which are happy in the possession of elective auditors, no question is asked apparently, and the expenses of the councillors and engineers who attend the Convention are paid out of the funds of the Department; but the Local Government Board is adamant. Although the expenses cannot be great in any case, it appears to be an absolute fact that the liability upon the individuals to pay them has actually acted as a serious deterrent to joining the Association. It was stated that some of the London Borough Councils had declined to join for this reason, and that some which had formerly belonged, had even withdrawn their membership on this account; no less than 64 municipal electricity committees are not represented on the Association, and it is suggested that in many cases this matter of expense is to be taken to explain their absence. So far as a means of remedying the evil is concerned, there appears no definite way out of the difficulty. If the annual subscription alone were the deterrent, the ingenious suggestion that there should be a subscription to the published "Proceedings," which should cover the subscription to the Association, could be adopted, but we presume that it is the actual travelling and out-of-pocket expenses of the delegates that are more thought of. An obvious remedy so far as the engineers are concerned, is to make it clear that they are expected to attend the meetings of the Association, and that their salary is computed on this basis, but this would be of little comfort to the unpaid councillor who desires to accompany the engineer. The same difficulty of expense is what stands in the way of the adoption of the proposal that there should be one or more assistant engineers' conventions during the year, and in this case the remedy we have just mentioned is quite applicable. The chief, who is as a rule responsible for fixing the salaries as well as choosing his assistants, should make it a condition that his assistants should join the Association, and that they should attend all its meetings, for which leave can be granted. The correspondents whose letters we publish this week are both Chief Assistants of electricity works of important towns, and their views should carry weight.

THE announcement is made in another column that a scheme is on foot for the placing on the London streets of a large number of electrically-driven "taxi-cabs." The past history of electric cabs in London has not been a bright one, and everybody will remember the dismal failure of an early attempt in this direction. Since then, however, there has been a good deal of experience with accumulator road traction. Its limitations, as well as its capabilities, are now well understood, and, we may say, by no one better than the company under whose technical management the vehicles are to be. The crux of the whole matter is, of course, the ability of the batteries to stand the heavy work demanded, without excessive cost of maintenance. The estimated expenses given in the prospectus of the new company that is being formed are based on systematic observations of work of a similar nature, and it is important to note that the vehicles will be under the charge of the same engineers. There is thus

Digitized by Google

nothing experimental on the technical side of the venture, and considering that the advantages of the electric cab in respect of silence, freedom from smell, steadiness, &c., are just of the kind which appeal to the public, we see no reason why excellent results in the matter of receipts should not be obtained. Its capabilities for speed may not equal those of the petrol vehicle, but this may be a blessing in disguise, as not presenting the same temptation to reckless driving which is but too often succumbed to by the newly-fledged driver of the petrol taxicab.

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, JULY 9TH.

Tramways and Light Railways Association.

11 a.m. First Day of Annual Congress. Meeting in the Congress Hall of the Franco-British Exhibition, when Sir Clifton Robinson (vice-president) will give a lecture on "The Tramways of the World," followed by a Paper on "Tramway Rail Joints," by Mr. A. H. Gibbings.

FRIDAY, JULY 10TH.

Tramways and Light Railways Association.

11 a.m. Second Day of Congress. Meeting in the Congress Hall of the Franco-British Exhibition, when Prof. C. A. Carus-Wilson will deliver a lecture on "Rail Corrugation."

7.30 p.m. Association Dinner at the Banqueting Hall of the Franco-British Exhibition.

SATURDAY, JULY 11TH.

Mining Exhibition.

Opening Ceremony at Olympia.

Accident at a Motor-car Works.—In the course of some experiments on electric accumulators, which are being carried out by Mr. A. P. Strohmenger, Analytical Chemist, at the premises of Messrs. Holmes & Co., Petrol and Electric Motor-car Builders, 37 and 38 Margaret Street, W., there was occasion to prepare a mixture of sulphuric and nitric acid. The fumes arising from the tank containing the mixture attracted the notice of a passer-by on Saturday last, and an alarm of fire was raised. The firemen, not knowing the nature of the contents of the tank, opened a tap and allowed the contents to flow out over the concrete floor towards a drain. This, of course, considerably increased the amount of fuming, and sixteen officers and men of the fire brigade staff were quite overcome. Eight members were seriously affected, and some had to be conveyed to hospitals.

Infringement of Electrical Patent.—On Tuesday, in the King's Bench Division of the High Court, Mr. Justice Channell had before him the case of Hills' Patents, Ltd., *v.* Dick, Kerr & Co., Ltd. The question had been raised as to whether or not Mr. H. F. Hills, one of the two plaintiffs in the action, should not be struck out, on the ground that the statement of claim which had been delivered disclosed no right of action by Mr. Hills. The defendants took out a summons to have Mr. Hills dismissed from the action. The summons came before Master Chitty, and he ordered that a question on a point of law be argued, and that order was confirmed by Mr. Justice Ridley. The action was brought to restrain the infringement of letters patent 28,932 of 1902, the patent being known as an improved safety apparatus for use in overhead electric tramways. Hills was the inventor of the patent, and had parted with his interest in it to a company, and the company had all the rights in respect to it. Hills assigned the patent to the company, and that assignment was subsequently registered. Although the assignment was not registered until after the date of infringement of the patent, it was submitted that Hills ought not to be a co-plaintiff. Mr. Justice Channell, in giving judgment, said that Mr. Hills ought either to be plaintiff alone, or joint plaintiff in respect to damages prior to the actual assignment. That being so, it was sufficient for disposing of the motion, which, he said, he must dismiss, the costs to be costs in the cause.

Wireless Apparatus on Channel Boats.—The Great Eastern Railway Co. have fitted the turbine steamer *Copenhagen* and the twin-screw steamer *Dresden*, with wireless telegraphy apparatus, enabling the public to send telegrams from on board these vessels. The other steamers on the Hook of Holland service are also being fitted with wireless apparatus.

CORRESPONDENCE

ASSISTANT ENGINEERS AND THE I.M.E.A.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—Your suggestions for rendering this Association more useful to the assistants in municipal electricity works are of great interest.

The deputy engineers form a numerous body, and there is a growing tendency amongst committees to select managers from their ranks, which testifies to their ability and to the confidence reposed in them by their chiefs. The days of frequent change and rapid advancement have apparently passed, and the younger members of the profession can no longer rely upon confidence and close attention to advertisement columns to secure them rapid increases in salary and responsibility. Great widening of the business of electricity supply and close specialisation by designers and makers of electrical plant render it more and more necessary that the man who aspires to a general manager's position should supplement his theoretical knowledge and training in the works by wide experience of modern practice in building up and administering electric supply systems, and by continuous study of modern thought and methods in connection with the larger problems of municipal finance, cultivation of the demand for public supply, and the influence of purely commercial considerations upon engineering ideals.

It is obvious, therefore, that the Association could be of the greatest value to officials whose attention is practically confined to routine duties and the work of the purely technical societies. That it is undesirable for an assistant to be away from his works for any length of time in the absence of his chief is too obvious to need discussion or to constitute a grievance in the mind of any man who appreciates the importance of his position. But it should not be too difficult to arrange for a distinct convention or series of meetings at some time of the year other than the height of the business or holiday season. If such meetings were held in a large industrial district, more or less central geographically, it should be possible to secure a good attendance of assistants with a minimum of inconvenience to engineers and expense to those attending. The latter question must not be neglected, as the salaries paid are not always princely, and there would possibly be some difficulty in persuading an electric light committee to grant the necessary funds, unless some conspicuously ingenious member could make out a case for charging them to capital, "Staff betterment A/c" perhaps. A convention of several days' duration might have advantages over a number of separate meetings, inasmuch as travelling expenses would be reduced, local works and stations could be visited, and a certain amount of recreation, which could be worked in without detracting from the utility of the meetings, would help to act as an incentive to the more distant members. In short, the methods adopted with such success by the presidents and organisers of the regular annual conventions might be followed on a more or less modest scale according to the support received.

Some expression of opinion on the part of the Council concerning this subject would, in the writer's opinion, be of great interest, and possibly lead to further suggestions being made.

I am, Sir,

Yours faithfully,

July 7th, 1908. J. W. B.

[Another letter on this subject will be found on p. 70; the matter is also commented upon in our Editorial Notes.]

ELECTRIC TAXIMETER CABS FOR LONDON

A COMPANY has been formed under the name of the Electric Taxicab Co., Ltd., to provide London with a service of four-seated electric taximeter-cabs, which, to use the words of the prospectus published on another page, will be particularly suitable for the conveyance of passengers with luggage to and from the London railway stations, as they will be provided with a luggage roof capable of carrying as much luggage as the ordinary four-wheeled cab. The cleanliness, silent running, and absence of smell and smoke render the electric cab "eminently desirable." The company has entered into a contract with the Electromobile Co. by which the latter company agrees to do the following: (1) To supply 100 electric cabs complete, except for batteries, tyres, and taximeters, at the price of £360 per cab, with the option to the company to require them to supply a further 400 cabs on the same terms; (2) to garage at their Mayfair garage the first 100 electric cabs owned by the company for a fixed term of three years for a sum at the rate of £60 per cab per annum; (3) to supply 150 suitable batteries for the running of these cabs at the price of £60 per battery; (4) to charge with electricity, and to renew and maintain all such batteries for a sum equal to threepence per mile run; and (5) to maintain the chassis and bodies of these cabs in a proper and serviceable state of repair for a sum at the rate of £45 per cab per annum.

The chassis of the car, which is illustrated below, will be substantially of the same type as those used by the Electromobile Co. for their private carriages, but will be especially

ELECTRIC TAXIMETER CAB.

built for the new company in accordance with the requirements of Scotland Yard. The motor is rated at 8 B.H.P. at 1,500 r.p.m. for continuous load, but can exert more than 100 per cent. overload for short periods. It is of the iron-clad type, bi-polar, and series-wound, having two separate commutators connected to separate armature windings. The motor drives through a double train of double helical gearing to the differential, and thence to the hubs of the rear wheels, by live shafts, which revolve in an external tubular axle. This axle is stationary except for the slight radial movement permitted by the suspension springs carrying the motor.

Further particulars of the motor, accumulators, and method of control employed by the Electromobile Co. were given in a description of an electric ambulance supplied by that company to the City Police, which appeared in ELECTRICAL ENGINEERING, Vol. I., p. 653; the equipment is practically the same.

The Electromobile Co. have at present over 200 cars in their garage at Hertford Street, Mayfair. During the next few months the larger number of the privately owned cars kept in the garage will not be required by their owners, and there will be ample space and facilities for dealing with the first hundred taximeter-cabs as arranged in the contract. Ten of the taximeter-cabs will be running almost immediately, and in the course of two or three months the cabs will be delivered at the rate of six per week until the first 100 are running. The Electromobile Co. have already purchased a large block of buildings adjacent to their garage, and building will shortly be commenced on this site. As soon as the accommodation is again insufficient, the taximeter-cab company will build a garage of their own. The garage in Hertford Street, which was described and illustrated in ELECTRICAL ENGINEERING, Vol. II., p. 793, covers over half an acre, and is built in three stories, of which the basement forms the motor-generator room, charging and battery rooms, and also the repairs department. The ground floor, at the entrance of which are the accumulator lifts and pits, is adapted for storage purposes, and the next floor will accommodate some 150 cars. Current for charging is taken at a particularly low rate from the Westminster Electric Supply Co. at 400 volts, and converted to 110 volts by the motor-generators. At least three different makes of accumulators are in use in the Electromobile Co.'s cars, and after the contract number of 150 batteries has been supplied to the new company, the latter is free to use any other make which may be more suitable.

The Electromobile Co. has had some five years' experience in the running and management of electric cars, and the total mileage of the cars owned by the company amounts to over 2,000,000. On the basis of this experience, the Managing Director of the Company, Mr. J. G. Chambers, has estimated the following probable earnings and expenses:—

The authorised tariff for a motor-cab, fitted with a taximeter, and licensed to carry four persons, is eightpence for the first mile, or for the first period of time not exceeding ten minutes. For each succeeding quarter of a mile or period of time not exceeding two and a half minutes, twopence.

Working upon this tariff the average gross earnings should not be less than two pounds per cab per day. Deducting seven shillings a day for the driver, there will remain an average gross profit per cab per day of £1 13s.

Expenses.

	Per day per cab. s. d.
1. Garage accommodation and operating costs	2 8
2. Maintenance and upkeep of the chassis and bodies, including lubricating oils and stores	2 8
3. Electricity and maintenance and replacement of the batteries	9 2
4. Tyres (supply and maintenance) ...	5 0
	19 6

These expenses are calculated on the basis of a cab-mileage estimated to be sufficient to earn the above sum of £2 a day. Thus:—

	£ s. d.
Gross profit per cab per day	1 13 0
Less expenses	0 19 6
Balance of profit per cab per day ...	£0 13 6

Considering now the total number of cabs running, we have the following:—

500 cabs at 13s. 6d. profit per cab per day (reckoning six days a week) = say ...		£105,630
Less annual charges:—		
Taximeters to be rented at £7 per annum per cab ...	£3,500	
Licenses: £2 15s. per annum per cab	1,375	
Insurance against fire, accidents, and third-party risks per annum	12,500	
Provision as reserve to replace the whole cost of the chassis and bodies in seven years (the batteries and tyres being maintained out of revenue) on the basis of the sum which would be required if invested at 3 per cent. per annum compound interest	23,490	
		40,865
Profit balance ...		£64,765

This balance of £64,765 will—after providing for administration expenses, directors' remuneration, and, if thought desirable, further reserves—be available for dividends on

Digitized by Google

£300,000 share capital. The above figures are based upon a complete scheme of 500 cabs garaged and run by the company in and from its own garage, and the profits shown should be earned when all the cabs are so garaged and running. The delivery of 500 cabs, and the acquisition of a garage sufficient to accommodate so large a number, must of necessity take time, but the directors anticipate that the whole of the cabs ordered can be running on the streets within two years. The first 100 cabs should be running on the streets within eight months. As above stated, these first 100 cabs will, according to the contract entered upon with the Electromobile Co., be housed and maintained in working condition by that company. The payments provided by such contract, reduced to a basis of a daily charge per cab, will, in respect of each cab so garaged, increase the before-mentioned figure of daily cost per cab of 19s. 6d. to 22s. 0d. per day, and consequently reduce the before-mentioned figure of profit per cab per day from 13s. 6d. to 11s. 0d. This reduction in the profits in respect of the first 100 cabs will be more than compensated for by the avoidance of having to work in the early days of the company on the unremunerative lines of a large garage only partially filled, whilst the company will also be able, during this initial period, to obtain the fullest benefit of the technical experience of the Electromobile Co.'s staff in connection with the working of electric carriages. Although provision is made in the above estimate for the replacement of the whole of the cost of the chassis and bodies at the end of seven years, this must not be taken to indicate that the cabs will be worn out at the end of that term. Many of the private carriages of the Electromobile Co. have been in constant service for over five years, and it is stated that they show now scarcely any sign of depreciation, whilst the freedom from breakdown is almost complete.

In conclusion, we wish to express our thanks to the Electromobile Co. for much information with respect to the arrangements which have been made for the housing and upkeep of the new company's cabs.

THE THIRTEENTH CONVENTION OF THE INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION

ON the Incorporated Municipal Electrical Association resuming its proceedings at Nottingham on Thursday, after a day's relaxation in Dovedale during exceptionally fine weather, the first business was the holding of the Annual General Meeting for the election of the new President and Council, the choice of a place of meeting for next year, and the reception of the Council's Report. The remainder of the Convention was devoted to the discussion of technical Papers.

Thursday, July 2nd.

The Annual General Meeting was held in the morning at University College. The first business on the agenda was the election of officers and Council for 1908-9.

The ballot for the new Council resulted as follows:—

PRESIDENT:

*S. L. Pearce (Manchester).

VICE-PRESIDENTS:

W. W. Lackie (Glasgow), (*Senior*),
*J. Christie (Brighton), (*Junior*).

PAST PRESIDENTS:

J. E. Edgcome (Kingston-on-Thames), S. E. Fedden (Sheffield), H. Talbot (Nottingham).

HON. SOLICITOR:

Alderman G. Pearson (Bristol).

HON. TREASURER:

J. E. Edgcome (Kingston-on-Thames).

HON. SECRETARY:

H. Faraday Proctor (Bristol).

COUNCIL:

Alderman Bruce (Sunderland).
C. E. C. Shawfield (Wolverhampton).
Alderman J. P. Smith (Barrow-in-Furness).
G. Wilkinson (Harrogate).
T. P. Wilmshurst (Derby).
*Councillor Howarth (Manchester).
*Alderman West (Coventry).
*Alderman Wilkinson (Luton).
*Councillor Sinclair (Swansea).
*A. C. Cramb (Croydon).
*A. A. Day (Bolton).
*V. A. H. McCowen (Salford).
*H. Richardson (Dundee).
*F. M. Long (Norwich).

New members of Council and members filling a new office are denoted by an asterisk. Mr. J. K. Brydges (Eastbourne), Mr. A. A. Day (Bolton), Alderman Dowson (Doncaster), Mr. V. A. H. McCowen (Salford), Mr. H. Richardson (Dundee), Councillor Sinclair (Swansea), and Alderman Wilkinson (Luton) retired from the Council in the ordinary course, and additional members had to be elected in the place of Sir John Turney (Nottingham), who retired owing to pressure of other business, with one year still to serve, and Mr. J. Christie (Brighton), who was elected Junior Vice-President. It will be seen that Mr. Day, Mr. McCowen, Mr. Richardson, Councillor Sinclair, and Alderman Wilkinson were re-elected.

The place of meeting for the 1909 Convention was unanimously decided to be Manchester, and Councillor Howarth, Chairman of the Manchester Electricity Committee, said he had been authorised to give the Association an invitation to go there, and to promise them a hearty welcome.

Mr. Standen Leonard Pearce is the son of the late Rev. Standen Pearce, of Crewkerne, Somerset. He was born in 1872 and educated at Bishop's Stortford College and Finsbury Technical College. In 1888 he was apprenticed to Messrs. J. G. Statter & Co. and after two years with them, completed his time with Messrs. Thos. Richardson & Sons, of Hartlepool. After over four years with this firm, the latter part of which he spent in the drawing-office, Mr. Pearce entered the service of the

S. L. PEARCE, THE NEW PRESIDENT OF THE INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION.

Digitized by Google

British India Steam Navigation Co., of London, and was for two years with them in charge of a "watch" on different vessels. From 1896 to 1899 Mr. Pearce was with the Metropolitan Electric Supply Co., and then joined the British Thomson-Houston Co. during the construction of the Central London Railway, afterwards acting for a short time as Superintendent Engineer at the Railway Co.'s power-house. In 1901 he was appointed Deputy Engineer to the Manchester Corporation Electricity Department, and in 1904, on the resignation of Mr. Metzger, he received the appointment of Engineer-in-Chief.

Mr. Pearce was Chairman of the Manchester Local Section of the Institution of Electrical Engineers in 1905-6, during which year he acted as Chairman of the Local Reception Committee in connection with the visit of the foreign kindred institutions. He was also a Member of Council of the Institution of Electrical Engineers in 1907-8. He has read the following Papers: "Polyphase Sub-Station Equipment and Working" (I.M.E.A., 1904), "Manchester Tramways Power Supply" (Inst. Electr. Engrs., 1905), "Steam Turbines" (Manchester Section Inst. Civil Engrs., 1907), and "Steam Turbine Engineering" (Manchester Association of Engineers, 1908).

Mr. Pearce, in addition to being the City Electrical Engineer at Manchester, is also responsible for carrying out the extensions there. A 6,000-kw. turbo-alternator put down to his specification and under his supervision was recently started, and another of similar size is in hand, in addition to extensions of the boiler plant, and new arrangements for the water supply. Mr. Pearce has identified himself with the work of promoting and organising the electrical exhibition to be held in Manchester in October, and is taking an active part in the preparations.

ANNUAL REPORT.

The annual report of the Council for the year ended June 30th, 1908, which is abstracted below, was taken as read:

The membership of the Association now stands at 385, made up as follows:

Committees (Members)	... 165
Chief Electrical Engineers (Members)	... 168
Honorary Members	... 2
Chief Assistants (Associate Members)	... 10
Assistants (Associates)	... 40
	385

After allowing for resignations, removals, and lapses due to members leaving municipal employ, there is a decrease of seven on last year's total, principally in the class of Associates. During the last two months 13 municipalities and 11 engineers have joined the Association.

Council meetings have been held in London, Nottingham, and Wolverhampton. There have also been a number of meetings of Standing and Special Committees and Sub-Committees.

ACCOUNTS OF LOCAL AUTHORITIES.

A Sub-Committee of your Council is co-operating with the Municipal Tramways Associations in considering the report of the Departmental Committee appointed to inquire into the accounts of local authorities.

LOCAL AUTHORITIES LIABILITY UNDER THE EMPLOYERS' LIABILITY ACT, &C.

The attention of your Council has been drawn to the liability of a local authority in connection with damages to persons or property occurring in connection with works carried out for the local authority by contractors. This liability divides this up into two sections—first, the liability caused by an accident to the contractor's workmen under the Employers' Liability Act, and secondly, the third-party risks, *i.e.*, accidents or damages caused to persons or property not under the control of the contractor. Several Corporations have been communicated with to ascertain the clauses in use in contracts for safeguarding the Corporations in question against such liability. Whilst it appears to be the invariable practice to insert a clause in contracts making the contractor responsible for all accidents and damages, it appears to be almost exceptional that the precaution is taken of requiring the contractor to take out an insurance policy under the Workmen's Compensation Act, in the name of the Corporation, or, in the event of such already existing, of adding an endorsement to such policy showing that the insurance company relieves the Corporation from all liability in connection with the works. This appears to be necessary owing to the fact that a person sustaining an injury will often prefer taking action against a Corporation rather than against his employer, very probably on account of the general impression that it is more easy to get judgment against a Corporation than any other body or person, in the case of accidents or damages. Such a course seems to protect a Corporation as far as is possible, regarding the first-named difficulty, but it is understood that insurance companies generally will not accept third-party risks, enabling Corporations to be insured against liability for accidents to third parties, and this matter has yet to be looked into more fully. Your Council will welcome any suggestions with a view to overcoming this difficulty.

SUPPLY OF ELECTRICITY BILL.

Early in the session your Council circularised the members asking them to use their utmost endeavours to get the Bill passed into law, and in February last the matter was discussed at a special general meeting of the Association held in London. A full report of this meeting was afterwards circulated to the members, and will be embodied in the proceedings. The Board of Trade have been approached again, relative to this matter, and whilst they regret that they consider the present time to be unsuitable for making an effort to get the Bill passed, they state that they will put it forward at the first opportune moment. The Board of Trade have been asked, and have promised to consider the introduction of clauses, to enable Corporations to supply fittings, &c., on hire.

TRAVELLING STUDENTSHIP.

Mr. R. McCourt (Associate), Mains Superintendent, Harrogate, has submitted his report of his tour of inspection of various electricity works in London and the provinces, and the same has been approved by your Council, and will be published in the proceedings. It is hoped that it may be the means of stimulating others to compete, as the result has shown that the scheme is of the greatest practical benefit to the holder of the scholarship. Your Council regret to report that there have been no entries for the scholarship this year.

INCOME-TAX AND DEPRECIATION.

Representatives of your Association have met the Sub-Committee of the Institute of Municipal Treasurers and Accountants, relative to the absence of uniformity of treatment accorded to Corporations as regards depreciation of assets for income-tax purposes, and the desirability of obviating the necessity for appeals, by the introduction of more systematic treatment of depreciation of assets of local authorities charged to capital account. The matter is still under consideration, and negotiations are proceeding with the Board of Inland Revenue.

HOME OFFICE REGULATIONS.

Your Council have to record that they gave very careful attention to the draft regulations issued regarding the generation, distribution, and use of electrical energy under the Factory and Workshop Act, 1901. Combined action was taken with the Association of Municipal Corporations, and most valuable amendments were secured.

FRANCO-BRITISH AND MANCHESTER EXHIBITIONS.

Your Association is represented in the Electrical Engineering Section of the Franco-British Exhibition, and also on the Executive Committee of the Manchester Exhibition to be held in October next, by the President, Mr. H. Talbot.

GREAT EASTERN RAILWAY GENERAL POWERS BILL.

The attention of your Council was called to Clause 19 of this Bill, which, it was felt, might seriously endanger the interest of municipal electrical undertakings if it passed into law. The original clause gave the company power to supply from their works at Parkeston or elsewhere, either in bulk or otherwise, electrical energy not required for their own purposes to any tenants of the company or occupiers of premises connected by siding with any railways of, or leased to, or worked by, the company, and to any local or sanitary authority, or to any company authorised to supply electrical energy. Your Council decided to take steps to oppose the Bill, and the clause was subsequently modified, so as to permit such power supply only to the company's lessees and tenants or occupiers. Your Council was preparing to proceed in the matter when intimation was received that the clause had been withdrawn.

ALLOCATION OF WAGES OF WORKMEN ON PERMANENT STAFF.

This matter has not been pushed so vigorously as last year, owing partly to the general political unrest throughout the country, and partly to time having been taken up so fully in connection with the Home Office regulations. It is, however, being kept well in view, and further steps will be taken to obtain an equitable ruling as to the allocation of all wages incurred in connection with capital works.

QUALIFICATION FOR MEMBERSHIP.

It should not be forgotten that heads of electrical departments are now, under certain conditions, eligible for full membership, and chief engineers can do much to extend the scope of the Association by enrolling eligible members of their staff. Associates have not the advantages which would accrue to them were they eligible for full membership, but, on the other hand, their subscription is a nominal one, and it is obviously to their advantage in many ways to be affiliated with a representative Association.

Digitized by Google

DISCUSSION.

Discussion took place upon various matters touched upon in the report.

Allocation of Wages of Permanent Workmen.

Mr. H. Collings Bishop (Chief Electrical Engineer, Newport) asked if the Council had been able to do anything further in this matter. At Newport there had been an instance where the officers of the Local Government Board had charged to revenue a fairly large sum, which the undertaking had previously put to capital for wages in past times, and it might help other authorities to know that they had got several members of Parliament to move in the matter in the House of Commons, and ask a question. The point was referred to Mr. Burns directly, and within two days the whole amount was remitted.

Associate Members and Associates.

In declaring the annual report open for discussion, the President referred to this matter. He said it was very difficult to get Associates to join or to read Papers.

Although the Studentship was started two years ago, only one member had given a Paper, and a very good Paper it was. Although they had since tried all possible means of inducing associates to join, they had not been successful. The subscription had been reduced by some 50 per cent. in order to try and make things easier for them, and still they would not join. He thought it would be a very good thing on the part of engineers and chairmen of committees if they could see their way to do something to get these people to join as associates. They had sent 700 or 800 circulars around, but had only received about 60 replies. This showed what little interest was taken.

Mr. A. T. Yates (Swinton and Pendlebury) thought engineers could do a great deal by bringing the matter before their assistants. He would also like to throw out a hint to the Council. Another association to which his Corporation belonged offered prizes for Papers read by associates, and it generally followed that associates reading the Papers joined the Association afterwards.

The President said that the Association had already practically done this in offering a £10 prize for the best associates' Paper.

Local Authorities' Liability under the Employers' Liability Act.

Mr. A. C. Cramb (Croydon) wished to know whether the Council had any actual cases with which there had been trouble up to date. He understood that the average contractor covered the Corporation as to any liability of this sort.

Mr. S. L. Pearce (Manchester) said this matter came under the consideration of the Council owing to an accident which occurred in Manchester to a contractor's man working in a Corporation sub-station. The workman did not bring an action against his own employer, but against the Corporation, and he succeeded in getting very substantial damages. Seeing that it was possible for this to happen elsewhere, he brought the matter before the notice of the Council, for after consulting the Manchester Corporation legal department they were advised that in a case of that sort it was almost impossible to draft any clause that would meet the exigencies of the particular circumstances. When a case of this sort came before a jury, the verdict was almost sure to be against the Corporation. Mr. Faraday Proctor, the honorary secretary, had written around for copies of clauses in the various forms of contract prepared by various town clerks, and these were still under the consideration of the Council, but up to the present he did not think the Council had decided upon any clause which would fully meet every condition that might arise.

Mr. C. Turnbull (Tynemouth) asked if the Corporation had recovered from the contractor.

Mr. Pearce said no. In reply to further questions, he added that in this particular case it was proved to the satisfaction of the Court that there had been contributory negligence on the part of the Corporation.

Alderman Pearson (Honorary Solicitor) confirmed the facts stated by Mr. Pearce with regard to the action of the Council in the matter of preparing a standard clause. They had in Bristol a clause which was as good as any he had yet seen, but copies of others had still to come in, and they hoped to be able to propose something which would suit all conditions. He thought Mr. Pearce's remarks about contributory negligence rather explained the result of the action in that instance; at the same time it was a very serious thing that when such an action came before a jury, with an injured workman on the one side and a Corporation on the other, there was not much doubt as to which way the verdict would go, if there was the slightest justification for it. Therefore they should all be careful to see they had in their contracts an indemnity clause with regard to third party risks and with respect to risks such as these. In the course of the next few months he hoped the Council would have such a clause, which they would be justified in offering for adoption by the general body of municipalities.

Mr. C. C. Aichison (Rochdale) said he supposed the Manchester Corporation were insured, as most corporations were, under the Workmen's Compensation Act, and that therefore the risk would be taken up by the insurance company. The contractor would naturally be insured himself, and if the Corporation made sure that he was, then the liability would be very largely covered, and it would lie between the two insurance companies to settle the matter.

Mr. Pearce said at Manchester they generally suggested that the contractor should pay the premium in the name of the Corporation, so that they had a direct claim on the insurance company themselves.

Supply of Electricity Bill.

Mr. A. C. Cramb (Croydon) said he would have been glad if the Council had been able to report something more than they had been able to in this matter. They went on year by year, and still no progress was made towards securing the passing of this necessary Bill.

The President said it was the fault of Parliament, and not of the Association.

Mr. Cramb said that did not help matters forward at all. Many municipalities had the powers which would be granted under the Supply of Electricity Bill, and he thought it was time all municipalities had them without having to go to Parliament specially. For instance, any authority inside the county of London could wire houses, hire out fittings and motors, &c., and yet, half a mile over the border, the municipalities could not.

Alderman Pearson said that it was now two years since he had formed one of a deputation which waited upon Sir Hudson Kearley, who professed the most profound desire to get the thing through, if he could get a short time to take it up, but they might take it that they would see nothing of the Bill this session. The Supply of Electricity Bill was certainly one of the most important Bills dealing with the electrical industry of the country that had been before Parliament in his time, and it did seem a monstrous thing that when there was absolute unanimity of all persons in the industry that these powers were necessary and ought to be given, Parliament could not find time to put a small Bill like this through; it was absolutely unopposed, so far as he knew, by any municipality in the country.

The Proposed Home Office Regulations.

Mr. E. B. Vignoles (Grimsby) asked how many Corporations contributed towards the opposition of the Association at the Home Office inquiry into the proposed regulations concerning the electrical industry.

Alderman Pearson said that about 150 contributed, some contributing an absolute part and others limiting the amount they paid. The total cost, as far as the municipalities were concerned, was about £650. The total cost of the inquiry he should be very sorry to estimate.

Membership: L.G.B. and Delegates' Expenses.

Mr. A. C. Cramb (Croydon) said that if the Council could bring pressure to bear upon the Local Government Board to allow the expenses of delegates to the annual conventions, there would be a perceptible increase in the membership.

Alderman Pearson said this question had been before the Council for a considerable time, and they had endeavoured to get an interview with Mr. John Burns upon the subject, but although they had obtained the unanimous support of at least forty members of Parliament, Mr. Burns had decided that he would not hear what they had to say. He was bound to say he did not think there was the slightest chance of moving the Local Government Board in the matter, and inducing them to allow the expenses of delegates attending their conventions wherever the boroughs were subject to Government audit. Members of Boards of Guardians got all their expenses paid, but it was improper for a member of a town council. The London boroughs, who were under Government audit, had, in consequence, in some instances, declined to join, and in others they had been obliged to withdraw from the association.

Mr. A. G. Cooper (Colne) pointed out that Urban District Councils were also subject to Government audit, and thus came under the ban of the Local Government Board in this matter.

Mr. C. C. Atchison (Rochdale) asked if it was all due to the Local Government Board, for he noticed that there were 64 corporations not represented on the Association.

Mr. C. McArthur Butler, the secretary, said that all committees and engineers who were likely members, were circularised two or three times a year.

Mr. Atchison suggested that, in order to bring before the notice of some of the Councils who were not members the advantages of being members, they should invite a few of those in the immediate neighbourhood of the town in which the convention was being held as guests at each convention.

Mr. C. Furness (Blackpool) disagreed with this for the reason that it would discourage membership.

Bailie Murray (Edinburgh) said the attitude of the Local Government Board in the matter of expenses seemed strange to those in Scotland, because they had no difficulty there. The sooner Scotland annexed England, therefore, so far as this was concerned, the better.

Some other speakers took part in the discussion on this matter,

Digitized by Google

one suggesting that the amount of the engineer's salary for the year should be increased by the amount of his expenses. Another gentleman urged that a subscription to the proceedings should cover the subscription to the Association. Curiously enough, the Local Government Board sanctioned subscriptions to proceedings, and the difficulty could be got over in this way.

The PRESIDENT then moved the adoption of the report, which was seconded by Alderman J. P. Smith, of Barrow, and carried unanimously.

Mr. J. E. EDGCOME (Honorary Treasurer) then presented the annual balance sheet. There was very little discussion upon it, and it was carried unanimously.

POWER SUPPLY BY NON-STATUTORY POWER COMPANIES.

Bailie MURRAY (Edinburgh), in connection with the reference in the annual report as to the Great Eastern Railway (General Powers) Bill, raised the question of whether a railway company was entitled to grant wayleaves to a private company without Parliamentary powers to lay cables along the railway lines for the purpose of supplying electric power in competition with local authorities through whose areas the railway ran. This was threatened in Scotland, and at a convention of Scotch burghs the other day he had been instructed to see that the point was raised at this convention.

Mr. H. RICHARDSON (Dundee) said this matter was being viewed very seriously in Scotland, the fear being that a bogus company would be created with the sole object of being purchased, although they might never have a reasonable prospect of making a profit. They did not fear real and genuine competition under Parliamentary powers.

Alderman PEARSON said it was quite within railway companies rights to grant wayleaves of the kind referred to. He quite agreed with the remarks of Mr. Richardson as to the buying out of companies, as Bristol had suffered in this respect in regard to the docks. If the Scotch burghs were a little more persistent and brought this matter, not only before this Association, but also secured the support of the Association of Municipal Corporations and their own Municipal Association, he thought it might be possible by such combined action to bring pressure to bear on Parliament in order to protect the interests of municipalities owning electrical undertakings.

Bailie WIGHTMAN (Govan) asked what was the good of the Scotch Corporations belonging to the Association if they were not to receive assistance of this kind.

Several other members discussed the question of the possible effect of the action of railway companies in granting wayleaves to non-statutory power companies, and opinions seemed to be divided as to the seriousness of the question. Eventually Bailie Murray, of Edinburgh, moved the following resolution, which was seconded and carried with one dissentient:—"That it be remitted to the Council to consider the question of the proposed supply and sale of electricity by private companies by means of wayleaves obtained from railway and canal companies, to draw the attention of municipalities to the proposal, and the dangers of same, with power to consult and co-operate with the Convention of Burghs in Scotland, and the similar Association in England if so desired."

A vote of thanks was unanimously accorded to the retiring President, Mr. H. Talbot, on the motion of Mr. G. Wilkinson. In thanking the meeting for the vote of thanks, the President asked for Papers or suggestions for Papers for the next convention. Papers would be preferred from engineers of small stations, and from chairmen of committees.

Votes of thanks to the honorary officials closed the meeting.

On Thursday afternoon, two Papers were dealt with, both dealing with the construction, design, and working of electricity stations:

SOME CONSIDERATIONS ON THE DESIGN OF A GENERATING STATION.

BY H. RICHARDSON.

(*Chief Electrical Engineer, Dundee.*)

Foundations.—In most large towns near rivers or estuaries, the railways run very near the water, therefore sites near the water possess a double advantage. Unfortunately, when such land is to be had at a reasonable price, it is usually found to be filled-in or made-up land, reclaimed within a comparatively recent period. Therefore, viewed from a foundation standpoint, it is always very bad, unreliable, and, in many cases, contains the potentialities of chemical actions which will cause the authorities grave distress ere long with regard to all pipes, cables, &c., which have been laid in the ground, if they are not specially and expensively protected. The problem of securing foundations giving a maximum of stability with a minimum of cost is, however, an interesting point in connection with such sites, and much could be said thereon. The cheapest system is the construction of a large floating or raft foundation, the main object of which is to distribute the concentrated weights of the plant and buildings over such an area that the resulting intensity of pressure is less than the safe bearing capacity of the ground. The commonest method was to use a plain concrete raft of considerable thickness, but there are very few cases where this has not developed cracks, and unequal settlement of superstructures has occurred. Many such rafts have been reinforced with old tramway rails, but with little improvement.

We now come to piling foundations, and as wood piles particularly in such grounds as the above are liable to rapid deterioration, the tendency in view of the experience obtained latterly is to make use of reinforced concrete in the construction of piles. If carefully and properly executed, no better foundations can be made, taking into consideration maximum stability with minimum weight and cost. In very bad made-up ground containing much silt, with distances of 25 to 35 ft. to rock, a safe load of 60 tons may be allowed on any well-constructed pile. In connection with the driving of these piles, it is often specified that a weight equal to 2 tons, falling 3 feet, is to be used, giving a specified maximum amount of set such as ¼ inch for 10 blows, before driving is stopped. The author is of opinion that this results in a needlessly severe blow in ordinary practice, the change of velocity on impact being too great, resulting in damage to the heads of the piles, and causing much extra work and inconvenience. Piles should not be driven until from 50 to 60 days old at least. Even longer than this should be allowed for the concrete to set if possible. The cost of the foundation, including the raft, the piles, and reinforced foundation for the pipe track and reinforced pump chamber in the generating station at present being constructed by the author, was £5,800. The depth from ground level to rock was 30 ft.

Buildings.—The advantages of reinforced concrete construction may be carried beyond the actual piling, as it can be used to make a strong and light raft or floor over the heads of the piles and monolithic with them, forming a very complete and stable foundation for the superstructure. As regards superstructures, buildings made of brick or stone entirely are unnecessarily heavy and expensive, although this is the form generally adopted when an architect is allowed *carte blanche*. The heavy burden of capital expenditure unnecessarily carried by many stations has undoubtedly been largely contributed to by such useless extravagance further aggravated in many cases by equally useless and more sinful ornamentation. Reinforced concrete superstructures are not cheaper, the stability is in no way superior, and while certainly lighter, considerable inconvenience is met with in the fact that, once up, the design cannot be interfered with in the way of alterations without prohibitive cost. Also, so much depends, apart from the value of the system itself, on highly skilled and expensive supervision, and one weak part involves heavy consequential damage. The composite, building consisting of a steel skeleton filled in with light brick work, appears at the present time to be the most perfect system of building, giving, as it does, a minimum of cost and weight when considered in connection with its probable life, reliability, strength, adaptability, neatness, and appearance. If the insides of the buildings are to be lined for the sake of cleanliness, the author is of opinion that opalite or crystopal tiles are very much superior in appearance, cleanliness, and expense, to the ordinary glazed brick. In many stations having splendid engine-rooms, the boiler-houses are unnecessarily dirty, gloomy, and apparently neglected, for some unknown reason. The author does not admit that, under modern conditions, there is the slightest excuse for the boiler-house to be any dirtier than the engine-room. It is by far the most important part of a generating station, and should be treated as such, both in design and management. A very great deal can be said in support of corrugated iron buildings throughout. Their life, though short, is possibly amply long enough, and in any case it is merely a question of putting the shorter life and more expensive upkeep against the considerable difference in price. In most cases the steel skeleton building with corrugated iron walls is the right form to use if the locality of the generating station does not require æsthetic consideration.

Chimneys.—All the peculiarities of brick chimneys are well enough known, and, providing that great care is taken to spend some weeks after the work is finished in gradually heating up the chimney, there is, perhaps, nothing to beat it. The unsightly and apparently dangerous cracks are more often due to bad treatment than to faulty design or settlement.

An interesting modern development is the reinforced concrete chimney. The author had occasion to go very carefully into the merits of this form of construction, and came to the conclusion that there is a good deal to be said for it, because, owing to the simplicity of form, the before-mentioned disad-

Digitized by Google

vantages of reinforced concrete should not have an opportunity of attaining importance. Two of the firms which have built most of the reinforced concrete chimneys in existence were of opinion that such chimneys would stand a temperature at the base of 1,500 degrees F., without harm or deterioration, and claim that the usual fire brick lining is unnecessary, as they are mostly built with a separate internal concrete shell extending part of the way up.

The author was surprised to find that in comparing steel chimneys with brickwork the result is so very doubtfully in favour of the steel chimney. Dealing with chimneys from 120 to 200 ft. high, the steel chimney equals, and in some cases exceeds, the cost of the brick one, if the foundations are excluded, but as so many modern generating stations are built on very bad ground, the foundations have to be particularly good in both cases, so that the lower cost of foundations for the steel chimney is not in any proportion to its comparative lightness. On inquiry from several users of steel chimneys, it was found that their cost of upkeep is quite a considerable item, if they are maintained in a reliable condition.

The following are examples of comparative costs :—

Height and diameter	220 ft. by 11 ft.	80 ft. by 9 ft.
Brick chimney	£1,550	£400
Concrete chimney	1,300	470
Steel chimney	1,460	450

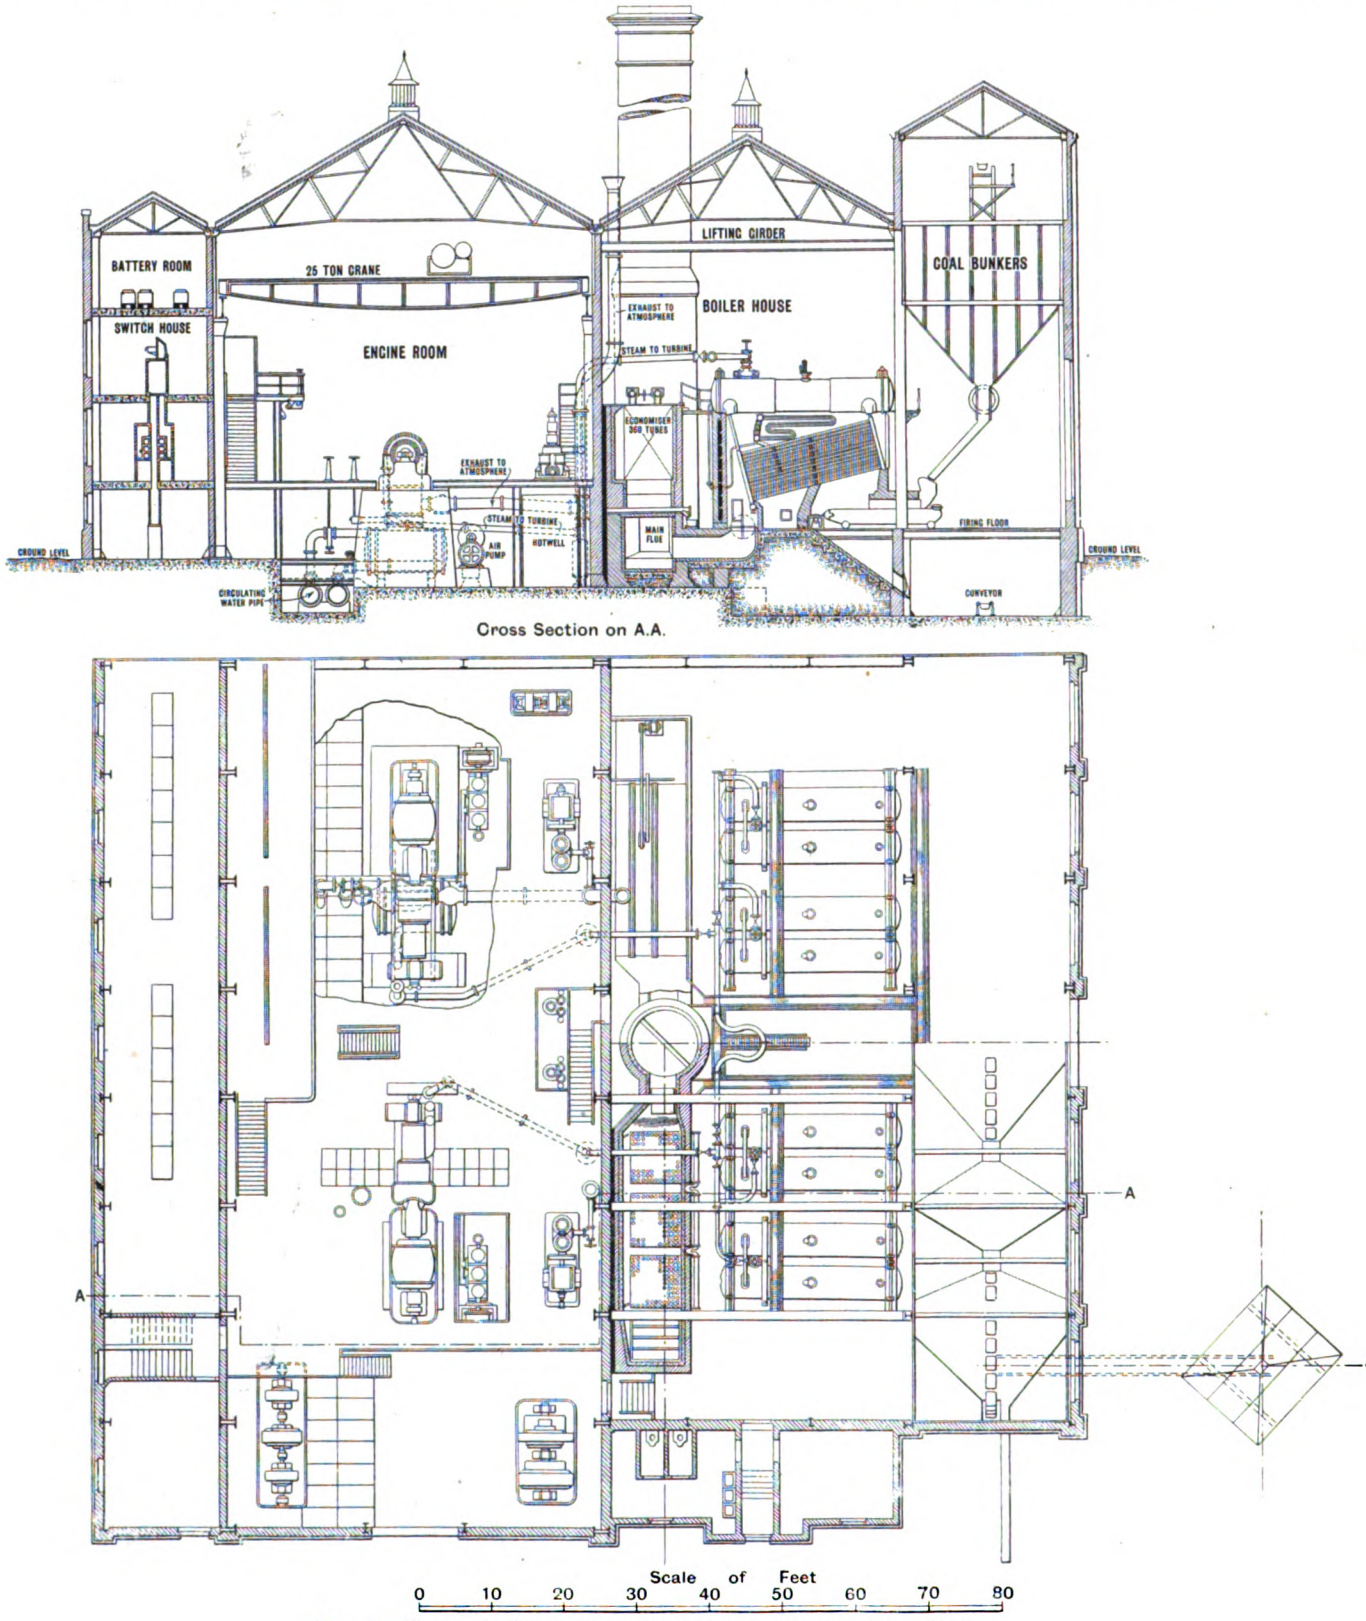

FIG. 1.—PLAN AND CROSS SECTION OF NEW POWER STATION, DUNDEE.

Digitized by Google

In reference to chimneys generally, the great importance of a smooth interior is often lost sight of.

Types of Plant.—Being anxious to put in most up-to-date plant, and attain the best possible results in the supply of cheap power, the author was very desirous of using gas engines in connection with a new power station, and with much optimism made most detailed and careful inquiries from owners and engineers who were using such engines of modern types. Some six months were spent over this work, as answers had in many cases to be got from abroad. The inquiries were limited to the larger units and latest installations. The results were extremely disappointing, in that, by a large majority, opinions were unfavourable, principally on the grounds of unreliability, cost of upkeep, space occupied, first cost, and the inability to meet sudden overloads of short duration. This being so, the question was reduced to the consideration of the reciprocating steam engine *versus* the steam turbine.

On inquiry there seemed to be no doubt as to the superior efficiency of the steam turbine, but in view of the common accusations of high cost of upkeep and liability to breakdown, visits were made to several turbine plants in the country, and the result was distinctly in favour of the turbine on all points, and as regards reliability, the vertical impulse type was equal, if not superior, to the horizontal reaction type. One noticeable thing in all stations where both reciprocating and turbine plants were installed, was the fact that the turbines were running and doing the brunt of the work and the reciprocating plant, where possible, was standing idle. This was by no means due to any difficulty in stopping and starting the turbines, but entirely to their superior efficiency and lower repairs cost.

Generation of Steam.—In comparing the Lancashire boiler with the water-tube boiler, it appears, in the author's opinion, to fall behind the latter for the following reasons :—

First cost (taking into consideration the ample economiser plant necessary for equal economy).

Space occupied and cost of such space.

The extreme difficulty of making a good boiler-house arrangement of Lancashire boilers to fit in with a good engine-room lay-out of steam turbines.

Inferior combustion chamber giving less control over the smoke problem and limitations in the choice of mechanical stoker.

More inefficient complicated and expensive arrangement of piping, partly owing to the larger number of units required.

Before deciding the working pressure, the peculiarities of the type of turbine must be taken into consideration. Speaking generally for reaction turbines, a commercially high and quite successful efficiency is obtained with working pressure of from 160 to 200 lbs. per square inch, with a minimum of practical difficulties. As regards superheat, however, the author is of opinion that in order to avoid any working difficulties and secure at the same time a maximum reliable efficiency the amount of superheat should be that necessary to attain a working temperature of 550° degrees F. It is quite true that tests indicate a superior steam efficiency at higher degrees of superheat, but it is not at all certain whether in practice the total commercial result would show a similar improvement.

While the efficiency of the separately fired superheater is undoubtedly lower than that of a combined superheater, yet it has a great advantage in the possibility it holds out of maintaining a regular superheat at all loads. This is neutralised by the extra space, attention required, and multiplication of pipes and valves.

Economisers.—The development of the water-tube boiler has undoubtedly rendered the installation of these valuable adjuncts of less importance, and in particular where cheap coal is being used they have a difficulty in justifying their extra cost. At the same time, the author recognises that in connection with turbine plants, where the condensed water is at such a low temperature, they have their uses in protecting the boilers from the well-known bad effects of a cold feed. Under ordinary circumstances economisers should be put in and careful attention given to their position and size to give the best results from the commercial rather than the strictly technical point of view.

Brickwork Settings.—The settings both in detail and arrangement do not always receive that strict attention which is their due. So far as their arrangement is concerned, the principal rule to follow is to design the settings as compact, stable, and accessible as possible, and to shorten the lengths of all flues and passages to an irreducible minimum, giving good, sweeping, smooth curves at every change in area or direction. Much trouble has been caused when the flues have been roofed with brick arches by the expansion and contraction of the latter, causing the side walls to bulge, loosening the brickwork, and sometimes causing the collapse of the lining. Heavy T-irons and cast-iron plates get over this difficulty, besides providing a smoother surface. Although the loss by radiation appears comparatively small in ordinary boiler tests, it must be borne in mind that such tests are usually made at or near full load, and that, therefore, a constant loss like that of radiation assumes a much greater importance in the practical case of an ordinary generating station, where the boilers are often the reverse of fully loaded for the greater part of the time. Two practical devices suggest themselves in this connection; one is to build the settings with hollow walls, packing the cavities with a suitable non-conducting substance, and another to face the outside with glazed bricks. As an example of loss of temperature that may take place due to the above causes the author may mention a case with which he is well acquainted. The economiser is separated from the boilers by a flue about 50 ft. long, and although the brickwork of the latter is in good condition, there is a difference in temperature of the gases in this flue measured at two points 43 ft. apart of 100° Fahr.

Built-in fittings, particularly dampers, must be carefully designed with a view to freedom from sticking in working, due either to their position, settling of brickwork, expansion or contraction. Instead of being as rough as they often are, they should be most carefully fitted. Arrangements should be made to stop the leakage usually considered inseparable from dampers. The best cure for this is the use of butterfly dampers. Expansion being a considerable factor in such fittings, sufficient clearance must be left to ensure easy working when the boilers are being forced, as the inability to open or close a damper may have very serious effects.

The bricklaying should be done by men experienced in the construction of furnaces, because the requirements are not the same as for ordinary building. In all cases the joints should be as close as possible, and the cutting of bricks should be avoided. Where it is absolutely necessary, as, for example, the closing of an arch, the cut surface of the brick should be rubbed smooth to ensure a close joint. Great care should be taken to render all surfaces smooth, as the effect of rough surfaces on the draught are often under-estimated, and as far as the furnace is concerned, careless laying militates against durability under the effect of the fires. Certain schemes of reinforcing the brickwork by means of steel network in the joints, &c., are in the market, and there is much to be said for their consideration.

Draught.—The question of mechanical *versus* natural draught is likely to remain an unsettled one. If forced draught means brutal treatment of a boiler by forcing a supply of air for overworking an undersized combustion chamber, then the author would have none of it, but would substitute, for consideration against induced draught, a system of moderate pressure supply designed to control the air for combustion to a boiler within the limits of efficiency, and without deteriorating effects. In considering such a pressure draught, it is assumed that the air is supplied to a closed ash-pit, and that the pressure above the fire is equal to or very slightly below that of the surrounding air. The difference of pressure necessary to overcome the resistance of the boiler flues and economiser would then be provided by a comparatively short chimney. It is submitted that the pressure draught is superior for the following reasons :—In case of any leaks in the settings, the efficiency of the draught will be preserved, and as the difference in gas pressure between the interior of the flues, &c., and the surrounding air is much less, harmful air leakages will be avoided. If the quality of the coal is such as to require frequent opening of the fire-doors to break up clinkers, &c., the inrush of cold air, with consequent loss of efficiency and damage to brickwork and boiler will be avoided. The size and consequent price of the plant is smaller. This, of course, may be a disadvantage from the fan-maker's point of view.

Speaking generally of draught, the installation of a chimney of a capacity sufficient to deal with the normal full load of the plant is recommended, because this method is, after all, the most efficient, simple, and reliable, and appears to be cheaper in first cost. It should be understood that the author is not condemning the use of mechanical draught for all circumstances; the above recommendation only refers to the normal conditions while a power station is going easily. During the erection of extensions nearly all power stations are pressed; therefore, it is recommended that everything should be constructionally ready for the installation of a pressure or induced draught, not in recognition of the superior economy of such apparatus, but in appreciation of their temporary utility in producing a desirable margin of power.

Coal Handling Plant.—It is only after a power station has attained considerable size that any superiority in the mechanical or automatic handling of coal is made manifest. The most ideal conditions prevail in few towns, viz., the high-level railway where a trestle-supported siding can be run in at a higher level than the overhead bunkers. With the railway at the same

Digitized by Google

level as the firing floor, the first questions to consider are the methods of filling the feed-hopper, and the position of the latter relative to the necessary conveyor. A not uncommon difficulty in made up ground is the limited depth to which one may go with the hopper. If the required depth is likely to be below the water-level, it is desirable to sink a watertight cast-iron tank lined with concrete. As to the means of emptying the waggons, there are four methods available, viz., by hand, bottom door emptying, end tipping, and side tipping. The choice between the last three necessarily depends upon the type of waggons available and the speed of service. The author's opinion favours the bucket type of conveyor, in spite of its considerably higher cost for the following reasons :—Longer life, neater and cleaner work, less wear and tear, less power used, less noise, increased reliability, less breakage of coal; in short, less total cost in working.

Although steel bunkers are convenient, light, and in more general use, yet a case is clearly made out for the serious consideration of reinforced concrete. An estimate of the probable saving in cost obtained from four known cases approximates 25 per cent. for equal capacities. In designing the bunkers, special attention should be given to the arrangement of the compartments with a view to storing different classes of coal to be easily drawn from by the engineers at their discretion.

furnace doors and front. This results in considerable damage by overheating, and is liable to set the coal in the hoppers on fire. Sticking and breakage of dumping bars and rods in some types due to overheating from ash accumulation is extremely awkward at times and not unusual. The cost of renewing the brick arches may become excessive unless they are constructed with unusual care. In some types clinkers will not ride over the dumping bars, but accumulate on the grate, reducing the effective area of the latter, and causing a drop in the steam pressure. In such types, also, the dumping bars give trouble by getting displaced and burning away.

Ash and Soot Handling Arrangements.—These should be designed so as to keep ash and soot out of, and away from, the boiler-house proper. The ash basement under the boilers or firing floor is the proper place for dealing with such refuse, and it is quite simple to load it into the conveyor, with a minimum amount of scattering or dust. The cleaning of the economisers ought to be arranged for in the same way, giving easy connection with the conveyor. In the new station designed by the author, an economiser arrangement was adopted which was intended for use with very small cheap coal. Specially designed screw conveyors are fitted in sloping-sided compartments, forming the floor of the economiser chamber. This will prevent the annoyance of shutting and cooling down of the economisers

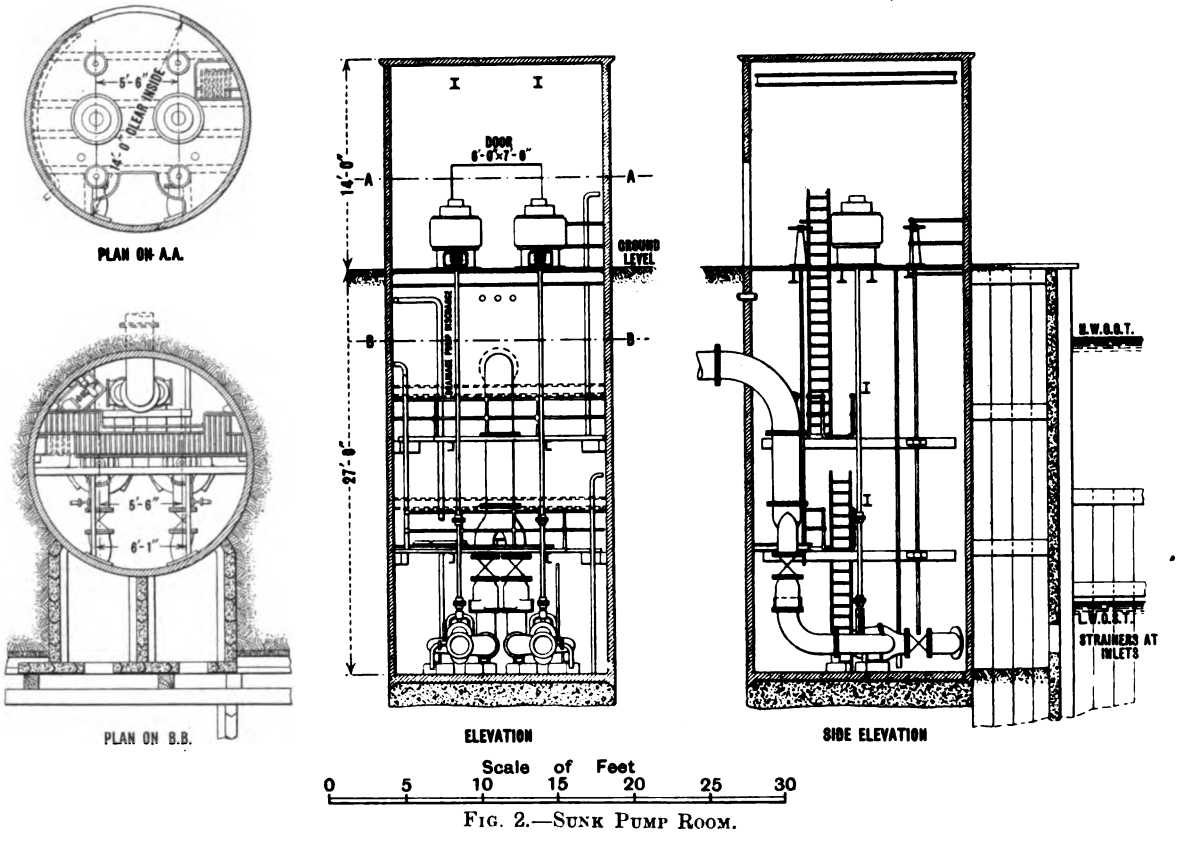

FIG. 2.—SUNK PUMP ROOM.

As regards the measuring of coal, the conflicting results obtained where the weighing system is in vogue, and the impossibility of tallying, however accurate the machines, decide in favour of the volumetric measuring as against weight measurement. This only refers to boiler-house measurement, and not to the measurement of coal supplied to the station, which, of course, must be weighed.

Mechanical Stokers.—So far as use with water-tube boilers is concerned, the author favours chain-grate close-linked stokers in spite of the following disadvantages :—Clinkers are very apt to adhere to the brickwork at the sides of the grate, and these scrape off the fire at the edges leaving the bars exposed. The act of breaking away these clinkers does considerable damage to the brickwork. The wear on the worms and worm-wheels is sometimes very severe, due to distortion of the whole grate, which takes place after a time and causes the gear to work very stiffly. This trouble is aggravated by the difficulty of keeping the working parts lubricated when working the stoker slowly with the dampers nearly shut, owing to the rise in temperature of these parts. The split cotters in the pins of the grates come out, the pins then work their way out, and jamb, generally somewhere at the back. If an attempt is made to deal with a very light load by reducing the air supply, it is found that the fire will ignite right back to the

for the necessary frequent cleaning, and will result in a considerable saving of labour.

Feed Pumps.—It would seem that where a pump is to work at a full-load rate for long periods the superior efficiency of the electrically-driven pump would point to its adoption. Such pumps, however, do not lend themselves easily and economically to regulation over wide ranges, and this combined with their appreciably higher first cost militates against their use under conditions of variable loads. It is necessary in any case to instal one steam-driven feed pump, at least, in a generating station for use in emergencies when electrical power is not available. Probably the best policy to follow is to start the first instalment of plant in a station with steam pumps and use electrically-driven pumps for the extensions. Although feed pumps are more frequently located in the boiler-house, there is a great deal to be said for situating them in the engine-room. The arrangement of feed-piping can often be simplified and made more direct, and the pumps are likely to receive more attention than they would get at the hands of the firemen. It is important in such cases to arrange for convenient regulation from the boiler-house.

Engine-room Lay-out.—In dealing with the lay-out of the engine-room with turbine plant of the horizontal type, the first thing is to decide whether the axis of the turbines shall be

Digitized by Google

parallel to the length of the engine-room or across it. With the larger sizes of turbines of 1,500 kw. and above, and a single row of boilers parallel to the engine-room, considerable space can be saved by the first arrangement. Before taking the utmost advantage of this, however, it is well to forecast future possibilities in the way of other types of plant, such as vertical turbines, gas engines, &c., as the span and height of the crane may otherwise greatly handicap the choice of plant required for extensions. The condensers can either be placed lengthwise with the turbines, or across; the former gives a very compact arrangement with the turbines along the length of the engine-room. In condensers of the *contra-flo* type, however, the steam inlets are situated eccentrically, and such condensers must therefore be placed across the turbine.

With regard to the air-pumps, there are two or three modifications to choose from, viz., the simple air-pump or two separate pumps, one for dealing with air and vapour, the other for the water, or, thirdly, a vacuum augmentor in combination with the air-pump. The absolute pressures attainable respectively

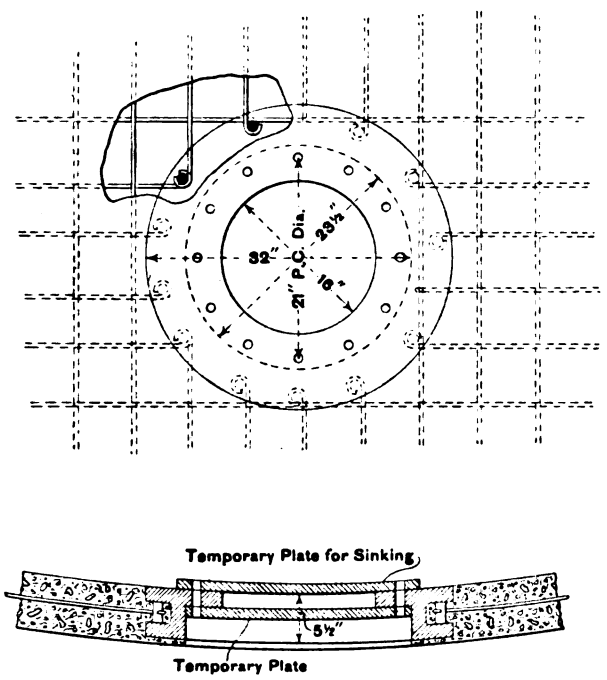

FIG. 3.—DETAIL OF SUCTION INLETS TO PUMP ROOM.

in the condenser decrease in the above order, the extra complications being intended to increase the density of the air and vapour before it is dealt with by the air-pump, which is done by cooling in the one case and by a preliminary compression with a steam-jet pump in the other. The practical advantage of the possible increase in vacuum by the use of such methods is rather doubtful, except, perhaps, in the case where the available amount of cooling water is limited and its temperature is high. It will also be found that this apparatus requires to be below the level of the condenser, and that the necessary depth cannot always be given owing to complications of sewers and liability of flooding. Facilities for the cleaning and replacement of tubes should not be lost sight of in the design.

Circulating Water-pipe System.—To reduce the power required for pumping the circulating water to a minimum, the outlet end of the discharge pipe should be below the level of the source of supply, so that the arrangement forms a species of syphon. Precautions are necessary to deal with air liberated from the water or leaking in at joints, if the top of the syphon is far above water level, otherwise the syphonic action will soon cease. The advantage of the syphonic effect is, of course, limited to about 30 ft. (practically it may be found to be much less), and in cases where the water has to be raised to a considerable height, the recovery of power rendered possible by the use of turbines situated near the lower end of the discharge pipe, and driven by the water on its return merits consideration. Every care should be taken in the laying and jointing of the pipes, and the latter should be specially protected from corrosion if the ground is bad. Trouble has been experienced in cases where cast-iron pipes have been embedded in solid concrete with breakage, due, probably, to expansion and contraction with the varying temperatures of the discharge water. A form of pipe which possesses considerable advantages for this work is one constructed of reinforced concrete. Such pipes are cheap and durable, and can be moulded practically in any desired shape. In any case, substantial foundation must be provided for the pipes to obviate subsidence, and if the ground is soft, piling becomes necessary.

It being necessary in the case of a pump-room which the author is at present constructing, to sink a large vertical reinforced concrete cylinder for use as a pump chamber to a depth of 30 ft., the difficulty of making the suction pipe openings below water level was overcome in the manner shown in Fig. 2, which may be of interest. The method there shown has been tried before in similar work below the water level, and found perfectly satisfactory. It also does not interfere with the sinking of the chamber in the way branch pipes would do.

Main Steam and Feed Piping.—The simplification and reduction of the amount of steam piping has its effects on the coal bill, while the reduction in the number of valves and joints is correspondingly beneficial in economy of maintenance. Although steam traps may possibly work correctly for a few hours or days, yet experience shows that they cannot be relied upon (without constant adjustment and overhaul) to prevent waste of steam on the one hand, and accumulation of water on the other. The diameter of the main steam pipes can advantageously be reduced when used for superheated steam. When turbines are used there are additional reasons, as the flow of steam is more uniform, and the retention of temperature of superheat is of greater importance than a slight reduction in steam pressure.

Generators.—The question of efficient ventilation has risen into great prominence since the advent of the turbo-generator, and ducts are generally formed in the concrete foundations for this purpose. If possible, it should be arranged that these ducts lead from a cool space in which the air is still, dry, free from oily matter, and has had time to deposit some of its dust.

Auxiliaries.—The use throughout a generating plant of continuous-current motors for driving auxiliaries is recommended in cases where direct current is to be distributed in the locality of the generating station, as it is very convenient to have a storage battery reserve for this class of work, and economical adjustment of speed has advantages.

Switchgear.—In moderate and large-sized stations the best system is to isolate the whole of the high-tension gear in special chambers, operation being effected from a gallery overlooking the engine-room through the medium of electrical control. The cellular type of board is to be preferred, and as much space as can be afforded should be allowed for the gear. This is a strong reason for arranging the switch chambers along the side of the engine-room, rather than across the end; besides, this method allows of some simplification in the connecting cables. The busbars should be divided by means of section switches, so that any part may be made dead for inspection or repair without interference with the supply. Too much thought cannot be bestowed in obtaining a safe working arrangement. In a system which is being carried out by the author the doors of the compartments containing the feeder isolating switches are provided with double locks. One key will be kept by the station department and one by the mains department. Whenever any cable is required to be disconnected for testing or repair, the isolating switch will be opened and the compartment locked by both parties. The cable then cannot be made alive again except in the presence of both the departments concerned. Facilities for earthing parts of the gear should be provided as a safeguard against their becoming charged by leakage or otherwise, while persons are working on them. It is almost universally acknowledged that oil-break switches are the only type that should be used for breaking high-tension circuits, and their breaking capacity should be chosen with reference to the total K.V.A. capacity of the station on a momentary short circuit.

DISCUSSION.

Mr. S. L. PEARCE (Chief Electrical Engineer, Manchester) dealt first with the driving of piles. The author had stated that a safe load of 60 tons might well be allowed on any well-constructed reinforced concrete pile, but figures of the section had not been mentioned, so that they were left a little bit in the dark as to the basis on which this load had been reckoned. He should imagine a section of about 14 or 15 square inches. With regard to the method of driving the piles, he thought that a weight of three tons with a three-foot fall gave about 41 or 42 tons force, which was not excessive if the supporting power of the pile was to be reckoned on the basis of 60 tons. He believed it was an accepted fact that a heavy monkey with a short fall did less damage than a light monkey with a long drop. If a long-continued pressure could be applied to these piles they could get very much better results. There were some interesting remarks in the Paper with regard to using reinforced concrete as a suitable material for chimneys, but he thought that 1,500° F. was altogether too high a temperature to which this material should be subjected without a suitable lining. Two reports had been issued fairly recently, one by the British

Digitized by Google

Fire Prevention Committee and one by a committee which investigated the results of high temperature upon reinforced concrete work at San Francisco after the disastrous earthquake and fire, and he thought it was proved pretty conclusively that Portland cement began to lose its water of crystallisation at from 600 to 800° F., and therefore when reinforced concrete was subjected to an excessive temperature the concrete began to crumble, and the structure, he should imagine, would become absolutely unsafe unless a lining or inner ring of some material was used inside the reinforced concrete chimney. Dealing with the question of gas-engine plants which the author had dealt with at some length, the criticisms he had to make, he said, had been somewhat disarmed by a remark made by the author in reading the Paper, that his inquiries had only been directed in those quarters where the gas was produced on the premises. He took it the author meant producer gas, and if that was the case he ventured to think that the unsatisfactory nature of his replies was due more to the producer end than the gas-engine end. At the commencement of this year, through the kindness of Mr. Leonard Andrews and other engineers interested in large gas-engine plants, he was able to make a visit to the Continent and see several of the largest gas-engine plants of different makers, the Nuremberg, Cockerill, Körting, and Ehrhardt-Sehmer, and although he went somewhat biassed by the experiences at Johannesburg, he had returned in a somewhat different frame of mind; for the experiences and facts he had been able to get first-hand had convinced him, at any rate, that the gas engine had certainly a future in this country. Undoubtedly very considerable progress had been made in Germany, and it had been made in those countries where they could use the blast-furnace or coke-oven gas as a bye-product for the fuel of the gas plant installed; but whether the gas engine was used on town gas or coke-oven gas or producer gas or blast-furnace gas, there was no very great difference in the engine. All the first-class makers were prepared to build gas engines and guarantee them to work with all these forms of gas, and therefore he thought it was the producer end that really dominated the situation to-day. There were very few examples on the Continent of producers; there were a few using anthracite coal and still fewer using bituminous coal. The single-tandem engine seemed to be most in favour, but there were some very good examples of twin-tandem engines also to be seen. As to size, engines could be seen up to 2,500 horse-power, but this was about the limit where the work was divided between two cylinders, and gas-engine designers appeared to be agreed that the limit of power that could be got from a single-cylinder gas engine was in the neighbourhood of 1,400 effective horse-power. Therefore the twin-tandem type was the only one by which a higher capacity could be obtained, running up to 5,000 or 6,000 h.p. Such a gas engine would permit the use of electrical units of about 4,000 kilowatts, and there was at any rate one firm—probably there were more on the Continent—which was prepared to build these units to-day. The reason that they had not been built hitherto was that they had never been asked for. 3,500 h.p. seemed to be about the limit for works on the Continent, and that was where the gas engine had found its sphere of usefulness up to the present time. With regard to Mr. Richardson's objections, these must be admitted so far as the space occupied was concerned, and the inability to meet sudden overloads of short duration. As to capital cost, the author had stated that the generator and gas engine and producer was about 25 per cent. to 30 per cent. in excess of the reciprocating type, and, of course, the capital cost would be proportionately greater when using steam-turbine units. The same remarks applied to the space occupied. One maker was prepared to build a 4,000 kilowatt gas-engine set to take up 2,600 sq. ft. of space, and, comparing that with a 4,000 kilowatt turbo unit, the floor space in the latter case was about 400 sq. ft., roughly six to one in favour of the steam turbine. Weight was also in favour of the steam turbine; the weight of half the frame of a large gas engine was in the neighbourhood of 70 tons. This was an enormous mass, and there seemed to be very little chance of getting down the initial cost of gas engines in the future for this reason. With regard to reliability and upkeep, he was not quite in agreement with the author, because he found on investigation into the best examples of gas-engine plants on the Continent that there was not much to choose between the upkeep and maintenance of gas-engine plants as compared with reciprocating plants. In contrasting the advantages and disadvantages of gas-engine generating sets and steam-driven sets, it was not necessary to remind them of the great advantages of using gas plants in the shape of saving fuel consumption. Many of them had read Mr. Highfield's evidence before the London Power Bill's Committee,* and he did not think Mr. Highfield had overstated the case when he said that the best figure for steam plant was 2·75 lb. of coal per unit and for gas plant about 1·75 lb. He would like to make one reference to the advantage that had accrued in one particular works on the Continent, viz., the Cockerill Company's own works, where they had last year an output of 24,000,000 units, and the cost at the station per unit generated, including capital charges, was one-sixth of a penny. There was therefore a fair margin for fuel cost before they came anywhere near the best cost obtained with steam plants to-day. This question of gas engines and their possible use in central stations had been brought prominently forward in this country a short time ago, and Mr. Andrews took up the case that good use could be made of gas-engine plants in combination with the existing steam units, the idea being that the gas engine could be put to run on a steady load, leaving the steam turbines to deal with the peaks. He had looked into the matter from this point of view as regards Manchester. Their night load at Manchester averaged about 3,500 kilowatts, and therefore it was perfectly obvious that they could put in one or two gas engines and keep them running the whole 24 hours, leaving the rest to the steam turbine and reciprocating plant, and very substantial economies could be shown, despite the objections and disadvantages which the author mentioned. On the question of the steam pressure for turbines, with the so-called reaction type there was absolutely no advantage from the steam-consumption point of view of using 200 lb. as against 160 lb.; tests made some time ago on a 3,000 kw. Parsons-Brown Boveri set showed that at full loads there was only 5 per cent. decrease in steam consumption, at half load no economy could be shown for increased steam pressure, and at no load the steam consumption was greater than with the lower pressure. He disagreed with the author that a working temperature of 550° F. was a fair figure for the reaction type. It was altogether too high, and he was inclined to put the limit of superheat to be added to the steam at a maximum of 150°. The bulk of troubles experienced on the Continent with the Parsons type turbine was due to the excessive superheat. In a Paper on "The Influence of Surface-Condensing Plants," read by Mr. Morrison before the Institution of Naval Architects, tests were described which showed that in no type of condenser could the condensing capacity due to its dimensions be maintained, unless the air pump was sufficient to render all the tube surface available for condensing. In other words, they must have an air pump which was perfectly capable of dominating the condenser under all conditions of normal air leakage, and it was a good sign that this latter was now receiving more attention than hitherto. Personally, he preferred two separate pumps, one for dealing with air and vapour, and the other with water. In connection with the ventilation of generators he had adopted the method at Manchester of totally enclosing the alternator, and using an external fan blower with an air filtering apparatus for giving the necessary cooling effect on the machine.* On blowing 21,000 cubic feet of air per min. through the machine, the result was distinctly advantageous. The chief advantages were that they got a machine with a total absence of noise, complete cleanliness, and, therefore, less liability for the insulation to break down. Furthermore, for the same type they had less cost in spite of the extra cost for the blower and air filter, because they could use machines of a smaller rating for a given output, whilst the heating question which would have to be grappled with in the near future was overcome. With regard to auxiliaries, there was a limit for direct current for such purposes in large stations, as it would mean continually adding small generating units or increasing the sub-station plants with corresponding conversion losses, and therefore it was better to instal three-phase motors for the majority of purposes required. On the other hand, he strongly advocated installing a small storage battery for excitation purposes and for operating the trip circuits in connection with automatic relays. In connection with extra high tension switchgear, he was wholly at one with the author when he stated that the breakage capacity of switches should be adjusted in reference to the total K.V.A. capacity of the station that might be dealt with at any moment. It was becoming clearly recognised to-day that the capacity of the smallest oil switch must be the same as the largest.

Mr. LEONARD ANDREWS (Key Engineering Co.) confined his remarks to the gas engine question, although he complained that Mr. Richardson had rather knocked the bottom out of some of his arguments by saying that the remarks in the Paper applied only to producer gas stations, but he still thought it possible that he might be able to make one or two remarks that would be of interest. He entirely endorsed what Mr. Pearce had said: that the capital cost of gas engines was, and probably would always be, greater than steam turbines. At the present time it was correct to put this at about 25 per cent. greater; Mr. Pearce had put it at 25 per cent. greater than reciprocating engines, but he personally thought it was almost this amount greater than steam-turbine plant. Against that, however, there was a very big saving in the fuel consumption. Mr. Highfield's estimate of coal consumption, given before the London Power Bill Committee, was also about correct. Recently he had had the opportunity of seeing several gas-engine sets, which showed the figure of 1·75 lb. of coal as being on the high side. As to overload capacity, of course, the gas engine would probably never compare with the steam turbine, but a great deal of the bad repute respecting the lack of overload capacity of the gas engine had really arisen from the fact that its capital cost was high and the gas-engine makers had been inclined to overrate their plant. Gas-engine makers were now realising that this was a mistake, and were now rating their plant somewhat lower. A few days ago he had some particulars given him of a plant

* *Electrical Engineering*, Vol. III, p. 939.

Digitized by Google

in this country working on producers, which had a normal capacity of 820 kilowatts, but, owing to a breakdown on some other plant, the gas plant was called upon to carry a load of 950 kilowatts, and had done so quite easily for two hours. Of course, this was nothing like what the steam turbine would do in the way of overload, but it was about the highest that could be got out of the generator. This particular instance was 17 per cent. overload for two hours, and it was as much as they had been accustomed to expect before the days of the steam turbine. Against the argument that gas engines were still unreliable, he had collected figures which showed that the users of them placed frequent repeat orders. He found, for instance, that one firm which had turned out about 69,000 h.p. up to the present had received something like 40,000 h.p., or 60 per cent. in repeat orders. He thought they would find the idea which existed about the unreliability of the producer end would disappear in exactly the same way as had the idea that the gas engine was unreliable. There were some large producer installations in this country which had been running quite satisfactorily for years.

Mr. C. E. C. SHAWFIELD (Chief Electrical Engineer, Wolverhampton) said that he had found the cost of a steel chimney to be about one-third that of a brick chimney, but he would be chary of making the experiment of using a concrete chimney. He had noticed in the American technical Press a description of several accidents with chimneys of this description, and this appeared to be due to the fact that the strength of the concrete after mixing depended on the length of time which elapsed between the mixing and its final placing in position. Consequently, if the concrete had to be mixed on the ground, as was very often the case, the time that elapsed was longer the higher the chimney got, and he had noticed that in nearly all cases the failure of these chimneys had taken place at about the same total height from the ground, and that in each case it had been attributed to the fact that the concrete had stood just a few minutes too long before being formed. In an ordinary reinforced structure of ordinary height this difficulty would not occur, but in the case of a chimney, say, 200 ft. high, it was a consideration that should be taken seriously into account. Neither Mr. Pearce nor Mr. Andrews, in stating that the actual consumption of fuel for a gas plant was 1·75 lb. per unit and for steam plant 2·75 lb. per unit, had given much information, as it was quite possible that a steam plant using 4 lb. of coal produced its energy with a lower fuel cost than the gas engine using 1¾ lb. It depended on the class of coal and the price that had to be paid for it.

Mr. ANDREWS: Both Mr. Highfield and myself meant the same quality coal, viz., bituminous slack.

Mr. SHAWFIELD, continuing, said there was another question which had not been emphasised quite sufficiently by other speakers, viz., the vast difference between steam turbines and gas engines in the matter of overload. At the present time it was practically possible to couple a 1,000-kw. turbine on to a 2,000-kw. generator, making a 2,000-kw. unit. In the case of the gas engine, however, the total capacity of the plant appeared to be absolutely limited by the engine itself, and he had not been able to obtain a guarantee of more than 15 per cent. overload—and that only for a very short period—from any maker of gas engines, say, of 1,000-h.p. size. On the total cost of a station, therefore, it meant that the proportion of spare plant had to be normally greater for gas than for steam. With reference to the question of the influence of steam pressure on steam economy, he quite confirmed the figures given by Mr. Pearce, as he had found the reaction turbines which he had recently installed were actually more efficient throughout the whole range of load at 135 lb. pressure than at the 165 lb. pressure for which they were designed. He had experimented a good deal with both induced draught and forced draught, and had found forced draught to be in all cases distinctly less economical than induced. He thought the explanation of this was to be found in the fact that with positive pressure below the fire they also got a positive pressure above the fire, and, secondly, the air supply was limited to that which passed through the fire bars. When dealing with bituminous coal, it appeared to be absolutely necessary, in order to obtain the highest economy of working, that a certain amount of air should be admitted over the top of the fire, as otherwise a considerable amount of the unconsumed gas tended to pass away through the tubes. He had found that this occurred not with one class of boiler or stoker, but with three types of stoker and three types of boiler. In dealing with soot- and ash-handling arrangements Mr. Richardson had advocated an ingenious arrangement for dealing with the dust and dirt accumulating in the boiler flues and in the bottom of the economiser chamber. He was afraid, however, that the cost of this would hardly be justified by the total saving. It had occurred to him that a quite feasible and much cheaper way of dealing with the accumulation of ashes and soot in economiser tubes would be to instal along the line of the tubes, say, a 3-in. pipe connected to a vacuum chamber something on the general lines of the vacuum cleaner. He had experimented in a small direction with such apparatus, and had found the results hopeful. If it could be done, the first cost of the apparatus was really very small. There was one remark he would like to make with regard to feed pumps, and that was that Mr. Richardson had omitted to mention what was probably the most convenient and economical system of the present day, and that was the "Roturbo" centrifugal pump. He was aware that this had only recently been available, but he could assure them that after about eight or nine months' experience of it, in comparison with any other form of reciprocating pump it was a luxury.

Mr. A. T. YATES (Swinton and Pendlebury Electricity Committee, and of Matthews & Yates, Ltd.) said that, in his opinion, induced draught was more efficient in producing the greatest evaporation at the least expenditure in fuel than chimney draught. The reason was that by working at a high-water gauge a higher furnace temperature could be obtained, and therefore much more rapid evaporation took place. It was a fact quite well known that the highest calorific value in the coal was not obtained in the highest-priced coals, and that low-grade coals sometimes had a higher calorific value than the more expensive ones, and induced draught enabled this cheaper coal to be burned with economy; so that even if they had to burn a very much larger weight of coal for a smaller duty, they could burn coal of a very much cheaper quality and get more efficient work out of it. It had been proved in many tests that induced draught plant had paid for itself in the first year of its installation. The speaker also referred to the value of induced draught for meeting sudden fog loads. When everything was taken into consideration, he was perfectly satisfied they would find the first cost of a natural draught installation to be two or three times that of the installation of boilers with a smaller chimney sufficient to carry the smoke far enough from the surroundings in conjunction with the induced draught plant. The induced draught plant was also very advantageous in reducing the large amount of black smoke that was put into the atmosphere by many chimneys.

Mr. W. H. SEATON (British Westinghouse Company) said the first thing referred to in the Paper was the proper location of the site, and this was a question which worried him a good deal. In England it seemed to be the one idea to get on the side of a small stagnant canal, and if there were two or three cotton mills turning their condensing water into it, it seemed to be regarded as an additional advantage. On the question of distribution there seemed to be tremendous ignorance. He met a lot of power-company engineers, for whom he was always sorry, because he thought there were only two possibilities about them: one was that they might be able to generate at a farthing, and the other was that they might be able to sell at a half-penny. Obviously this left no margin for distribution. On the other hand, when he had received bills for electricity which seemed extravagant, and had gone to the town hall and asked for an explanation, he was told that distribution costs were a very serious matter indeed. Coming to gas engines, he said that many iron and steel works were sticking to steam absolutely, as there was in some cases a fear that gas engines might create an element of uncertainty in carrying out orders promptly to time. He agreed with Mr. Pearce when he stated that with the Parsons type of turbine 150° of superheat was amply sufficient. He had worked at higher degrees of superheat, and had very good reason to regret it. It was difficult to get proper control over the superheat, and he had had a particular case where he was guaranteed a total temperature of 550°, and the actual temperature varied from 400° to 700°. The consumption of coal per kilowatt-hour had been put at 1·75 lb. for gas engines, and at 2·75 lb. for the steam turbine. He would like to emphasise that this possible one pound of coal per kilowatt-hour saving was all that they could possibly say in favour of the gas engine, although he had known men who had tried to say a good deal less. He knew of cases where the oil bill was largely wiping out the coal saving.

Mr. C. TURNBULL (Chief Electrical Engineer, Tynemouth) spoke of a small producer gas installation in which the effect of the gas on the copper was such that the commutators were all black, and the 'bus-bars had the appearance of being lamp-blacked. The insulation broke down continuously, and the result was that everything was in an exceedingly bad state. He had heard that at Johannesburg they had had some trouble with the insulation, and if anybody present was going in for gas engines he would very strongly recommend them to get guarantees that the gas would not effect the insulation, because in several of these cases it had been a very serious matter. He also asked Mr. Richardson whether he himself would put in a reinforced concrete chimney. The question of upkeep was important with regard to reinforced concrete for bunkers, and he did not think ferro-concrete bunkers would do.

Mr. A. C. CRAMB (Chief Electrical Engineer, Croydon) remarked that a great deal had been said in favour of gas by one or two speakers, and it would almost appear that there was something behind it when a man like Mr. Pearce went whole-heartedly for gas engines. But would Mr. Pearce go in for a 4,000-kilowatt gas engine plant? Reference had been made to the gas engine scheme mentioned before the Parliamentary Committee by the London Electric Supply Companies, but neither Mr. Parshall nor Mr. Hammond nor any of those present attached very much importance to it, and everybody had a very poor opinion of the proposed station being satisfactory.

Mr. H. R. BURNETT (Chief Electrical Engineer, Barrow-in-Furness) said he had had a great deal of trouble in maintaining

Digitized by Google

fire-brick arches and the walls of water-tube boilers with chain grates. His experience had been that frequently the arches did not last more than a couple of months. He also confirmed the author's remarks on the trouble due to the breakage of dumping-bars.

Mr. C. O. MILTON (Chief Electrical Engineer, Maidenhead), referring to gas engines, said that most of the remarks had been directed to forms of very large gas engines, but he would be glad to have some information with regard to the working of smaller gas engines, say of 150 or 200 horse-power. In many small stations there existed a day load which was of sufficient dimensions to make it economical to run a gas engine rather than to put in a battery, but not sufficiently large for steam-engine plant. He had been thinking of going into the matter himself, but had had a good many hints at this Convention that the producer end was practically hopeless.

Mr. C. C. ATCHISON (Chief Electrical Engineer, Rochdale), speaking on the question of extracting soot from the economiser, said that he had spent six months trying to get out some satisfactory means of doing this, but found that it would take too long to clean out the economiser pit in the manner suggested by Mr. Shawfield. He started off with about a six-inch pipe, and found he wanted a 14-inch pipe to get any suction on at all, and it took about four hours to get an ordinary cartload of soot out. At the same time, when they were dealing with a cheaper class of coal they also had to deal with a large amount of dust, and it was an important point to make the flues easily accessible, not only for men to crawl about and scrape the sides, but also to bring a barrow in and out easily. In putting down some economisers recently he had put in a good-sized door so that the men could wheel the barrow in and out again easily, instead of having to scrape the economiser out in the usual way at the sides. By having a large pit at the entrance of the economiser a very large proportion of the economiser dust settled in the earlier portion of the flue, and it was possible to get it away easily. He wondered if anybody had tried this with Lancashire boilers. In some cases the flues were rather narrow, and it took some time to get inside at one end, and if it could be done by a scraping arrangement so that the dust could be drawn out at the front instead of having to be shifted forward, it would save time. Some few years ago he had had an experience of firing-back in connection with forced draught, and two or three men had been burnt within the period of two or three weeks, but they were able to get over some of their trouble by erecting a locking gear between the fire-doors and the damper arrangements. Mr. Richardson had spoken of corrugated ends to engine-houses, but he had had trouble with the Local Government Board inspector on this point, and had had to put in brick, although he had told the inspector that it would be wiser to have galvanised iron, as the end would have to come down again. He was informed that a loan could not be granted for this, however. On the other hand, in the case of a tramway sub-station, in which borrowing powers had been obtained under a Tramway Act, he had used galvanised iron, and the Board of Trade had granted the loan. He also called attention to the air leakage which took place from the chain holes at the top of the economiser, and he had adopted a method of plugging these up when the scrapers were not in use, which was only for half an hour or an hour at night.

Mr. J. K. BRYDGES (Chief Electrical Engineer, Eastbourne), on the question of air-leakage, said he would like to mention what he believed had been mentioned at previous Conventions, namely, that air-leakage occurred between the sliding dampers and the frames. He had two sliding dampers fitted to Stirling boilers, and when he came to measure up the space he found it was equivalent to the area of a 4-in. pipe leading straight into the flue. This was a serious matter, so he built it up with brickwork above the height of the damper, when it was drawn out, leaving only a small hole for the wire-rope to go through, and in consequence the air-leakage was reduced to a minimum. He asked Mr. Richardson why he lined a cast-iron tank which he had sunk. Was it to weigh it down, or to make it extra water-tight?

Mr. RICHARDSON said it was an outside lining of concrete to keep the cast-iron tank from corrosion.

Mr. BRYDGES, continuing, said Mr. Richardson had also mentioned the superior efficiency of steam turbines over reciprocating engines, but this did not apply so much to smaller units. His reason for running steam turbines was not so much from their superior efficiency as from the fact that in the case of breakdowns he could get a steam turbine at work quicker than a reciprocating engine if he carried out the maker's instructions as to length of time for warming up. He also referred to the underfeed stoker, which he considered had the great advantage over the chain grate that it would burn practically any sized coal; it would burn what was called smudge and duff, and he did not think there was any other chain grate or automatic stoker that would burn this coal satisfactorily. He had also found that the repairs were not as large as they were with other types.

Mr. E. B. VIGNOLES (Chief Electrical Engineer, Grimsby), on the question of foundations, said that Mr. Richardson had mentioned the building of the station on a raft. Although this was successful in some cases, it had very often led to more or less disaster. In one case that he knew of, the raft was built for a building which was not a central station—and when the walls were put up a certain height one corner of the ground under the raft began to give way, as it was softer at that spot, and the whole building tipped over to an angle and had to be entirely pulled down and piles driven in. He thought the question of concrete and ferro concrete piles was one that required careful consideration, and he noticed the other day in going round a large dock site that, although they were using a very large amount of concrete, there were no ferro concrete piles to be seen. They were using timber in all cases and were driving with a small monkey and a long drop. The difficulty with ferro concrete appeared to be the fact that in certain circumstances the concrete opened up, and then there was the liability of wet getting into the concrete and the iron corroding away. He thought that this had been the cause of the failure of several chimneys, viz., that the concrete had been left too long before getting into position, and the iron corroded through wet getting in. They had heard a good deal about gas engines, and wh they had heard absolutely justified Mr. Richardson's conclusion that the gas engine was not a practical thing for generating stations. The author mentioned in one part of the Paper the question of measuring coal in the boiler-house. It seemed to him rather curious to weigh all the coal coming into the station and then measure it volumetrically in the boiler-house. What was the objection to an automatic weigher. He had one in his own station over which the coal was tipped and was automatically weighed, and it worked very satisfactorily. Mr. Richardson gave a very long list of diseases to which the chain-grate stoker appeared to be heir. The whole difficulty was that there were moving parts in the fire, and for this reason he had adopted the underfeed stoker. Repairs on the driving gear were expensive, but he thought he could get over that by driving with a motor. The repairs on the actual portion of the grate in the fire were very small indeed, and he believed that with this type of stoker they could get their repairs down to a minimum and burn practically any kind of coal and get very satisfactory results. When he advertised for tenders for the stoker some of the chain-grate people who were anxious to tender, when they heard of the coal that he was burning at Grimsby, said it was too small and would go through the grate. With regard to Mr. Atchison's remarks on the Local Government Board sanction for galvanised iron buildings, he mentioned the fact that the Local Government Board had sanctioned a loan for a galvanised iron end to the engine-room at Grimsby; the inspector thought it was the most sensible thing to do.

Mr. H. RICHARDSON, who reserved his full reply for the Proceedings, said he would like to make one or two explanatory remarks. Several speakers had mentioned forced draught and pressure draught. His interpretation of the latter was entirely different from that of forced draught. Replying to Mr. Turnbull, he said he was putting in a brick chimney. He was glad that the Paper had elicited an interesting discussion on ferro concrete for piles. He had no doubt, after going very carefully into the matter, as to the infinite superiority of ferro-concrete for the superstructure. He was surprised to hear of any large firm putting in wood piles at all. Although in many cases where the ground was suitable they might have extremely long life, in made up ground the life was not likely to be long.

THE RECONSTRUCTION OF AN ELECTRIC LIGHTING SCHEME WITH OBSERVATIONS ON THE WORKING OF A COMBINED STEAM AND WATER POWER PLANT.

BY C. M. SHAW.
(Chief Electrical Engineer, Worcester.)

Almost every engineer of a supply undertaking has at one time or another had to consider the very important question of the reconstruction or rearrangement of generating plant and mains system connected thereto, especially where such undertakings were laid down in the early nineties. The Worcester electricity supply proves no exception to this rule, and the systems in that city embody features of a highly interesting, engineering, and commercial nature which do not obtain in any other undertakings in this country. There are two sources of prime movers, viz., steam and water power. Two systems of distribution irrespective of traction supply. Two methods of supply, alternating and direct, each having two standard pressures, and finally, two tariff systems with nineteen separate prices for current. The capital expenditure on December 31st, 1905, amounted to £127,385, being £73 per kw. when all water plant was available, or £78 when such plant was useless through flood or drought. The deficit in 1904 and 1905 working after payment of all charges amounted to £1,290 and £298 respectively.

The following plant was in use in 1905:—

POWICK STATION (WATER AND STEAM).

420 kw. capacity driven by steam engines.
120 kw. capacity driven by water turbines.

Digitized by Google

240 kw. capacity driven by water or steam power by means of clutches.
Six water-tube boilers: 10,460 sq. ft. heating surface.

HYLTON ROAD STATION (STEAM).

250 kw. capacity for D.C. supply.
500 kw. capacity for D.C. supply or traction.
70 kw. motor generator coupled to engine by a clutch used for A.C. or D.C. supply.
Three water-tube boilers: 9,420 sq. ft. heating surface.

The author devoted a full year to the close study of the conditions of working the two stations. As the systems at each works are different it was not possible to interwork the supplies, beyond the capacity of the small motor generator at the new works. During the time this data was also being obtained examination was made of practically every power plant in the district, with the result that several antiquated beam engines over sixty years old were found to be still in use. Unfortunately, not one of these users of old age plants could be obtained as consumers for a long period, even though the scale of charges was favourable, which prejudice was traceable to the faulty working of one single A.C. motor many years previously, and to the opposition of a flourishing gas company. The Department had, therefore, to take the initiative. Motors were borrowed from makers and fixed temporarily free of charge, in several works, with the result that a natural demand was eventually fostered.

In due course, the author arrived at a decided opinion that no great improvements could be effected in the cost of generation with the old conditions of working the two stations, though the acquisition of a limited day load was having its effect on the costs. The 1904 works costs, 1·56. per unit sold, on the combined output of the two works was unduly high, having regard to the fact that there was a water-driven plant by which current was generated cheaply, and, further, that the traction output should have assisted in lowering the costs. This high cost was, in a great measure, brought about owing to the heavy expenditure entailed in maintaining a steam plant and staff at Powick, when such plant was, during a great portion of the year, inoperative.

In 1905 the Powick output was 721,000 units, of which 380,000 were generated by water-driven plant. The salaries and wages item for current generated by water turbines should be very low, as few attendants are required. Sufficient men had, however, to be always in attendance to work the whole of the output by steam, owing to the uncertainty of the water supply. Although a full complement of men sufficient to work the steam plant were in attendance daily, it was found to be more economical to shut down the Powick plant entirely during daytime for 1,181 hours, over a period of 180 days during 1905, and 1,332 hours on 150 days during 1906, owing to floods or lack of water, during which time the whole of the A.C. output was dealt with by a small motor-generator at the Hylton Road works.

From the foregoing remarks it will be apparent that the steam plant was worked under very disadvantageous conditions, especially when consideration be given to the fact that no economiser was in use, that the lay-out of works necessitated very long double-steam ranges, also that the extra cost of carting coal 1½ miles beyond the new station was expensive, and, finally, the original steam plant was of old design, and very unsuitable for modern requirements. The author had, therefore, little hesitation in recommending the scrapping of four small boilers, and all the engines, &c., at the old works, and it was decided to dismantle the steam plant at Powick, and concentrate all steam generation at the Hylton Road works.

Previous to the change, two to four boilers had to be worked or kept under banked fires at Powick in case the water power, &c., failed. At Hylton Road one boiler was steamed, and one kept under banked fires, making five to six boilers in commission, whereas under the new conditions of working only three boilers are in use, viz., two steaming, and a third under banked fires.

The rearrangement of staff and workmen for working water plant at Powick and steam plant at Hylton Road has effected economies. The uncertainty of the water supply in times of flood or drought often releases the attendants at the water-power station. During winter, if floods occur, the staff are transferred to the steam station to assist in meeting the heavier call on steam plant. Should a shortage of water occur during summer, these men are particularly useful for assisting with the necessary overhauling of plant.

In preparing the scheme for rearrangement of works, due regard had to be given to the following conditions which obtained at Worcester: (*a*) The heavy capital expenditure already incurred. (*b*) The area of supply, being very large, necessitates a H.T. system. (*c*) The complete system of alternating mains and transformers already supplying outskirts and a portion of the centre of the city. (*d*) The high periodicity of supply (100 periods single-phase) is unsuitable for power purposes. (*e*) The system of D.C. feeders and distributors in the centre of the city and power area.

With the knowledge that most of the local industries were in a settled state with little prospect of any abnormal growth, it was not advisable to carry out any complete change of periodicity, as such was only necessary for a power load. A very extensive single-phase A.C. 100-periods network had already been laid down at heavy cost in residential districts for lighting demand. The area of supply was very extended, and the demand for power negligible, consequently a change over to D.C. with the sacrifice of capital expended on H.T. mains, &c., would not have been justified. It was, however, imperative that the old 100-periods supply be not extended more than possible, as such system might ultimately have to be changed.

New generators, switchboard, mains, &c., of a design easily convertible to 50 periods two-phase were accordingly installed. Fifty-period transformers of standardised capacity are also gradually displacing the original small 100-periods types. A slight percentage in efficiency is so sacrificed by using these transformers, which loss, however, is neutralised by the reduction of open-circuit losses.

In view of the fact that all present demands for power could be dealt with from the existing D.C. station, the following limited scheme was eventually decided upon:—

	£
Extension of engine-room for three generators ...	1,150
Two A.C. steam generators, 350-400 kw.	4,550
Switchgear	200
Mains	260
Contingencies	340
	6,500
Less receipts from sale of old plant	1,650
Net cost	4,850

Much consideration was given to this scheme, and it was eventually adopted. Then the question as to how the cost of the change should be met arose. As it was not possible to meet such a heavy charge out of revenue in one year, steps were taken to obtain sanction to spread the cost over three years. The Local Government Board were communicated with, and they held an unofficial inquiry. The inspector informed us that the Board would probably grant a loan for the full amount of £6,500 if the Council guaranteed the repayment of the outstanding debt of £4,072 on old plant within three years. An official inquiry was held at a later date, and sanction given to borrow £4,072 and £2,428 for three and eighteen years respectively. This procedure is not quite consistent with the usual practice of the Local Government Board, in that the Department have still to meet interest and loan charges on outstanding debt on discarded plant, for a further term of twelve years, even though same be non-existent.

The past year's results for the fifteen months ending March 25th, 1908, have clearly demonstrated the benefits resulting from the concentration of working and scrapping of out-of-date plant.

The 1905 works costs item of 1·193d. per unit sold has been reduced to 0·818d. This reduction, however, is not altogether attributable to the more economical working of rearranged plant, which has only been in operation six months, but to a combination of the economies effected by the new scheme: an increased power output, the increase of water output, and to the improved conditions of working the water plant resulting from our having full control of the whole water supply. [This was the result of successful negotiations for the surrender of two water-wheels used by the Worcester Royal Porcelain Co.]

It is also necessary to state that the estimated fuel costs were based upon coal at 9s. per ton, which price was increased to 11s. 10d. per ton on October 1st last.

A brief description of the turbine plant was next given in the Paper:—

The water turbine room is of very ample dimensions, having been designed to contain four vertical "Victor" turbines of 54, 54, 48, and 36 in. respectively, and considerable duplicate steam plant. In constructing this building it was necessary to excavate to a depth of 38 to 45 ft. below the floor level. The floor level was fixed some 3 in. above the highest flood, which occurred in 1886.

Little or no repairs have as yet been necessary to the turbine motion work after thirteen years' working. Belt-driven centrifugal governors were originally used for raising or lowering the cylinder gates, but this apparatus has been discarded as unsuitable for our conditions of working. As the available head very seldom exceeds 10 ft., it follows that large volumes of water

Digitized by Google

have to be controlled quickly, otherwise the pressure of the supply quickly attains a dangerous limit if the load suddenly alters. Hand regulation of gates has proved to be the most satisfactory method of control, though the question of motor control is under consideration.

The following general points were also mentioned :—In erecting turbine plant it is essential that ample space be provided for the wheel to discharge into, for if there is not ample space

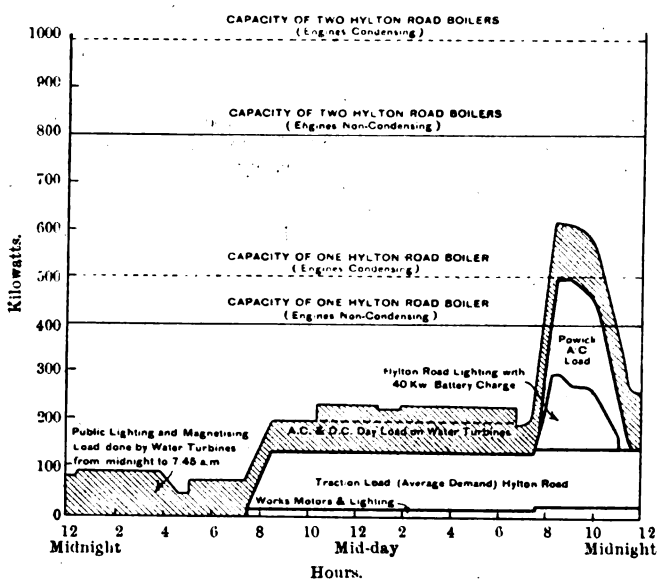

FIG. 1. (SATURDAY, MAY 6TH, 1905).—CHART SHOWING ADDITION OF STEAM-GENERATED OUTPUT FROM POWICK DURING EVENING WHEN WATER SUPPLY IS GOOD, NIGHT AND DAY LOAD TAKEN UP BY WATER TURBINES.

under the wheel for the water to pass away easily and quietly, it will react upon the wheel, and reduce its output to a serious degree. Another important point is the provision of a rack across the head flume to stop foreign matter entering the wheel, which might soon cause an extensive breakage. The area of the head race should be of ample width and depth and free from obstructions, to allow the water to flow quickly and easily to the wheels, and it is most essential that the discharge should pass away in a similar manner, otherwise the efficiency of the plant is sacrificed, and the working head considerably reduced. Unfortunately, the growth of timber along the course of the

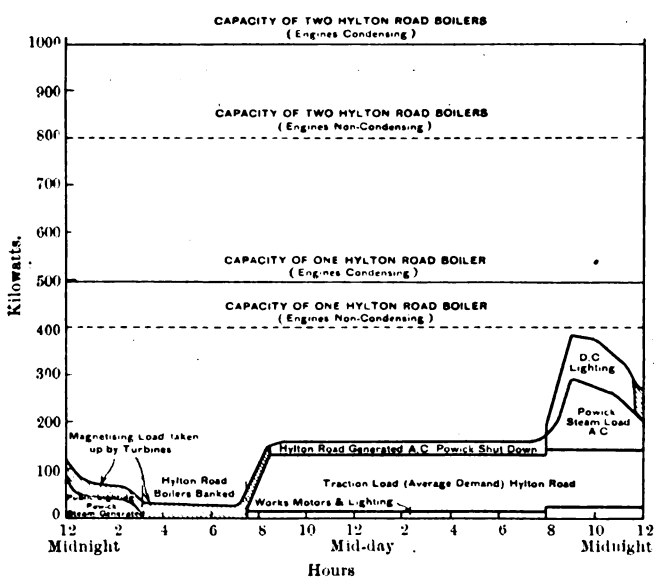

FIG. 2 (WEDNESDAY, JULY 26TH, 1905).—CHART SHOWING TOTAL STEAM LOAD DURING TIME WHEN WATER SUPPLY IS ONLY SUFFICIENT FOR SUPPLYING A PORTION OF NIGHT LOAD AT POWICK.

Teme, and the rapid flow of that river causes many old roots and silt to come down during times of flood. Obstructions are thereby formed which greatly hamper the flow of water. This applies more particularly to the tail race and the 1½ mile stretch of water from the works to the River Severn. This length has become very foul with stranded trees and the silt collecting, so causing shallow fords, with the result that the summer level of the tail water has risen over 2 ft. since the works commenced.

As has already been stated, the conditions of working at Powick were extremely variable from day to day, owing to the varied output of water plant. When the water supply is satisfactory, the running load factor of the water plant is ideal. The night and public lighting loads, together with a 30 h.p. motor at the water works is dealt with by water power from midnight on such occasions as these. After the extinction of public lighting in the morning, a second 30 h.p. motor is taken on, both being run continuously up to dusk. From the time when the public lighting is switched off, water begins to store up, and in the middle of the morning it is possible to start the motor generator for battery charging, so further increasing the value of the water. If these conditions of working could be continued, the works costs would come out at 0·10d. to 0·083d. per unit generated. The good effect of the water in such a case is neutralised to a certain degree, however, by the poor load factor on the steam plant on such a day.

Fig. 1 has been plotted showing the output of the water-power station on such a day, superimposed on to the output at the D.C. station. It demonstrates clearly the more economical condition of working, when the water is good, and the benefits that would have been derived had all steam plant been concentrated at one station.

A similar curve, Fig. 2, is obtained by superimposing the curve representing the conditions at the water-power station on Wednesday, July 26th, on the D.C. load at the new station for that day, and it affords an example of the worst conditions experienced with the turbines, when it is better to store up

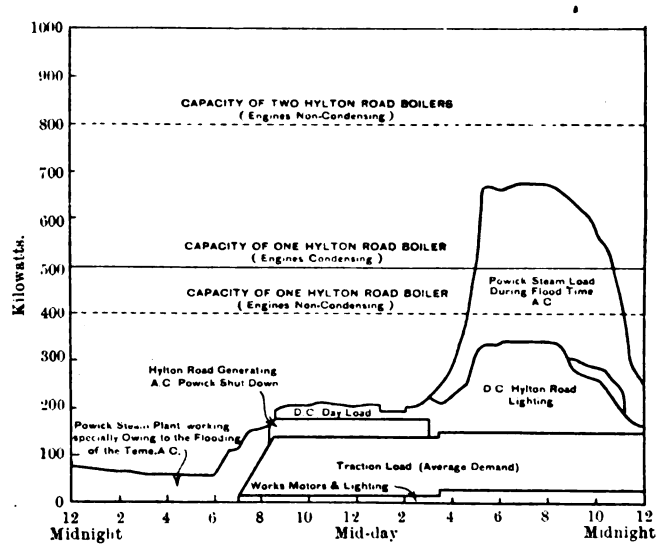

FIG. 3 (SATURDAY, JANUARY 20TH, 1906).—CHART SHOWING IMPROVED WORKING OF BOILERS AT HYLTON ROAD.

water for use on peak and deal with all output from the steam plant.

On January 20th, 1906, all A.C. load had to be dealt with by steam plant at the old station, through the turbines being drowned out by flood, the motor generator at the new works taking up the day load.

Fig. 3 shows the advantage that would have been obtained by amalgamation of the two plants at one station on that day.

The yearly outputs of current generated by steam and water power at the two stations have been plotted out in Fig. 4. From this the fluctuations to which the water-generated output is liable are clearly seen. During the early years of the undertaking, full use could not be made of the water supply, as the demand during certain hours was limited. The water output in 1901 only totalled 337,000 units, prolonged droughts being the cause of the small output. In 1902, the increase was exceptional, there being a steady flow of water throughout the year, after which a period of erratic flow was experienced which greatly affected the returns. The units reached the low-water mark in 1904, when only 293,000 units were generated. The two following years, 1905 and 1906, were also poor, though the output rose slightly, which was not due to an improvement of water flow, but to an increased power output.

The greatly increased output for power and the altered conditions of working since the steam plant has been concentrated at one works, together with a good supply of water during 1907, enabled good use to be made of the water power during the last year, with the result that 500,771 units were generated, which figure, it is hoped, will be exceeded in the future now that there is control of the full flow of water.

With one or two exceptions, the rise and fall of works costs from year to year inversely follows that of the water output. This effect is more clearly shown on the weekly cost and output

Digitized by Google

curve for 1906 (Fig. 5). Fig. 6 gives a comparison between the poorest and best annual water outputs.

A series of floods were experienced during January and February, 1904, which greatly reduced the utility of the water by flooding out the turbines. From April to October, a decline took place, through a continued drought, and it was not until

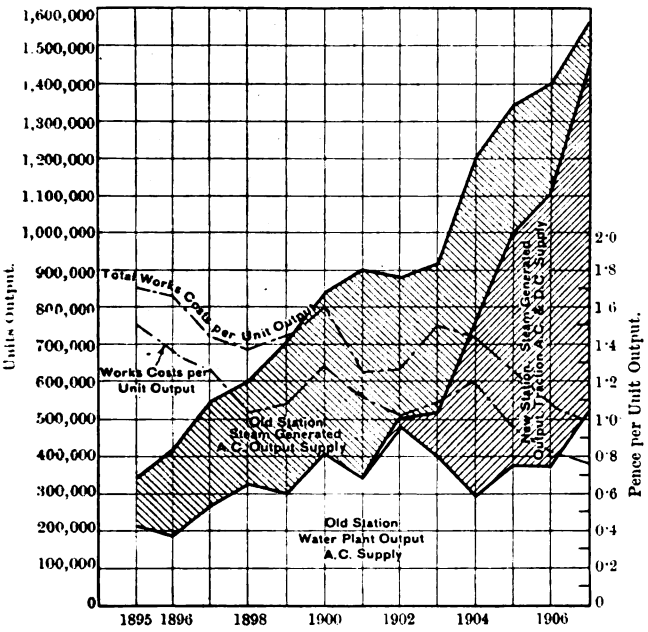

FIG. 4.—CURVES SHOWING RELATION BETWEEN TOTAL WORKS COSTS. WORKS COSTS AND OUTPUTS BY WATER AND STEAM PLANTS.

December of that year that the effect of the autumn rain was felt. The 1907 unit curve shows fluctuations of output through the effect of small floods during the early part of the year. The usual decline commenced during April; the effect of this loss of power was, however, prevented by full control of the water being obtained, as previously explained, so causing the hump, and avoiding the usual fall during the summer. The small

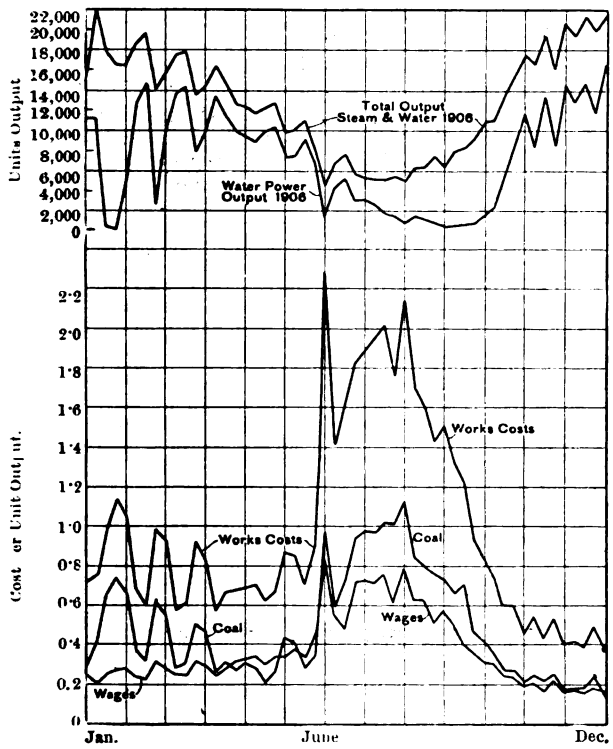

FIG. 5.—CURVES SHOWING RELATION BETWEEN WATER OUTPUT AND WORKS COSTS, &c., IN 1906.

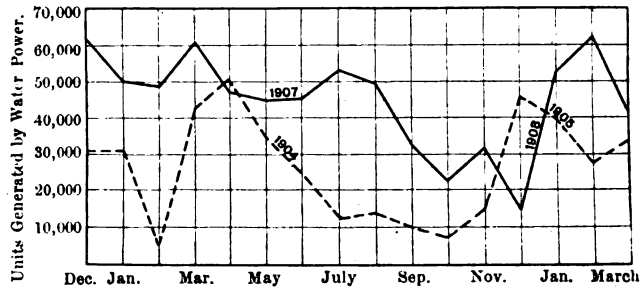
output of October, November, and December was brought about by continued floods, which reduced the annual output by at least 100,000 units.

Due consideration must be given when comparing these curves to the fact that full use has been made of the water power during 1907, through having a sufficient outlet for same, whereas during 1904 only a small amount of power was connected. Undoubtedly, it is necessary to have a market for all current generated by water plant, otherwise full advantage cannot be taken of such power.



Years Output.

FIG. 6.—CURVES SHOWING RELATION BETWEEN THE HIGHEST AND LOWEST ANNUAL WATER OUTPUT.

In conclusion, the author has no hesitation in saying that a water-power plant similar to that at Worcester is of great value, if there be a direct market for such power, without the intervention of wasteful storage entailing heavy capital expenditure. He does not consider any system of storage entailing accumulators of sufficient capacity to take the maximum output is justifiable, as the maximum only endures for short periods. The proper combination is to build up a sufficient mean load throughout the day that such mean shall be greater than the maximum of the water output, surplus demands being taken up by steam sets of suitable size.

DISCUSSION.

Mr. E. E. HOADLEY (Chief Electrical Engineer, Maidstone) said that the Worcester station was one of the very best examples where an undertaking could be turned from, he might say, a bad failure to a very great success. Mr. Shaw had had a very high and, to a large extent, useless capital expenditure, as a very large proportion of it was in bricks and mortar. He had also an old-fashioned system and a very high periodicity, and its being a single-phase high-periodicity alternating-current system had practically debarred him from getting the power load, which was the only hope of salvation. Worcester, with its water power, was a place in which a big power load would be perhaps of more £ s. d. advantage than in any other place in the country. As they all knew, the original station, some two or three miles out of the town, had been intended for and designed as a water-power station, but it had really become a steam-driven station, with a lot of capital expenditure on the water plant which was to a large extent useless with the system which they had in use then. He felt certain that they could now build up a very profitable undertaking by means of the continuous-current plant, and by gradually changing over the single-phase 100-period system to a two-phase 50-period system, as Mr. Shaw was doing. Mr. Shaw had been able to make a very much larger use of the water power, which cost him practically nothing, and, by doing away with steam generation at Powick, he had saved a very great deal of money by the improvement in his boiler load-factor, and by turning out his steam units on economical plant instead of by turning them out with old-fashioned plant. The people responsible for the original design of the station thought the necessity of using the steam plant might occur on two or three occasions during the year when the water-power plant should be shut down either from drought or flood, but from his experience during the time he was at Worcester, these periods were sometimes of longer duration than the actual days when they made profitable use of the water power.

Mr. J. K. BRYDGES (Chief Electrical Engineer, Eastbourne) said that from his experience at Eastbourne there was no question whatever that it was best, when they were getting into difficulties with old plant, to take very severe measures, and go on for something new. When the Eastbourne Corporation acquired its undertaking from a company in January, 1900, they took over the old plant housed in the bottom floor of a building which was originally a brewery, and the upper floors of it consisted of stores, which contained a large quantity of inflammable matter such as hay and straw. The switchboard was very dangerous, and there was no doubt whatever that if there had been a fire the whole place would have been burnt down. The generating plant included belt- and rope-driven sets and two modern direct-coupled engines. There were two Hornsby boilers of the water-tube type, which were not now made, and these were all they had in the way of modern boiler plant; the remainder consisted of semi-portables and a loco boiler. It was decided that it was impossible to extend on that site,

Digitized by Google

and as they had to do something, it was finally decided to go about one and a half miles out of the town and build an entirely new works. They moved the two direct-coupled sets and the two boilers referred to, and at the same time they changed their periodicity from 83 to 50, and did away with as many of the old-fashioned house transformers as possible. When they were changing over, they had to run both stations at the same time. The works costs had also been reduced by about 1½d., and although they were still running for the greater part non-condensing, and suffered from the disadvantage that south coast towns were not very favourably placed with regard to coal supplies, they were doing very well, and he put it down to the fact that they scrapped most of the plant and put in new and modern machinery at very considerable cost. Of course, they were struggling under the very big capital expenditure which they had had to pay to buy up the late electric light company. Mr. Shaw was suffering in exactly the same way, viz., from a very big capital expenditure on old plant which he had had to scrap.

Mr. E. B. VIGNOLES (Chief Electrical Engineer, Grimsby) thought that the author had not quite made out a case for water power in England, and that if he were to start again he would consider very carefully whether he would not dispense with the water turbine station altogether, and concentrate the whole output in one station, generating with larger steam units. The works costs could then be brought down considerably below what they were at present for the two stations; the capital costs would also be lower, and in that way the final result would be more satisfactory. He thought that governing of the turbines by hand, as the author did, would not afford good pressure regulation if there was a variable power load.

The PRESIDENT (Mr. H. Talbot) said that Worcester seemed to be one of those places where there was a river, and people thought that thousands of horse-power were running to waste. People in Nottingham had thought the same, and that thousands of horse-power were running to waste at the Weir, and that he was a fool not to make use of it. He remembered some years ago, when the British Association met in Nottingham, the late Sir Frederick Bramwell opened a discussion on water power at the University College, when he warned the members about water power, and said that he had been caught himself, and gave an instance. He said that some years previously he had been at Bristol, and had casually mentioned the enormous horse-power in the rise and fall of the tide. Some two or three years afterwards the Bristol Corporation wrote to him and asked for his advice for utilising that power. Sir Frederick went into the question very closely, and replied that he had been a fool. Mr. Talbot suggested that Worcester had probably been in a similar position.

Mr. SHAW, in a brief reply, said that although he had had to make the best of what he found, from the knowledge which he had acquired he felt that the water-power station ought to be worked, but he would not have put in so much brickwork and foundations as had been put in. The foundations for the boiler-house were run down to the same level as in the engine-room. The undertaking had been hampered immensely by the large capital expenditure, but as soon as the capital charges were paid off in eleven or twelve years, the water power would be particularly useful.

Friday, July 3rd.

Two Papers were discussed, the first dealing with a suggestion for employing accumulators in a generating station upon a much larger scale than hitherto, and the second on the testing department of an electricity works.

THE USE OF ACCUMULATORS FOR PEAK LOADS.

BY A. M. TAYLOR.

(*Assistant Electrical Engineer, Birmingham.*)

Many causes have conspired to delay the introduction of accumulators into central stations in this country for the purpose of supplying energy for light and power during the time of peak load. The non-fulfilment of the great expectations raised some twenty years ago has had its effect, and numerous failures in actual practice have caused central station engineers to lose confidence in all cells of every make for light and power supply as a substitute for generating plant. With a view to establishing confidence in cells of large capacity for this purpose, the author included in his Paper lists of the large batteries installed at several Continental and American stations.

On the question of efficiency, the author said that, if cells are installed exclusively to take the peak of the load, and are not discharged unnecessarily, the value of the energy wasted in the cells and accessories is only of the order of 1 to 2 per cent. of the value of the revenue introduced by them. He referred to the curves in Fig. 1, the lower one of which he took to represent a typical load curve for a station having a present maximum demand of 5,000 kilowatts. All further extensions are assumed to be carried out with batteries till, in 1913, the maximum demand reaches 10,000 kilowatts. Neglecting changes in the load factor, he assumed that, say 5,000,000 units are sent out in 1908, and 10,000,000 units in 1913. The battery would thus have introduced a revenue of, say, £31,200 per annum (if 1½d. be taken as an all-round price for light and power and losses in transmission are neglected in each case).

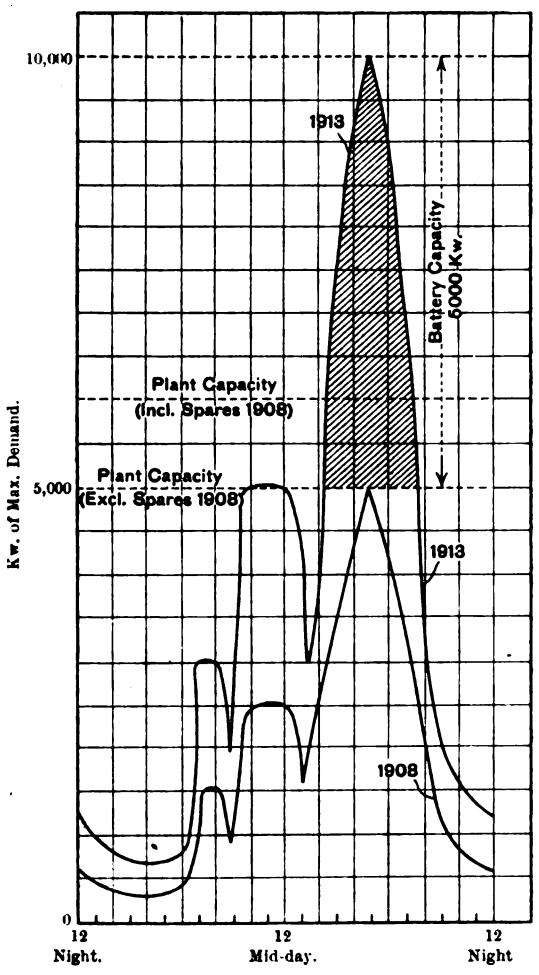

FIG. 1.

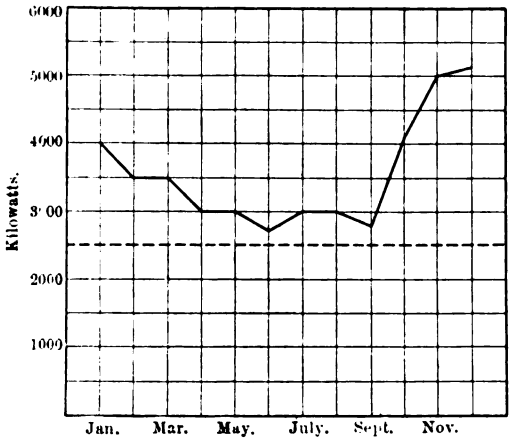

FIG. 2.—MAXIMUM DEMAND AT NEPTUNE BANK FOR EACH MONTH OF 1903. (EIGHTY PER CENT. OF THE UNITS WERE SUPPLIED FROM STATION, WHILE THE MAXIMUM DEMAND WAS UNDER 2,500 KILOWATTS, AS SHOWN BY THE DOTTED LINE.)

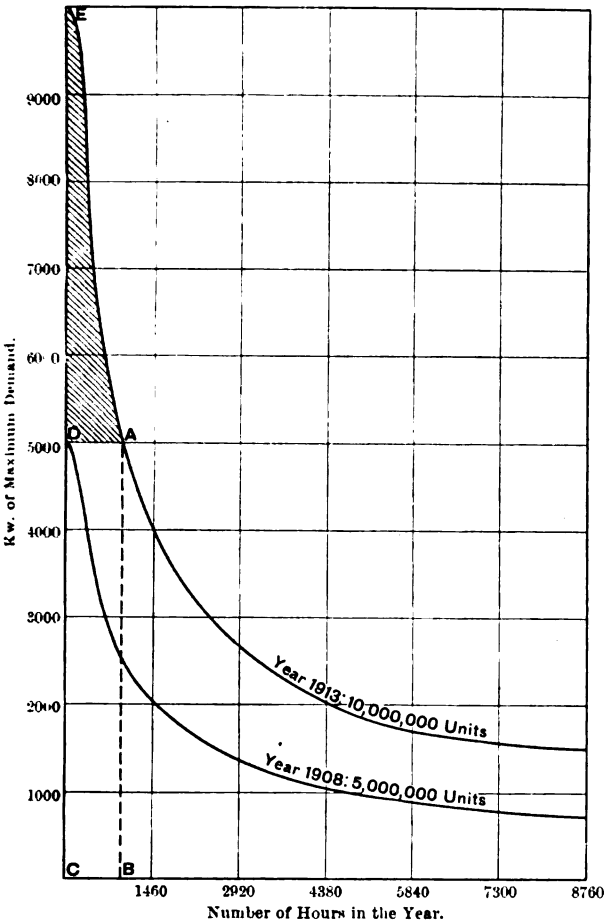
Fig. 2 shows the figures published for the maximum demands at Neptune Bank by Messrs. Merz & McLellan in April, 1904; from this the author has compiled the lower curve in Fig. 3 as a rough approximation to the relative periods of time which the station was working during the year on different loads.

Digitized by Google

The upper curve of Fig. 3 assumes that a battery has been added, and that the output is increased from 5,000,000 to 10,000,000 units per annum, and that the batteries are only called upon to deliver energy when the peak exceeds 5,000 kilowatts. They are, of course, to be charged when the load is small, and the engines and boilers inefficiently loaded. The area *ADE* is to be supplied by the batteries only. To simplify the question, the author has only considered the employment of the battery in the winter, and for discharging at the heaviest peaks.

Some 1,100,000 units are put into the battery; of which some 700,000 are reclaimed as "useful" work; an overall efficiency of 68 per cent. is assumed. The cost of the coal, water, and petty stores consumed to produce these 400,000 units is assumed to be one-fifth penny per unit, or £334, which is slightly over 1 per cent. of the £31,200 mentioned above.

In the comparison next made it was assumed that there is no provision for dealing with fog loads, and that only sufficient



Area (*ADE*) + Area (*ABCD*) = 2,000,000 units : 80 per cent. of the units supplied are to the right of dotted line *AB*.

FIG. 3.—DIAGRAM SHOWING THE USE OF BATTERIES.

spare plant has been allowed to cover the chance of a breakdown of one of the generating units. A series of curves and tables were worked out on this basis, for a typical station for a series of six years, during which the output increased from 20 million to 54 million units per annum, the maximum demand from 12,000 to 29,400 kw., and the load factor from 19 to 21 per cent. In these, the costs of capital charges were calculated in detail, first on the assumption that the original plant capacity of 16,000 kw. of steam plant was gradually increased year by year to 32,000 kw. by adding new steam sets, and then on the assumption that the steam plant was not added to, but that batteries were put in as required to meet the increasing load. The capital cost of the cells and their accessories inclusive of building was put at £15 per kilowatt. Interest charges on the cells were taken at 3 per cent., and depreciation and maintenance charges at 9 per cent.

The author estimated that the savings introduced by the cells, as against steam plant, were £12,000, £24,000, £37,000, £46,000, and £64,000 respectively, in the first five years, these figures representing saving in total costs, including allowance for interest and sinking fund.

Incidentally, the author suggested the employment of accumulator sub-stations on alternating current systems. From inquiries made of accumulator companies, he has found that, where cells of very large individual capacity can be installed, it is possible to obtain a discharge representing 6 kilowatts (on a three-hour basis), for every square yard of floor space, for a single tier of batteries; and where there are two tiers this would be raised to 12 kilowatts, or if three tiers, 18 kilowatts per square yard of ground space. These figures do not include any space for the rotary converters, or the boosters or auxiliary apparatus. He thinks that a separate single-floor building of cheap construction could be erected for the cells for something under 7s. 6d. per kilowatt; or where the cells were arranged on two floors, or even three floors, that the cost of such a building need not exceed say 15s. to £1 per kilowatt. He proposes to use the batteries to deliver alternating current of high pressure into the line at times of peak load, while at the same time delivering direct current of suitable pressure to the 'bus-bars of the sub-station, and believes that this and other combinations would be valuable as a means of relieving the main generating station and feeders at the time of peak load. The efficiency to be obtained on discharge, as between battery terminals and E.H.T. A.C. 'bus-bars, will, in a large sub-station, he maintains, be found to be of the order of 93 per cent., and that between the battery and the sub-station D.C. 'bus-bars of the order of 87 per cent., and even in a small sub-station he is of opinion that these figures would not be materially less than 90 per cent. and 82 per cent. respectively.

We have endeavoured in the above abstract to indicate the author's general conclusions, and his main line of argument, and have also quoted some of his figures. Owing to the peculiarly diffuse method which Mr. Taylor follows in setting forth his assumptions and working out his deductions, and the necessity that he has found of making a large number of alterations in his figures, tables, and curves, since the Paper was first circulated, it has been impossible to do more than this. The same reason accounts for the fact that the speakers in the discussion were only able to deal with the general aspect of the question, as it is practically impossible to follow the author through the entire argument in his Paper.

DISCUSSION.

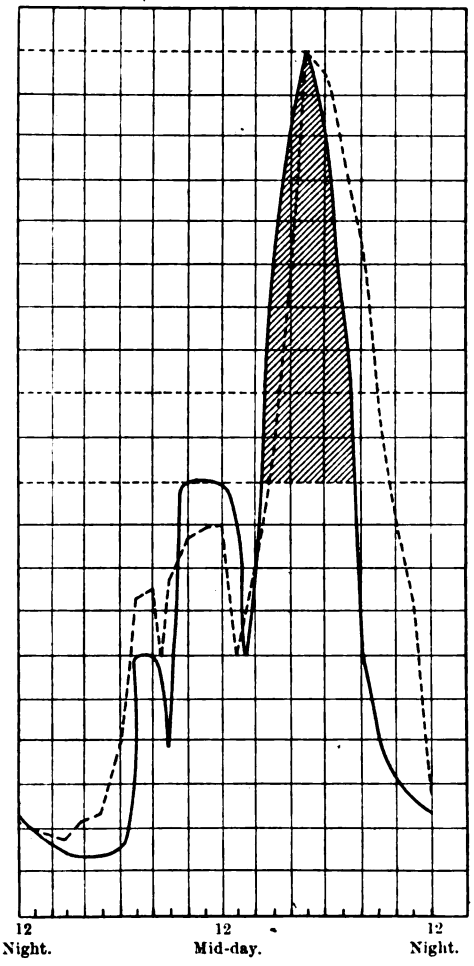
Mr. T. P. WILMSHURST (Chief Electrical Engineer, Derby) said he proposed only to deal with one or two general considerations. He would first like to draw attention to the title of the Paper. It was rather curious that whilst it was headed "Alternating-Current Sub-stations," A.C. sub-stations only took up something like two pages out of fifty of the whole Paper. The principal portion of the Paper was devoted to a consideration of taking the whole load of the peak for the next five years with batteries—rather a bold proposal, and one which he had no doubt would meet with much criticism. He presumed the author only advocated this system with direct-current distribution; he was not quite clear whether that was so. At any rate, if applied to alternating-current stations such as Leeds and Sheffield, the cost of the rotary converters and motor generators would make the scheme unworkable.

Mr. TAYLOR said the scheme would be applicable to any system, whether alternating or direct current.

Mr. WILMSHURST said, therefore, he must contend that its application to Sheffield or Leeds would not be practicable, because the additional cost, both capital cost and working expenses on motor generators, &c., would minimise or wipe out any savings which might accrue from the use of batteries. They must, therefore, fairly confine their attention to systems with direct current. A fundamental difference at once occurred between the conditions of supply, as between a steam plant and a battery plant. In the case of steam plant, the machinery was capable of working at its maximum output continuously for an almost indefinite period. With a battery designed to discharge on, say, the one- or two-hour rate, as soon as that discharge had taken place, the battery was of no further use for several hours, until it was charged up again, and that, to his mind, was one of the most serious defects of the system. With regard to fogs, these did occur, and his experience was that, the larger the town, the more it was liable to fogs, and although Mr. Taylor did give a larger battery for a foggy town, yet it seemed to him that he had rather glossed over this question too airily. Mr. Taylor was obviously dealing with the large towns in his typical case, for the maximum load was 5,000 kw. and the prospective maximum load in five years was 10,000 kw. The author had taken a typical load curve (Fig. 1), and had based his arguments on it, adding in the same diagram a curve for five years hence, which was practically the original curve twice the height, with exactly the same thickness or load factor. But he could not admit that this was a typical load curve. It might be a typical load curve for a purely lighting station, but for a large industrial town he did not think that the peak of the curve was nearly broad enough. He had taken his own case of Derby, which was an industrial town of 130,000 inhabitants, with traction, power, and lighting load, and had superimposed his own load curve on

Digitized by Google

Mr. Taylor's (see diagram below), and his (Mr. Wilmshurst's) load curve was some 50 per cent. fatter at the point at which Mr. Taylor based his arguments. Mr. Taylor would want a 50 per cent larger battery, and a great deal of his saving would disappear. The author also neglected changes in the load factor, but it was not correct to assume that in five years' time their load factors would be no better than they were to-day. Then came the question of ampere-hour efficiency. He believed there were several battery-makers present, and he hoped they would have something to say about it. His impression was that with these heavy discharges of one or two hours, the ampere-hour efficiency of the battery was considerably lower than if the battery were worked in the ordinary way with a discharge of, say, six to nine hours. He would like to hear whether battery-makers would have any objection to constantly discharging the battery at the higher rate. The author had shown in the Paper the enormous batteries at Chicago, but did not say whether they were used regularly for one- or two-hour discharges, or whether they were used, as most of them used batteries, at a slow discharge, the enormous size of the battery being accounted for by the enormous size of the Chicago station. If the batteries were



used for this rapid discharge, he hoped Mr. Taylor would give some figures of working costs at Chicago, and also at some of the German stations, because his impression was that a modern British power station had nothing to learn as to efficiency and economical working from America or Germany. Whilst he could not go as far as Mr. Taylor in his advocacy of using a battery as a substitute, he thought they would all agree that a battery had an enormous use, they had all found it useful as an auxiliary for taking their light loads. In his own case he ran early workmen's cars up to breakfast time entirely from a battery, as well as a good deal of street lighting during the night.

Mr. L. BROEKMAN (Chloride Electrical Storage Co.) said that he was fully aware that prejudice against batteries was still to be found, the reason being mainly that there had been more than one instance in the past in which batteries had enjoyed bad health. But the extreme lassitude in manipulation of the batteries and the use of unsuitable water had a great deal to answer for. In connection with this point, he would like to say that automatic stills adapted for use with either steam or internal combustion engines were a most desirable adjunct in power stations. Frequent inspections were also necessary. He contended that batteries would stand overloads far better than any other class of machinery. Although important improvements in the manufacture of storage batteries had taken place in recent years, there was no striking departures from orthodox practice, and therefore the combination of storage batteries as proposed by the author afforded greater guarantee against antiquation than they had with steam or gas generating plant. That reliable batteries could be made was evident from a case which he knew, in which 3,000 consecutive discharges at the one-hour rate had taken place without the batteries showing any appreciable diminution in capacity. Abundant allowance of lead per cell had been more beneficial, and the practice of some prominent engineers who were in the habit of buying batteries more or less by weight had much to recommend it. The lead weight alone per cell in pounds should be not less than 30 per cent. of the ampere-hour capacity on a slow discharge. [The speaker was next referring generally to some well-known details in battery construction when he was called to order by the President, who pointed out that he was hardly discussing the subject of the Paper, and asked him if he had any information as to whether the use of batteries was increasing in the United States, and whether he could tell the meeting anything about the batteries in Chicago. Mr. Broekman said he had no knowledge of the Chicago batteries.]

Mr. H. RICHARDSON (Chief Electrical Engineer, Dundee) said he yielded to nobody in his admiration of the great amount of work which Mr. Taylor had spent on his Paper, but, he said it with all respect, it was an academic paper. The proposed system would never work out to be a commercial success. All over the country they were just turning the corner; stations were no longer museums; uniformity of plant, and several other valuable policies in the management of stations, and the generation and sale of current, had been initiated, and valuable results were just beginning to appear. And now it was proposed that they should go in for the same old thing that had been the trouble in the past: experiment, experiment, experiment! With regard to load factor, he agreed entirely with Mr. Wilmshurst, and would go even further. He was quite certain that, before this arrangement of Mr. Taylor's was working in a practical way, the conditions would be one of large power stations doing a little lighting, and not lighting stations doing a little power supply. Again, metal filament lamps were in his own town, and others also, already reducing the maximum demand proportionately to the number of consumers they were dealing with, and bringing it down to meet the rise in the power load maximum. Then Mr. Taylor had mentioned in his opening remarks the overloading of a battery for 100 per cent. for a short while, but this was just where the trouble began, and it was where the battery, instead of having a life of five years, would begin to look very "rocky" in the usual time that batteries did begin to look rocky. He had lately been to Germany, where consumers were paying at rates which indicated no particular economy by using the batteries of which Mr. Taylor had given a list.

Mr. J. E. EDGCOME (Chief Electrical Engineer, Kingston-on-Thames) asked how the author proposed to give a supply upon his system, in, say, the City of London. This was a very big supply, mostly lighting, with a comparatively small amount of power at the present time; in fact, the peak load in the winter was from dusk to 5.30. But they had fogs which involved darkness from first thing in the morning until the load came off in the ordinary way at 6.30 or 7. Though that was a load which most station engineers would like to have, what would be the feelings of the engineer who had half his plant in batteries, and had to charge them in order that they might be on full load from 8.30 in the morning until 6.30 at night?

Mr. E. S. NEW (D.P. Battery Co.) said that as makers, his firm would very much like to get 9 per cent. for maintenance, but the utmost they could extort out of the station engineer was 6 per cent., up to the present, so that Mr. Taylor's figure was rather too high. Another point was the question of efficiency which Mr. Wilmshurst had raised. There was no material difference in the efficiency of a batery, either at the one-hour rate or the ten-hour rate; in this he thought other battery makers would bear him out. There might be a slight difference in the watt-hour efficiency, but Mr. Wilmshurst had referred to the ampere-hour efficiency.

Mr. E. S. JACOB (Tudor Accumulator Co.) said that one point in the discussion had been very striking, namely, the tremendous prejudice against accumulators. In the early part of the 'nineties batteries were not what they were to-day, and they proved failures. In the later 'nineties people began to put them in regularly with direct-current supply; they put in a small battery that was useful for the day and night load during the first year, for the day load during the second year, and for nothing at all during the third year. Then they were burdened with the sinking fund on the capital outlay, and said that it was all the fault of the battery. In one of the other discussions it had been urged that when small units had been put down in the past for generating plant, they should be scrapped, but nobody appeared to do this with batteries. Now, however, accumulators had not only been improved, but their cost had gone down tremendously, and what was in those days not commercially possible was now quite feasible. On the question of taking a very high rate of discharge, largely for taking the peak load, he mentioned that this was already done regularly in a tremendous number of stations in Germany, and also in this country. As a matter of fact, the largest battery

Digitized by Google

had been put in a London station, giving an output of from 6,000 to 7,000 kw., and these batteries were useful in time of fog, and offered additional security for taking the peak load under normal conditions.

Mr. J. E. EDGCOME asked Mr. Jacob if he knew what proportion this big battery bore to the entire plant; not 50 per cent., he took it.

Mr. JACOB said it was about 25 per cent.

Mr. H. M. TAYLOR (Chief Electrical Engineer, Middlesbrough) said that the conditions in Middlesbrough had necessitated the Corporation taking a supply from the local power company. The terms of purchase would depend upon the sub-station load factor, and it opened up a very big question indeed in connection with a load consisting of about 2,000,000 units annually, half of which was power load. Throughout the night the sub-station would be absolutely idle, and to get the current from the power company at a reasonable price would depend upon the load factor there.

Mr. F. CHARLES RAPHAEL wished to know to what extent the battery makers who were present backed up the Paper. He would like to know whether perhaps the battery makers had not been treated rather unfairly in being invited to come to the discussion, and whether it was not really a case of "battery makers, battery makers, come and be killed." The Paper said the only salvation with regard to capital expenditure in the future was batteries. The battery makers were asked to come and support this, and then possibly they would be blamed if the arguments were proved to be fallacious. Therefore, if they did not want to answer the questions he was going to ask them, they need not. A statement had been made in the discussion that the ampere-hour efficiency was just as good at the one-hour discharge rate as it was at the ordinary six-hour discharge rate, but from the station engineer's point of view the question of efficiency was simply one of kilowatt-hour input and kilowatt-hour output, and they did not want to go into the academical point of the ampere-hour efficiency and make allowance for the loss owing to the drop in pressure through discharging the battery at a higher rate. If any more battery makers were going to speak, would they say what the watt-hour efficiency at the one-hour discharge rate would be? He would also like to ask a question with regard to the maintenance. A 9 per cent. maintenance contract was assumed in the paper, but they had just heard that some makers would even accept 6 per cent. Would they accept this if the battery was used as Mr. Taylor suggested it should be used? The whole Paper depended on that and practically on nothing else; if the battery was discharged daily at the one-hour rate, and if there was a risk that when a fog came on, it might have to be discharged at a ten-minutes or a quarter-hour rate, would the battery makers be prepared to give the 9 per cent. maintenance? He did not think they would, and he did not see how they possibly could. The one-hour rate of discharge was usually considered as the emergency rate, and he did not think any battery-maker would guarantee this as the regular rate, and four times the discharge rate on emergency.

Mr. S. J. WATSON (Chief Electrical Engineer, Bury) said that one or two points had been mentioned during the discussion which he thought hardly dealt with the subject as put forward by Mr. Taylor. For instance, it had been argued that in foggy districts the battery would probably be totally discharged and meet with entire destruction. He did not see why much should be made of that point. If they considered the case of gasworks, they had exactly the same question to tackle, and there should be no difficulty whatever in proportioning the units so that the battery would be capable of handling the load in conjunction with the steam plant in an equally satisfactory manner. Another point had been raised by Mr. Wilmshurst, and it was one always raised when the question of steam plant *versus* batteries was considered, viz., that they took the capacity of the generating plant and said it was capable of giving its output 24 hours a day, whilst a battery would only give its output for from one to three hours, according to the rating. He did not think that point should be emphasised in this way, because the peak never exceeded one, two, or three hours, and the extra length of time that they could use a generating set was of no use to them. The whole thing, however, really came down to the question of load factor. If they were going eventually to obtain load factors from 25 per cent. to 35 per cent., he did not think the handling of the bulk of the output by means of a battery was likely to be of any use, but he did conceive that in cases of purely lighting districts where the load factor was only from 10 per cent. to 15 per cent., a battery might be exceedingly useful. With regard to the question raised by Mr. Taylor, of Middlesbrough, respecting bulk supply from a power company: as the prices charged for bulk supply were so much per kilowatt, and say about a farthing per unit, where the load factor of the district to be supplied was comparatively small, there was not the slightest doubt that excellent use could be made of the battery. He had been looking into the costs in connection with the few batteries with which he was connected, and found that taking the one-hour rate, the capital cost of the battery, with buildings, worked out at approximately £8 per kilowatt, and came up to £19 or £20 on the seven-hour rate. He quite agreed with the last speaker that the question to be considered was watt-hour efficiency, and not ampere-hour efficiency; but if the battery dealt with the peak only—say 10 or 20 per cent. of the total output—the actual efficiency of it was not a very great consideration.

Mr. P. J. TIDDEMAN (Chief Electrical Engineer, Stoke-on-Trent), on the question of cost, pointed out that although the depreciation of the battery was paid out of revenue, there was also the sinking fund to take into account, and as they could not borrow capital for more than ten years for batteries, there was something like 10 per cent. to go on to that. With regard to fogs, these were so indefinite that they ought not to count on more than 50 per cent. of the discharge capacity for regular use, and they would have to put in a very much larger battery. There was one very good use to which a battery could be put, and that was, it was very useful indeed for burning out faults.

Councillor J. H. MCGAUL (Birkenhead), speaking from the chairman's point of view, said he had looked over the Paper, and really expected very great things from it, but from the discussion and from the criticism that had been heaped upon the Paper, his hopes had been dashed to the ground. At the Birkenhead station they were now full up with steam plant, and had no more room, and his object in coming there that day was that he thought they might be able to put in a sub-station of accumulators that would be a great profit to them.

Mr. C. TURNBULL (Chief Electrical Engineer, Tynemouth) said he was in Italy a little time ago, and had seen some very enormous batteries there, and this, in conjunction with the fact that they were used to an enormous extent in America and also on the Continent, showed that there must be more in them than many supposed. One of the reasons that batteries in the past had given bad results had undoubtedly been the instructions of the accumulator-makers. Battery-makers said they must only have pure water, but it was frequently found that there was no pure water to put into them. He had sent to one of the best-known battery-makers in the kingdom, and asked them to advise him as to a means of getting pure water. After about a month or so, they sent him on a drawing of a most elaborate condensing plant to cost £500. This proved that they had never really gone into the matter at all. He had been told by some battery-makers that he must not use lead stills and must not take steam out of the boilers. If accumulator-makers would go into the matter properly, and get up a pamphlet telling people what to do, it would greatly help them and greatly help others. When electric cabs first came up, he asked a battery-maker how he got on with his battery guarantees, and the reply was that something generally happened which exceeded the guarantee, and then the maintenance was "off." Battery-makers in the past had done this in central stations. In conclusion, Mr. Taylor suggested the use of batteries to level the load in the case of electrified main railways.

Mr. F. A. NEWINGTON (Chief Electrical Engineer, Edinburgh) asked the author in his reply to give the works costs of the stations in America, where these very large batteries were installed; it seemed strange that the really useful figures on which the whole scheme would depend had not been given. Our American friends, as a rule, were not diffident in publishing any records they made, and he hoped that Mr. Taylor would be able to add these figures in his published reply.

Mr. TAYLOR will give his full reply in the Proceedings.

THE TESTING AND STANDARDISING DEPARTMENT.

BY H. A. RATCLIFF

(Testing and Standardising Department, Manchester Corporation Electricity Works).

THE Paper is not intended to constitute a treatise on the arrangement of a testing department, but rather a collection of notes on various features of practical interest with which the author has been brought into contact during the period he has been in charge of the Testing Department of the Manchester Corporation Electricity Works.

The necessity for, and value of, a well-equipped testing department is beginning to be realised, and there is no doubt that the time is not far distant when such a department will be regarded more as a valuable financial asset than as a scientific luxury. Although at present the latter point of view prevails to a great extent, it is a fact that by judicious testing of mains, meters, and distributing apparatus generally, the proportion of units sold to units generated may be considerably increased.

It is probable that there will always be a few small stations where it would not pay to sink the necessary capital in a sufficiently extensive testing equipment, and it should therefore become possible for the necessary work to be undertaken by a larger neighbouring authority possessing the requisite equipment. The author considers this point worthy of consideration by municipal authorities, particularly in such neighbourhoods as Lancashire, Yorkshire, and the Midlands, where the smaller towns practically join on to each other. Another advantage of such a co-operative scheme is that, owing to the extensive and

Digitized by Google

commercial scale on which the work would be executed, the cost would certainly be much below any figure at which it could possibly be undertaken by any college or private laboratory. That the scheme is practicable is shown by the fact that the Manchester Corporation undertake the testing and calibrating of a considerable number of meters for other authorities and companies, &c., and the prices charged are far less than would be the case elsewhere, although leaving a fair margin of profit

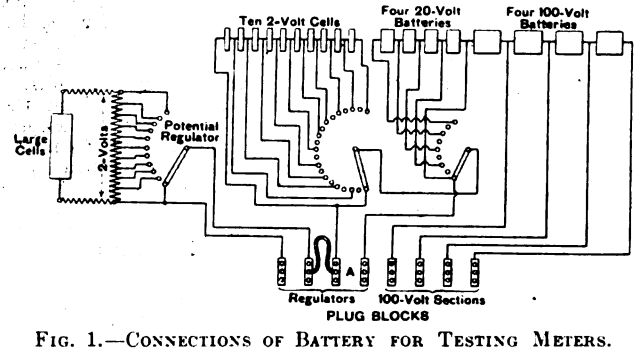


FIG. 1.—CONNECTIONS OF BATTERY FOR TESTING METERS.

on the work. Such a department should also be able to test the candle-power of lamps, &c., and check and calibrate ammeters, voltmeters, and other instruments for consumers and contractors.

Scope of a Testing Department.—Speaking generally, it would appear to be advisable for the testing department to be responsible for, and to carry out, the whole of the electrical and chemical testing that the requirements of the particular station have shown to be necessary. Mechanical and steam tests, &c., would usually be undertaken by the station staff, but even for this work the co-operation of the testing department is desirable for the checking and certifying of any electrical data involved in the calculations. The following list of work undertaken by the department with which the author is connected will, perhaps, serve to indicate more clearly the extent of the duties which may with advantage be allocated to such a department.

For convenience of control, and in order to obtain the maximum degree of efficiency out of the men, the work is divided into two sections:—

Meter and General Testing Section.

Testing, calibrating, and repair of all house service, generating station, and sub-station watt-hour meters.

Testing, calibrating, and repairing of instruments, recorders, and clocks, &c., of every description, from the various generating and sub-stations.

Re-winding and calibration of H. T. instrument transformers.

Conversion of instruments of all descriptions, and the construction of any special instrument or apparatus that may be required.

Photometric tests on various types of electric and gas lamps in the photometer room, and also in the street with portable photometer.

Mains tests of every description, including H. T. tests with portable 30,000-volt set.

Insulation, conductivity, and fault localising tests, &c. Tests at cable-makers' works.

Testing of switches and fuses.

Miscellaneous tests for Tramways Department.

Generally any work of a technical or scientific nature that may rise from time to time.

Motor Section.

Testing of all new and repaired motors, motor starters, and armatures, &c., used in connection with motor-hiring scheme.

Fixing of motors, &c., on consumer's premises and the execution of any repairs which may be necessary whilst on consumer's premises.

Repairs of every description to motors, starters, and accesseries, including the re-winding of armatures, &c.

Construction and repair of resistance frames, circuit breakers, and switches, &c., both for the testing and other departments, and generally the execution of all mechanical work required in connection with the various duties of the Testing Department.

A fairly extensive staff is naturally required to cope with such a large amount of work.

EQUIPMENT.

Supply of Current for Testing.—If the testing and calibrating work is to be conducted with any reasonable degree of accuracy, it is absolutely essential that a steady source of current should be available, quite distinct from any of the public supply circuits. (This, of course, does not apply to motor testing.) For D.C. work, secondary cells fulfil all requirements. A very usual arrangement in test rooms is to have a small number of very large cells, and generally some arrangement of links or plugs for putting them in series or parallel, for obtaining different output currents, &c. The disadvantages of this method are that, owing to the low voltage available, it is difficult to maintain the discharge current constant, unless all the joints and contacts, &c., in the circuit are exceptionally good; very little spare E.M.F. is available for regulating resistances, and it is impossible to test a long row of meters owing to the comparatively large voltage drop. There is also considerable difficulty in measuring the output of the various cells, with the consequent probability of their not all receiving their proper charge, and, moreover, unless a heavy current is used for the purpose, the cells will never be charged at the normal charging rate, and frequently for that reason will not receive the necessary full charge, owing to the increased time required at the lower rate.

These difficulties have to a great extent been overcome by the arrangements adopted at Manchester, and which are as follows:—

The batteries are arranged for two separate classes of work, one consisting of tests which require a small current at voltages up to 500, such as voltmeter calibrations, incandescent lamp tests, and for exciting the shunt circuits of watt-hour meters. The cells used for this work have a maximum discharge rate of about 6 amperes; they are, however, so well constructed that no damage has been done to them by occasional short circuits, &c., involving very much larger outputs. This battery is divided into five sections of 100 volts each, all the sections being joined in series. The first, or "A," section, is further sub-divided as shown in Fig. 1. This arrangement enables the voltage to be raised by one-cell steps from 2 volts to the full 500. By the additional connections to a battery of larger auxiliary cells and a potential regulating resistance, any voltage from 0·2 to 500 volts may be obtained, rising by 0·2-volt steps—*i.e.*, 2,500 different voltages.

For the heavy or main current work, large cells are used; they are connected in groups of ten, each group constituting a unit, and feeding a separate panel on the testing circuits switchboard. Ten-cell units were chosen because experience showed that 20 volts was the lowest E.M.F. that could conveniently be used, when taking into consideration the necessity for absolutely steady currents, adequate regulation, and the possibility of testing a reasonably large number of meters at one time. For larger current than the above, the units are put into parallel at the switchboard. Under no conditions does any unit ever feed more than one circuit at the same time. By the existing arrangements, when once the current taken from the battery has been set to any particular value, it will remain at that value for a sufficient length of time to enable a row of 20 meters to be tested without any readjustment of the current, except in the case of heavy discharges.

The small pressure cells are charged in 100-volt sections off the 200-volt mains, through lamp resistances, about 145 volts being required. The large batteries are charged from a special motor-driven low-voltage generator.

Alternating-Current Supply.—The supply of the necessary alternating current is not quite such a simple matter, as it must of necessity be derived in the first place from rotating machinery. The best source of alternating-current supply is undoubtedly a small motor three-phase generator combination, preferably with a rather slack belt-drive, and the addition of a flywheel on the alternator shaft, should the motor only be comparatively light. If the alternator is large in proportion to the actual output required of it, so much the better, since it can then be used with equally good results for either single-phase or three-phase supply.

Tables and Stands.—The author does not favour the use of elaborately constructed stands and racks in a test room; such stands are never, as a rule, so convenient or accommodating as they are supposed to be, and are more often a nuisance than otherwise. For testing ampere-hour meters of the mercury motor type, and generally all those which are made to stand on brackets, the most simple and convenient arrangement is to have long narrow tables on which two rows of meters can be placed back to back with reasonable clearance between. The tables should be long enough to accommodate about 20 meters in a row. A deep groove or channel should be cut all round the edge of these tables in order to collect spilled mercury, the grooves communicating with small collecting vessels fixed in cupboards or boxes at the end of the tables. Meters of the watt-hour type are generally constructed for fixing on a vertical board, and for testing purposes the most simple and convenient arrangement is to have long wooden partitions, or deal boards, fixed to the wall.

Watt-hour meters when on test require to have all the shunt coils excited from a circuit independent from the one feeding the main coils: otherwise meters at the commencement of a row would have passing through their main coils the shunt currents of the meters beyond them.

LONDON ELECTRIC POWER BILLS

THE FINAL AMENDMENTS IN COMMITTEE.

LONDON AND DISTRICT ELECTRICITY POWER BILL.

THE feature of the final proceedings in connection with the clauses of this Bill was the prompt manner in which the Chairman refused to hear any amendments which were at all irrelevant consequent upon the Committee's decision on the preamble, and the large number of proposed amendments and new clauses which were rejected.

In the first place the London companies intimated their intention of not discussing the clauses on this Bill, and although several attempts were made by various opponents to bring up clauses having the effect of excluding their areas from the operation of the Bill, the Chairman in all cases firmly refused to allow them even to be discussed. Similarly, several amendments were proposed, having the effect of altering the position of municipalities from what it now is under the common law with regard to such matters as breaking up of streets, laying of mains, &c., but they were rejected one after the other.

The first important matter discussed was with regard to Clause 52, "Conditions affecting Supply," which, as we have already announced, the promoters have changed over to practically the ordinary Kitson clause. The only point in dispute was with regard to the 20 per cent. limit for lighting. It had previously been argued before the Committee that in view of the higher efficiency of metal filament lamps, 20 per cent. for lighting on the part of the power-user was too high, and in giving their decision on the preamble, it was clear that the Committee had been influenced by these arguments. The promoters, however, felt themselves unable to offer any suggestions on the matter, but after some discussion the Committee reduced the amount to 15 per cent.

In their decision upon the preamble, the Committee also criticised the proposed sliding-scale clause in the Bill, and the promoters now submitted the following, which the Committee accepted :—"If in any year the revenue obtained by the company from the supply of electrical energy is less by 1 per centum or more than the revenue which the company would have obtained if they had charged for such energy the respective maximum prices set out in the second schedule to this Act, the dividend which the company may pay in respect of that year may be increased above the standard rate to the extent of one-quarter per centum upon the paid-up capital of the company in respect of every one per centum by which the revenue so obtained by the company has been less than the revenue which the company would have obtained by charging such maximum charges for such supply."

On the question of the renewals fund, the promoters accepted a direction by the Committee that this should be obligatory after a 5 per cent. dividend has been paid; the said renewals fund to be at the rate of ½ per cent. of the capital expenditure.

The only outstanding point between the London County Council and the promoters was that the County Council should be specifically mentioned as the purchasing authority pending the creation of some other body by Parliament, but the Committee rejected the proposition, for the reason that they thought they ought not to decide so long beforehand, but should leave it to the decision of Parliament for the time being.

The new cesser of powers clause reads as follows :—

"Unless the company shall within twelve months of the passing of this Act obtain a certificate from the Board of Trade that not less than £600,000 of the share capital of the company by this Act authorised has been subscribed, and unless within two years from the passing of the Act the company shall have substantially commenced their works for the purpose of carrying out their powers under this Act, the Board of Trade, after considering any representations which the London County Council may desire (and are hereby authorised), may order that the powers of the company under this Act shall cease as to the whole or any part of the area of supply, and on any such order being made such power shall cease accordingly."

An attempt was made on behalf of the Brentford Gas Co. to secure special protection in the matter of electrolysis, and to put upon the power company provisions with the object of minimising the possibilities of explosions taking place in street-boxes as the result of leakage into them from gas-pipes, but both were rejected.

For the Westminster City Council, amendments were brought up having the object of safeguarding the rights of purchase which the Council now possesses, and with one or two alterations these were accepted.

With regard to the suggestion put before the Committee by the Coal Smoke Abatement Society that some provision should be made for the prevention of the emission of smoke, the promoters submitted the following, which the Committee accepted :—"Provided nevertheless that nothing in this Act shall exonerate the company from any indictment action or other proceedings for nuisance caused or permitted by the company on any lands used by them for generating electrical energy where such nuisance is caused—(*a*) by non-consumption of smoke; (*b*) by the reasonably preventable evolution of oxides of sulphur; (*c*) by the use of any refuse destructor; or (*d*) by the emission of oil or other matter in conjunction with steam."

LONDON ELECTRIC SUPPLY BILL.

The promoters brought up this Bill redrafted to bring it into conformity with the Committee's decision on the preamble which eliminated all reference to a Joint Committee, &c., leaving it practically a "linking-up" scheme with the additional powers of supply to railways, tramways, docks, canals, &c.

A clause was approved preventing the companies from supplying to any dock undertaking in the Borough of Stepney, or to the Victoria Dock in West Ham, without the consent of the local authority in each case.

The Metropolitan Water Board sought protection with regard to the laying of electric mains near water mains, and asked that when these were within 6 ft. of each other seven days' notice should be given to the Water Board, and that a plan should be submitted, but the Committee rejected the proposition.

On the application of Mr. Seymour Bushe, for the five companies promoting the other Power Bill, the names of these companies were struck out of the schedule of the present Bill, although the promoters strenuously opposed this.

The Committee did not insist upon some clauses proposed by the Commissioners of Works for the protection of Royal palaces and parks, but suggested that the promoters should consult with the Lord Chairman of the Committee in order to arrive at some satisfactory arrangements. The main reason for the Committee's attitude was that the clause in question was retrospective.

LONDON, WESTMINSTER, AND KENSINGTON ELECTRIC SUPPLY COMPANY'S BILL.

There were no contentious clauses upon this Bill; the vital clauses have been brought into line with those of the previous Bill.

The three Bills were then ordered to be reported to the House of Lords for third reading.

The Helion Lamp.—Some further particulars of the Helion incandescent lamp, which is now described as being about ready for commercial use, are given in the *Electrical World* (New York). The inventors, Prof. H. C. Parker and W. C. Clark, have developed a filament which they say is in its final form, and that only mechanical details have now to be completed before the lamp is ready for the market. The filament, as completed, possesses certain very interesting features. It looks like a section of Russia iron, and can be handled almost as carelessly as a piece of wire, although it is somewhat more brittle. The filament is short, coarse, and strong, and is made by flashing a carbon core and producing a deposit of Helion composition on it. The finished filament has from three to five times the diameter of the carbon core, and possesses a very high resistance. Helion has a specific resistance 50 times that of carbon. A remarkable feature of the filament is that it can be heated to incandescence in the open air, and resists attack for quite a long period of time. Another quality is that, being short, it is necessarily immune from the detrimental effects of vibration. Work on the filaments has reached such a point that they are standardised for 110- and 220-volt circuits. It is proposed to make the lamps in standard ratings of 20 and 40 c.p., and for regular voltages. The filament for the 220-volt lamp is 3 in. long, and that for the 110-volt lamp of half the candle-power rating is, of course, only half that length. When heated in the open air the filament shows the pure white light which was characteristic of the lamp when first exhibited. The filament when burning in air is, of course, not so efficient as when enclosed in a globe, and especially in a vacuum; but even in air it gives a brilliant white light. A peculiarity of the filament is that as soon as it is heated, the surface oxidises, and a protective skin is said to be formed which guards it from further attack. The life of the filament burning in air has not been determined, since obviously it is not intended to be used in this way, but enclosed in an ordinary incandescent lamp bulb. An interesting point, especially when viewed in connection with the filaments of other recently developed lamps, is that the cost of the Helion lamp is stated to be little more than that of the ordinary carbon lamp. Thus, while the lamp is claimed to have a higher efficiency than that of other lamps recently placed on the market, its cost is very much less. It is also claimed that a high vacuum is not necessary, so that the slight increase in cost due to the filament itself is partially offset by the saving due to a lower vacuum.

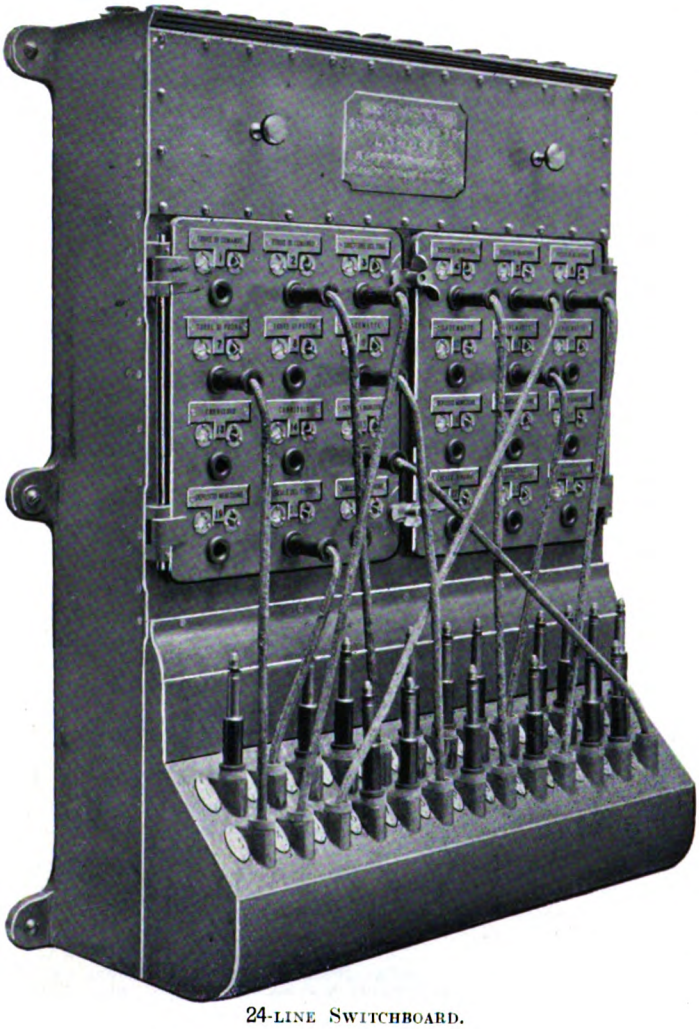
"LOUD-SPEAKING" TELEPHONES

"LOUD-SPEAKING" telephones have become almost as much a necessity in electricity generating stations as on shipboard, especially in engine-rooms in which a certain type of turbo-generator is employed, and they are also now largely used in other works where the ordinary telephone is not suitable. Although in such cases it is rare that a watertight construction is actually necessary, yet the strong mechanical protection of the loud-speaking naval instrument is an advantage, and many people prefer to adopt the standard type that does such good service as a naval telephone. Messrs. Alfred Graham & Co.'s new catalogue, a copy of which has been sent us, contains descriptions and well-executed illustrations of a variety of patterns of this instrument; and it is interesting to note how important details are thought out in the design. Thus in a telephone on a floor pillar, designed primarily for such positions as the navigating bridge of a vessel, but also particularly applicable to the switchboard gallery of an electricity works, the position of the fixed transmitter microphone and arrangement of the rotatable receiver arms is such that the speaker can



24-LINE SWITCHBOARD.

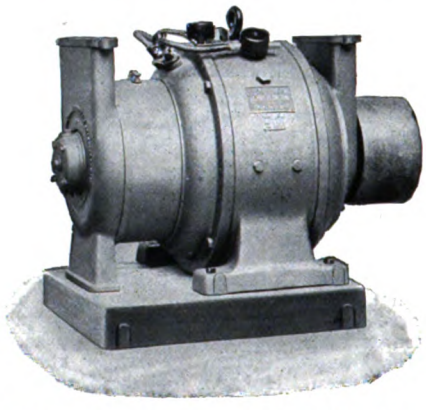
watch any object while he is speaking; and in all the newer instruments a device is fitted by which the carbon granules of the microphone are automatically agitated before the instrument is used. It is stated that speech from these instruments can be heard at a distance of 20 ft. or 30 ft. from the receiver. The catalogue also contains descriptions and illustrations of small exchange switchboards, designed on similar lines to the actual instruments. One of the pictures, which we reproduce, shows a 24-line switchboard, with lamps as calling and clearing signals. The board is a "single-cord" board, so that every telephone can be in use simultaneously, and the number of conversations going on at one time is not limited to the number of pairs of cords as on a double-cord board.

Messrs. Graham & Co. have also recently perfected a system to dispense with primary batteries, and they supply small motor-generator sets, specially enclosed for ship use, which can be employed to take the current from the lighting supply. A power switchboard has been designed for use with one of these sets, and arranged so that the ordinary ship's low-tension supply is used as a stand-by, and comes into use automatically when supply from the motor-generator is not available.

TOTALLY-ENCLOSED MOTORS WITH FORCED VENTILATION

IT frequently happens that electric motors are required to work in dusty or damp places, or in factories where the production of acid-bearing steam or gases is unavoidable. The motors may be rendered fit to operate under these unfavourable conditions by protecting them to a greater or less degree, and they then fall under the heading of partially or totally enclosed machines. As a natural result of this protection a motor for any required output must be considerably larger and correspondingly more costly than an open-type machine. To overcome this objection to the employment of electric motors in places where such conditions prevail, the Felten & Guilleaume-Lahmeyer Company has developed a series of totally-enclosed motors with forced ventilation, which may be rated as equivalent to open-type machines. The motor frame is completely enclosed, with the exception of two openings, one at the pulley end and the other at the commutator or slip-ring end. The former serves for the ingress and the latter for the egress of the air, which is impelled through the machne by a fan mounted on the armature shaft. Each of these openings is in connection with a conduit, in order that the circulating air shall not communicate with the atmosphere of the room in which the motor is at work, but be drawn from a pure source outside the building.

It is, of course, an essential condition for the employment of these motors that a supply of clean and cool air is available without the provision of an excessive length of conduit. The air supply and exhaust connections to the motor may be made either from above or below, the junction pieces cast or screwed to the end brackets being arranged accordingly. In order to give the machines sufficient stability they are mounted on base-plates, in which there are openings connecting the air conduits



ENCLOSED MOTOR WITH FORCED VENTILATION.

with the motor housing, assuming that the air supply is taken from below. When the air supply is derived from above, the bracket at the slip-ring or commutator end of the motor is supported by a foot resting on an extension of the base-plate, as shown in the figure.

Motors with forced ventilation may be employed also without special conduits leading to the open air, in cases where the object of protecting them is to prevent access to their working parts by unauthorised persons, or to render them proof against dripping water in places not otherwise excessively damp. The air openings in the motor housing are then usually directed upwards, and capped by a small hood. Machines built in this way have an advantage over the usual type of ventilated protected or drip-proof motors, inasmuch as their ventilation is considerably superior, and their output for a given size correspondingly higher.

CORRESPONDENCE

ASSISTANT ENGINEERS AND THE I.M.E.A.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—I quite agree with the first part of your Editorial Note dealing with the position of the Assistant Electrical Engineer in the Incorporated Municipal Electrical Association. An assistant, if married and without private means, cannot afford, with the average salary paid, to belong to several institutions or associations, especially the one referred to; and I am afraid that the results of the schemes mentioned will be disappointing until the assistants are treated in the same manner as their chiefs, who in the majority of cases have their subscription and out-of-pocket expenses, incurred in attending the Association's meetings, refunded by their Corporations.

Yours faithfully,

July 2nd, 1908. CHIEF ASSISTANT.

REPORTS ON DEPRECIATION AT COVENTRY

LENGTHY reports with respect to depreciation and obsolescence of plant have been prepared by the Engineer (Mr. J. A. Jeckell) and the city professional auditor (Mr. E. T. Peirson). The conditions under which the loans were obtained, and the sinking fund for their repayment created, are recapitulated, and the purposes for which a reserve fund may be applied are defined. The report continues :—

"Apparently this reserve fund may be used for the following purposes :—(1) To supplement the revenue in a lean year when possibly the revenue did not equal the expenditure. (2) To replace plant which has done its duty and been worn out in the ordinary course at a time prior to the date at which the equated loan, in which it was included, would be extinguished. (3) To replace plant which has proved unsatisfactory and which has had to be dispensed with on that account. (4) To replace plant which has become obsolete or which it is desirable to supersede from any other cause.

"Unfortunately, the Local Government Board have as yet not stated clearly what course they propose to adopt with regard to allowing re-borrowing powers to replace plant which has been worn out in the natural course, the money for which was sanctioned in an equated loan, and therefore it may become necessary to replace a considerable portion of this plant out of revenue before the equated loan has been extinguished. In order, therefore, to meet this contingency, it is extremely desirable that the reserve fund should be built up as rapidly as possible. Many of the loans on this undertaking will be extinguished in twenty years. For the first ten years £1,000 per annum will be required to replace plant which will be worn out in the natural course in that time. During the succeeding ten years £3,000 per annum will be required if the Local Government Board do not grant re-borrowing powers to replace plant worn out in the natural course before the equated loan in which it is included has been extinguished, that is to say, £40,000 in the next twenty years. If this amount is set aside as reserve fund, then the undertaking will be in an absolutely sound financial condition, and I venture to think it will be well if this fact is borne in mind in building up the reserve fund."

Lists of accounts which should be charged to reserve instead of capital have been made, and schedules of all the plant which has been superseded. It is pointed out that many of these items were perhaps rightly charged to the capital account then, though at the present time there is no available asset to represent them; it therefore is desirable that they should be deleted from the capital account of the balance-sheet.

These accounts amount to £10,411, to be transferred from capital to revenue, exclusive of plant superseded. Elaborate schedules accompany the report, showing the totals for each year, the details of the accounts superseded, the details of the plant superseded, the details of the existing plant with the estimated life, the agreement of these amounts with the balance-sheet, the depreciation to date, and depreciation to be found in future years.

The totals of these are as follows :—

	£ s. d.	£ s. d.
Amount of accounts to be transferred from capital to revenue		10,411 0 9
Plant superseded		16,579 17 4
		26.990 18 1
Deduct :—		
Amount at present in sinking fund applicable to these items ...	7,835 0 8	
Estimated present worth of superseded plant	100 0 0	
Sales of plant	1,789 12 11	
Arc lamps already renewed out of revenue	206 0 0	
Amount found for year ending 1906	2,886 9 9	
Amount found for year ending 1907	2,451 13 10	
		15.268 17 2
Leaving to be found for obsolete or superseded plant		11,722 0 11

The lives taken for the plant are based very much on Sir William Preece's figures, which he estimated when he was called in to value the plant for the Bristol Corporation.

The following remarks are made on the subject of obsolescence :—'With regard to obsolescence, as it is called, viz., the plant becoming obsolete because new and better plant is invented, considering the extremely efficient plant we have now here, no account need be taken of this. It is quite true that already some of the plant has become obsolete and has been superseded, but this was because the plant was obsolete at the time it was installed, and there appears to be no likelihood of any vast improvement being made in the generating plant as we now have it, except by some invention which would to a great extent revolutionise the whole of the machinery throughout the world."

The auditor's report agrees generally with Mr. Jeckell's opinions, but he writes as follows upon the question of dealing with assets superseded :—"It was decided by Lord Kyllachy in the Outer House of the Edinburgh Court of Session in 1898, that when a tramway company alters its system from horse traction to cable traction, nothing need be written off capital account before paying dividends out of current profits, as he assumed that the system of conversion would not have been embarked upon were it not honestly considered that the undertaking would, when completed, represent reasonable value for the gross capital expenditure. The same argument might well apply to the alterations effected in your undertaking. In this connection I consider the 'reasonable value' is not actual realisable value, but a capitalised value based upon earning capacity. On the other hand, the Professional Auditors recently appointed by the London County Council to report upon the accounts of their various undertakings issued a report dated March 14th, 1908, upon the tramways undertaking, and therein they stated it as their opinion that the cost of the superseded horse traction must be written off before there can be any profits available for the relief of the rates. I prefer, however, to follow the decision of Lord Kyallchy, and I consider that, seeing the Local Government Board sanctioned a loan for the expenditure in connection with the new plant in connection with the alterations considered necessary, the provision made for writing off the £25,201 5s. 2d. original expenditure for superseded plant, &c., as shown by the Manager's Schedule No. 1, by way of the original sinking fund, is adequate."

Figures are then gone into relating to the amount of the sinking fund, and the conclusion is come to that the sinking fund is adequate to meet requirements in respect of wasting assets.

The report continues :—"The only points, therefore, which remain to be considered are :—(*a*) The provision for renewals required before the expiry of the loan periods. Your Manager, according to his report, estimates that there will be required the sum of £1,000 per annum for the next ten years, and possibly a further sum of £3,000 per annum for the succeeding ten years. (*b*) The risk of obsolescence or serious breakdown. Your Manager states in his report there is little likelihood of this contingency coming to pass, but I consider the Committee would be wise to make moderate provision for the same. I think it would be well to set aside a fixed annual sum to provide for these items, and in all the circumstances I venture to suggest that a fair and reasonable provision would be a sum of £2,500 per annum for the next six years, making £15,000 in all, when the matter could be reconsidered in the light of further experience which will then have been gained."

CATALOGUES AND PAMPHLETS RECEIVED

ACCUMULATORS.—A leaflet from the Chloride Electrical Storage Co., Ltd., of Clifton Junction, Manchester, describes a line of small 14-cell batteries, with capacities ranging from 20 to 160 ampere-hours, for working in small house installations in conjunction with metal filament lamps. The larger sizes are fitted with the latest type of box negative, which is made in two halves, the active material being inserted between.

CONTINUOUS CURRENT MOTORS.—We have received an advance copy of a list of continuous-current motors and starters of the "Fortiter" type, from the Union Electric Co. The list gives for the range and horse-powers that it covers a very large number of alternative speeds for the different horse-powers. Care has been taken in the arrangement of the list, so that all points of technical detail shall be perfectly clear, and dimension drawings are given so that there should not be any delay in the preparation of foundations for the machines which are stocked, completely finished, and tested, in all current sizes. Particulars of air-cooled as well as oil-cooled motor starters with no voltage and overload release devices are also given.

ELECTRIC FANS.—The latest catalogue issued by the Sun Electrical Co. deals with electric fans, and contains particulars of a number of types, including table and desk fans, ventilating ring fans, ceiling fans, and large centrifugal ventilating fans. One of the special types is an electric punkah fan with rocking deflector blades, arranged with the motor completely hidden in an ornamental *repoussé* brass bowl.

IRON AND STEEL TUBES.—A catalogue is to hand from John Spencer, Ltd., of Wednesbury, giving particulars of a great variety of iron and steel tubes for various purposes, including boiler tubes, steam and water pipes, tramway poles, &c., together with a long series of valves, joints, and fittings. A revolving pocket perpetual metal calender accompanies this useful catalogue.

MOTOR-CAR ACCESSORIES AND SPARE PARTS.—A very complete catalogue of motor accessories and tools, which include also spare parts for a few makes of cars, is to hand from Messrs. G. T. Riches & Co., of 19 Store Street, Tottenham Court Road. We notice particularly lists of spare parts for various makes of magnetos which should be very useful.

SHOW CARD.—Messrs. Siemens Brothers' Dynamo Works, Ltd., are issuing an attractive show card to dealers handling their tantalum lamps.

TRAVEL.—We are favoured with a copy of an artistically illustrated booklet, entitled "East Coast Holidays," from the Great Eastern Railway Co.

THE MANCHESTER ELECTRICAL EXHIBITION

THE arrangements for the electrical exhibition, to be held at Platt Fields, Rusholme, Manchester, are now very well advanced, and considerable progress has been made with the special building which is being erected for the purpose. At the invitation of the management, a large party, including a number of representatives of the technical and daily Press, made an inspection of the building on Tuesday, and were entertained at lunch in the portion which is now completed. The site of the exhibition has already been indicated in ELECTRICAL ENGINEERING, Vol. III., p. 551, when a map of Manchester, showing its position, was published. The skeleton of the building is of wood, as this form of construction was considered more suitable than steel for temporary purposes. The framework is all in place, but of course a good deal of the roofing and walls remains to be completed; nevertheless, sufficient advance has been made to render it possible to obtain an excellent idea of its scope. The exhibition will be held in a single building 500 ft. long by 185 ft. wide, and the stand space will amount to 65,000 sq. ft., or more than the total available even at Olympia. The building is by far the largest temporary structure that has been erected in the North of England. The foundations for the sub-station in the centre of the building, through which the supply from the high-tension corporation mains will be taken, are already in place, and this promises in itself to be an exhibit of some interest.

Councillor W. KAY (Deputy Chairman, Manchester Corporation Electricity Committee) occupied the chair at the luncheon, and was supported by Councillor W. Barrett (Chairman of the Salford Electricity Committee). Amongst the engineers of corporations who are supporting the scheme, we noticed Mr. S. L. Pearce (Chief Electrical Engineer, Manchester Corporation, and President of the Incorporated Municipal Electrical Association), Mr. H. Talbot (City Electrical Engineer, Nottingham, Past President of the I.M.E.A.), Mr. A. A. Day (Borough Electrical Engineer, Bolton), and Mr. S. J. Watson (Borough Electrical Engineer, Bury). The National Electrical Manufacturers' Association was represented by Mr. F. H. Nalder (Messrs. Nalder Brothers & Thompson) and Mr. H. H. Berry (Messrs. Berry, Skinner & Co.), and among the members of the General Committee representing the exhibitors there were present Mr. H. Bevis (General Electric Co.) and Mr. D. N. Dulop (British Westinghouse Co.), and the management was represented by Mr. C. S. Northcote (general manager) and Mr. W. Davenport (secretary).

The toast of the Press was proposed first of all by the CHAIRMAN, who spoke of the reasons for holding the exhibition in Manchester, which city he described as the centre of commercial growth of the industrial applications of electricity to be exemplified in the exhibition. He looked forward to great benefits accruing from the display, and instanced the excellent results which had been produced by a gas exhibition on similar lines. The exhibition was in no way run for private gain, but the object was to forward the interest of both municipal and private branches of electrical business and industry.

Mr. H. TALBOT also spoke from the point of view of the other municipalities supporting the venture, and emphasised the suitability of Manchester for its venue as a more important centre than the other surrounding towns.

The official support of the Incorporated Municipal Electrical Association was spoken of by Mr. S. L. PEARCE, who stated that already some 30 or 40 municipalities, including Manchester, Salford, Nottingham, Derby, Bolton, and Bury, were actively supporting the scheme, and he hoped that several others would come in.

Mr. H. H. BEVIS made a speech expressing his views as an exhibitor. He thought that electrical exhibitions, like doctors, should be called into requisition as seldom as possible. One large representative exhibition, such as they hoped this would be, held at intervals of about three years, was much more productive of good than a multitude of smaller exhibitions.

Mr. W. DAVENPORT then rose to give some particulars of the building and the scope of the exhibition, which, he said, would represent the application of electricity to a number of industries. The exhibits would include special displays of domestic appliances, electric furnaces, textile, wood-working, and other electrically-driven machinery, and lectures and demonstrations would be given. The attractions to the public would be well attended to. Already the band of the Coldstream Guards had been engaged, and an elaborate scheme of illuminations had been planned. They looked forward to even better results in the way of being able to contribute to the electrical charities than were obtained after the Olympia exhibition, and hinted at the prospect of a substantial bonus being returned to exhibitors. Representatives of the Press replied, and after the Chairman's health had been drunk, the party dispersed.

LOCAL NOTES

AMBLE: *Electric Lighting.*—A resolution has been passed by the Council that the Board of Trade be asked to revoke the Provisional Order which the Northern Counties Electric Supply Co. has for this district, owing to their not having put it into force. The Council has other proposals before it with regard to electric lighting.

BARNES: *Electric Lighting Accounts.*—The accounts of the Corporation electric light undertaking for the year ended March 31st, 1908, show a total capital expenditure to date of £60,647, of which £7,114 were expended during the year under notice. There is a balance of unexpended capital of £3,350. The revenue amounted to £10,678, and the expenditure to £4,376, leaving £6,302 to be carried forward to net revenue account. After deducting interest and sinking fund, &c., there is a balance of £4,271, which is carried forward. The number of units sold was 868,942, of which 188,444 were for public lamps and the remainder sold to private consumers. The total maximum supply demanded was 451 kw.

BECKENHAM.—The Urban District Council has decided that a bonus on the year's working of the electricity undertaking be given to stokers equivalent to £10 for each 0·1d. reduction in the coal costs.—The consulting engineers, reporting to the Council regarding contracts for new machinery, &c., stated that the battery and booster in hand are well advanced. The Underfeed Stoker Company are to instal a new trial stoker.

BELFAST: *I.M.E.A.*—At the weekly meeting of the Tramways and Electrical Committee, held on the 6th inst., Sir Robert Anderson, Lord Mayor, presiding, Mr. T. W. Bloxam, electrical engineer, reported that he had attended at the Conference of the Municipal Electrical Association in Nottingham, and obtained much valuable information which would be for the benefit of the undertaking.

BOURNEMOUTH: *The Recent Tramway Accident.*—With the object of preventing further accidents on the Poole Hill route, new regulations have been put in force. There is a new stopping place between Poole Hill and the first curve, and drivers are to test all brakes on leaving the brow of the hill and at each terminus.

BURNLEY: *Tramways.*—At the meeting of the Burnley Town Council last Thursday, in referring to a decision to purchase 50 watt meters for the tramcars, it was asked if they could be relied upon at £5 each. Councillor Aspinall said that at Bradford they had brought about a saving of 10 per cent. on electricity. The efficacy of these meters was called into question, and the matter was eventually referred back for further consideration.

A complaint was laid before the Council regarding the bad ventilation of the electric tramcars, and a suggestion was made that the committee should have at each end of the cars a wire gauge with a movable cover, which the driver or conductor could operate at will. Attention was promised to the matter.

Electricity Accounts.—The electrical engineer has issued his annual report, which shows the growth of the undertaking during the last year to be as follows:—Units for lighting, 638,903, an increase of 79,688, or 14·25 per cent.; units for motors, 192,957, increase 61,530, or 46·81 per cent.; scar top-mill motors (temporary), 326,087, increase 295,078; and units for traction, 2,277,032, increase 44,075, or 1·97 per cent. These give totals of 3,434,979, increase 480,371, or 16·26 per cent. The increase in units for lighting purposes is 14·25 per cent. against 13·32 the previous year for motor purposes, 46·81 against 84·08, and for traction purposes 1·97 against 4·87. The total capital expenditure has been £94,761 7s., an increase of £1,921 19s. 6d., accounted for chiefly by extending mains and consumers' services (£1,293 7s. 5d.). The amount borrowed on capital account has been £95,886, and the total paid off by the sinking fund £22,914 1s. 6d. During the year the net income amounted to £22,389 15s. 8d., against £21,280 3s. 3d., an increase of £1,109 12s. 5d. There had been several reductions in charges. The net profit is £6,254 15s. 6d., against £5,384 7s. 1d. last year, an increase of £870 8s. 5d. The profit has been disposed of as follows:—£3,000 for relief of rates and £3,254 15s. 6d. to depreciation fund. The generating plant remained the same as last year, with a capacity of 1,990 kilowatts or approximately 3,000 h.p. The electrical engineer is of opinion that the question of crane capacity should receive consideration, as some

Digitized by Google

parts of special new plant will exceed 10 tons in weight, whilst the existing cranes are only of 6 tons capacity. The cooling-tower should be extended and made at least half as big again to deal with 66,000 gallons of water per hour, and there should be more ground for storage purposes. That electricity is making headway he concluded for heating and other domestic purposes is now a foregone conclusion. The metallic filament lamp seems to have been almost universally adopted by the consumers, but owing to the increased candle-power, and the fact of having to burn two or more in series, it is questionable whether the higher efficiency lamps have made any material difference compared with the ordinary carbon filament lamps, either in the revenue account or the station's load. At the same time, the consumer has received a much more satisfactory light, and the ultimate result is bound to be beneficial to supply stations.

CARDIFF: *Electric Lighting and Tramways.*—The Electric Lighting and Tramways Departments are the subject of much discussion at the present moment, and at the next meeting of the Corporation one of the councillors will move that an expert be engaged to report upon the tramway track, while another will move that the application of the employees for a conciliation board should be granted.

CROYDON: *Tramways.*—The net surplus on the tramways which were acquired by the Corporation from the company in June, 1906, has been £1,627, as compared with £9,053 for the preceding ten months. There has been a loss of £2.150 on the extension to Thornton Heath, and the Corporation decided last week to discontinue running this part of the line

DUNDEE: *Trackless Trolley System.*—The deputation which was sent to the Continent to inspect examples of the trackless trolley system, has now returned. Their report has not yet been completed, but it is understood that they have a high opinion of the trackless trolley system, and will urge its adoption on the outskirts of Dundee.

EASTBOURNE: *The Generating Station.*—The Electrical Engineer is to report as to the advisability of duplicating the motor driving plant, together with an estimate of the cost. This is in consequence of a breakdown at the electricity station. Recently, owing to the burning out of a motor driving the pump which circulates the cooling water through the condenser of the turbine, the vacuum was lost, and it was necessary to run the plant non-condensing for part of an evening. The Electrical Engineer has reported that the existing water heater and softener, which is used for softening the town water required in excess of that obtained from a tube well, is not giving satisfactory results, and he has suggested that a modern cold process water softener be installed. The Electric and Street Lighting Committee of the Town Council has resolved that the matter be deferred to enable the Electrical Engineer to report further thereon.

EGHAM: *Electric Supply.*—The Egham Electric Lighting Syndicate have given notice that they are about to apply for a Provisional Order for the supply of electricity in this district.

EVANTON: *Bazaar.*—A somewhat unusual course of holding a hazaar in August to defray the costs of the installation of electric light in the village is proposed.

FLEETWOOD: *Rating of Tramroad.*—A case in which the Fleetwood Council sued the Blackpool & Fleetwood Tramroads Co., for payment of rates amounting to £525, has been settled in accordance with a recent decision of the Court of Appeal that the defendants were only liable for quarter rating, and an order for payment accordingly was made.

GUILDFORD: *Staff Outing.*—The staff of the Guildford Electricity Supply Co. held their annual outing last week at Bournemouth.

HANWELL: *Technical Advice.*—The District Council, at its last meeting, agreed that an account of £105 for the professional services of Mr. Russell, consulting electrical engineer, to March 10th be paid, but endorsed the opinion of the Finance Committee that no further expense for technical advice should be incurred without the authority of the Council.

HASLEMERE: *Electric Lighting.*—The Hindhead and District Electric Supply Co. have given notice of their intention to apply to Parliament next session for a Provisional Order to supply Haslemere and some of the adjoining districts.

HOVE: *Application for Reduction in Price.*—The Hove Corporation has applied to the Board of Trade for a reduction in the prices charged by the Hove Electric Lighting Co. When the Provisional Order was transferred to the company in 1892 the Corporation was given certain rights in this matter, and they now state that the company, during the last seven years, have distributed dividends equal to an average of 10 per cent. per annum, and that, therefore, they were now entitled to put their rights into force. The company argue that the agreement with the Corporation entitled them to pay 10 per cent. not only upon the ordinary shares, but also upon the amount standing to the credit of the reserve fund. An inquiry into the matter began as far back as December, 1906, when it was decided by the inspector that the company had paid 10 per cent. dividend, and the present inquiry in London, before Mr. Sims Williams at the Surveyors' Institution, Great George-street, is mainly to fix the amount of the reduction. Mr. Robert Hammond and Mr. A. H. Dykes have given evidence on behalf of the Corporation. All the evidence and cross-examination was completed on Tuesday, and the final speeches will be made on a day to be fixed later.

HULL: *Telephones.*—At a meeting of the Corporation Telephone Committee last week, the extension of the telephone system from Cherry Burton to Wamme was approved.

JOHANNESBURG: *New Electrical Scheme.*—It is reported in the *Financial News* that a representative of Messrs. Beardmore is negotiating with a view to the establishment of a new electrical works in Johannesburg in competition with the Victoria Falls Power Co.

KING'S NORTON: *Tramways.*—The Tramways Committee have reported that the reconstruction of the Moseley and King's Heath routes have exceeded the estimates by £5,376. A credit balance of £4,000 exists in reference to the Pershore Road tramways undertaking, but as this is not available, it is proposed to approach the Local Government Board for sanction to an additional loan of £5,700.

LEICESTER: *Power Supply.*—The following rate for the supply of electricity to power consumers has been agreed to by the Council, on the recommendation of the Tramways Committee :—(*a*) The sum of 15s. per quarter for every horse-power in respect of the maximum horse-power required by the consumer, and (*b*) a sum of ¾d. for every Board of Trade unit supplied. These charges are subject to a scale of discount ranging from 10 to 15 per cent., according to the load factor in each case.

LEYTON: *The Electricity Undertaking.*—The District Council have had under consideration the charges for current, and in this connection have received a letter from the local Ratepayers' Association urging a reduction in the price and the need for the partial or entire abolition of meter rents. In the result it has been decided to adjourn consideration of any revision in the charges for current for six months, but meter rents are to be reduced from 1s. 6d. to 1s. per quarter. With regard to a suggestion that the Council should make fuller use of their powers with regard to the sale or letting for hire of motors, they do not consider the demand is sufficient to justify the expense which would be incurred in the organisation and the maintenance of a department for this purpose, especially as motor manufacturers are now prepared to supply motors on hire-purchase terms. A letter is to be sent to the Ratepayers' Association pointing out the economy which can be effected by the latest types of lamps which may be inspected at the Council's show-room. The freehold of the private road between the two portions of the electric light and power station is to be purchased from the owners of St. Patrick's Cemetery for a sum of £1,000. Messrs. Mather & Platt have written to the Council regretting that it is not possible to promise delivery of the new generator until about the beginning of September. The Electrical Engineer has been authorised to obtain some posters illustrative of the advantages of electricity, from the Associated Municipal Engineers (Greater London), who are prepared to supply these (80 in. by 60 in.) at 1s. 8d. each.

Tramway Inspector Summoned.—An inspector of the Leyton Urban District Council tramways was summoned at Stratford last week for acting as conductor without a licence, and Mr. Schofield, the tramway manager, was also summoned for knowingly allowing this to take place. The defence was that according to custom, if a driver or conductor was taken ill on the road, an unlicensed man could take his place for not more than 24 hours, and it was under the impression that he was acting in accordance with the regulations that the manager put the inspector upon the car. The Bench upheld this view and dismissed the summons.

LONDON: *Electric Lighting at the Tower.*—A curious dispute has arisen between the Stepney Borough Council and the City of London Electric Lighting Co. It appears that the company have maintained a supply to the Tower of London since September, 1905, although, strictly speaking, the Tower is within the borough of Stepney and outside the company's statutory area of supply. The company have been approached with a view to inducing them to withdraw the supply, but have declined to do so, and it is reported that legal proceedings are pending.

Bermondsey: Electric Lighting Audit.—In regard to a recent question in the House of Commons relative to the auditing of the accounts of the South London Electric Supply Corporation, the Electricity Committee has decided in favour of forwarding to the Government a communication protesting against the action of the Board of Trade, and also in favour of asking all other borough councils having electrical undertakings to take similar action.

St. Pancras: Electricity Accounts.—According to the accounts of the Borough Council's electricity undertaking, which have just been issued, the gross income for the year ended March 31st amounted to £77,602, an increase of £3,430 as compared with the previous year, which, after meeting all working expenses and the repayment of loans and interest charges, leaves a net profit of £9,454. This profit compares with £6,495 for the previous twelve months, the latter period having borne the cost of an action amounting to £3,585. On March 31st there was a credit balance on the net revenue account of £10,332, and this the Electricity and Public Lighting Committee has decided to carry forward as a working balance for the undertaking. The net balance in the reserve fund at the end of the year totalled

Digitized by Google

£29.541. The total capital expenditure of the undertaking at March 31st was £525,149.

Southwark: "Free" Wiring.—On October 30th last the Electric Light Committee reported on the progress made in wiring consumers' premises under the resolution of January 9th, 1907, and intimated that, owing to the success attending the scheme, it would be necessary, in order to meet demands of new consumers, to expend a further sum of £500 over the original amount estimated. The Committee on Monday reported having received a communication from the Electrical Engineer, stating that the sum now expended on the work amounts to £925, and that there are orders in hand which will increase the foregoing amount to about £1,250.

Woolwich.—At the meeting of the Borough Council on July 2nd, it was decided to issue 5,000 copies of a pamphlet with a view to stimulating the demand for electricity in the borough. Some time ago the L.C.C. sanctioned the borrowing of £820 for the installation of a cooling tower at Plumstead works. Owing to the many modifications in the arrangement of the plant the present cooling tower is considered to be of sufficient capacity to be worked in conjunction with the direct-current plant and the loan is therefore not required. The Council decided to rescind the resolution passed on October 17th, 1905, accepting the tender of Sugden & Co., at £820, for the supply of a cooling tower of 150,000 gallons capacity.—On a report by the Electricity Committee that "a definite application for electricity supply had been received in a district where, in the near future, there was every prospect of obtaining a large demand," the Council authorised the extension of the distributing mains at a cost of £150. The Committee stated that the applicant for current "occupies an important position in the electrical profession and is prepared to demonstrate the advantages of electricity supply to his neighbours."

OTLEY: *Electric Lighting.*—The Council has before it a notification of an application by private promoters for a Provisional Electric Lighting Order.

OXFORD: *Tramways.*—At a meeting of the City Council last week, it was decided after considerable discussion to affix the seal of the Corporation to a supplemental agreement between the City of Oxford & District Tramways Co., Ltd., and the National Electrical Construction Co., Ltd., and the City of Oxford Electric Tramways, Ltd.; and a deed of assignment between the City of Oxford and District Tramways Co., Ltd., and the Mayor, Aldermen, and citizens of Oxford.

SANTO DOMINGO: *Wireless Telegraphy.*—According to a Consular report, two wireless telegraphy installations are being set up on account of the Dominican Government by an American firm. One is situated on the sea front in this city, and will be of 20 kilowatt power, and the other will be erected at Santiago de los Caballeros, one of the principal towns of the Republic, situated on the Central Dominican Railway, about 40 miles from Puerto Plata. This latter installation is only to be of 2 kilowatt power. When in working order these wireless stations will communicate with San Juan de Porto Rico, Guantanamo, Jamaica, and the receiving station on the Florida coast. If these stations work satisfactorily they should prove a source of gain to the Dominican Government, and will considerably injure the interests of the Compagnie Française des Cables Télégraphiques, which enjoys a monopoly in cable communication with this Republic.

SEVILLE: *Electricity Supply and Tramways.*—According to a Consular Report, the German electric company (Compania Sevillana da Electricidad) still has a monopoly of the electric lighting of Seville and of the tramway lines, but there will shortly be a competitor in the recently formed Co-operativa de Electricidad, which will soon have completed elaborate works in the province of Malaga. Both companies are putting up extensive plant and offer to supply Seville and adjacent towns. The German company proposes to run tramways to two or three places within a radius of 10 miles. The new electric company will obtain power from a waterfall which they have acquired on the River Guadiaro. This project has the support of much local capital.

SHEFFIELD: *Electricity Accounts.*—Mr. S. E. Fedden issues his report on the accounts for the past year. The rapid increase in the consumption of energy for motive power is commented on, especially in the case of the introduction of electric driving in large works. The receipts for the year amounted to £78.554, and the working expenses to £25,344. After the payment of £48.394 for interest and sinking fund charges, a final surplus of £4.796 remains as compared with a surplus last year of £2.555 and a deficit the year before of £1,374. It is pointed out that the price of coal increased by an amount equivalent to 0·06d. per unit sold, and that if the price of coal had been the same as for the previous year, the surplus would have amounted to £7,280.

Report on Financial Position.—A short time ago the Electric Light Committee were desirous of borrowing £250.000, but the Finance Consultative Committee would not consent until a sub-committee had been appointed to ascertain the position of the undertaking, both financially and commercially. As a consequence, Sir Alexander Kennedy was asked to report, and in a statement concerning this report, the special sub-committee state that the sum actually paid by the Corporation to the old company was £268,147 plus £31,176 capital expenditure incurred by the company, whilst they were carrying on the business for the Corporation. Of this amount about 53 per cent. was unrepresented by any tangible asset, and it could only be looked upon as goodwill and the extra price for compulsory purchase. In addition to this sum, which amounts to £143.686, a further £51,554, representing obsolete plant taken over from the company, must be taken into account, and after considering other items, the committee are of the opinion that at least £202,996 of the total sum paid for the company's undertaking is not now represented by productive capital. Dividing the capital account so as to distinguish this sum from what might reasonably be taken as productive capital, and after taking into account sinking fund and depreciation, the productive capital is said to amount to £175,723, which it is thought will be wiped off in 30 years or less. Apart from interest and sinking fund, the undertaking has set aside £28,528, from which £2.200 has been taken for the purchase of motors and £10,000 towards renewals fund, leaving an unappropriated balance of £16,328. The sub-committee are of opinion that a further sum of £10,000 should be transferred to the renewals fund, leaving a balance of £6,628. Further, it is recommended that a sum of £5,000 per annum should be taken for the next five years from the working profits of the undertaking and placed to renewals fund, whilst the sub-committee further expresses the opinion that as soon as the finance of the undertaking permits, a reserve fund should be created up to 10 per cent. of the capital expenditure on the undertaking, as provided for in the Electric Lighting Acts. In his report Sir Alexander Kennedy discussed the question of whether the Sheaf Street station should be abandoned and the whole of the generation concentrated at Neepsend, and on the whole his opinion is in favour of the latter. The Special Committee generally praise the management of the undertaking.

Electric Wiring and Fitting.—A Special Committee of the Corporation recommend that in future the trading results of the electric wiring and fittings department should be published separately, after having a fair proportion of the management expenses debited to them.

SOUTHGATE: *Proposed Supply Schemes.*—The District Council has received a letter from Messrs. Foote & Milne giving notice of intention to apply to the Board of Trade for a Provisional Order for electric lighting. At the last meeting of the Council the General Purposes Committee reported that they had under consideration two schemes for electric lighting—one for taking electricity in bulk from the North Metropolitan Company and distributing same in the district, and the other a proposal by the company for the transfer to the company of the Council's electric lighting order under certain conditions to be agreed upon. The Committee announced that at present they were unable to make any recommendation.

SOUTHAMPTON: *Electric Supply Extension.*—The Electricity Committee have resolved to give notice to the South Stoneham Rural District Council of their intention to apply for a Provisional Order for the supply of electricity in that district.

SWANSEA: *Telephones.*—Notice has been given by the National Telephone Co. of a revision of rates on the expiration of present contracts. The new rate for business purposes and residences is a minimum charge of £5 covering 500 calls, or a larger number of calls may be contracted for at the following rates:—From 500 to 1,000 (in blocks of 250), 8s. per hundred; 1,000 to 2,000 calls (in blocks of 250), 6s. per hundred; 2,000 to 4,500 calls (in blocks of 300), 4s. per hundred. Excess calls, when the number contracted for is 1,250 or less, will be charged for at 2d. each, and over 1,250 at 1d. each. There will also be a special unlimited rate of £8 per annum for residence purposes only within one mile of the exchange.

TONBRIDGE: *Electricity Loan.*—Criticism is being made locally upon the fact that the Local Government Board has been such a long time in fixing the date for the inquiry into the proposed loan for the extension of the electric lighting plant, and it has been decided to ask Mr. A. P. Hedges, M.P., to use his influence at Westminster to help matters forward.

WARRINGTON: *Electricity Accounts.*—The report and statement of accounts of the Town Council's electric supply undertaking for the year ended March 31st, 1908, shows that the result of the twelve months' working, after paying interest and redemption of capital, was a profit of £2,213, as compared with £2,516 for 1906-7. The capital expenditure was increased during the year from £86,522 to £92.085. The total revenue reached £17.234, as compared with £16.238 in the previous year, the amount received from the supply of electricity being £16.652, as compared with £15,616. The cost of generation and distribution totalled just over £9.700, as compared with a little more than £8,528 in 1906-7. The gross profit was £7.533, as against £7.709, and the percentage of costs to revenue 56·28 as against 52·52. The capital redeemed to date increased during the twelve months from £8.545 to £10,913, the percentage of capital redeemed to amount spent increasing from 9·87 to 11·85. The number of 8 c.p. lamps shows increase from 64.711 to 77.878 (excluding tramways), and the number of units sold (also excluding tramways) advanced from 1.839.912 to 2.064.996. The revenue per lamp last year was 4s. 5d. as compared with 4s. 10d. in 1906-7. The average prices obtained were

Digitized by Google

as follows:—Public, 1·90d. (as against 2·07d.); private, 1·51d.; traction, 1·50d. (the two last-mentioned figures being the same as for the previous twelve months).

WILLESDEN: *Electricity Accounts.*—The statement of accounts of the electricity undertaking of the Urban District Council for the year ended March 31st, 1908, shows a gross profit for the year of £8,198, and a net profit of £725, the actual surplus on the electricity fund (after allowing for deficiency in previous years) being £182. The Electricity Committee has decided that £337 be written off as irrecoverable, including bad debts amounting to £259, and £32 for provision in respect of outstanding accounts.—The Board of Trade has consented to the Council altering the system of supply from direct to alternating current in part of the area of supply.—Consideration of a communication as to the charges for arc lighting to private consumers has been deferred until after the completion of negotiations with the North Metropolitan Electric Power Supply Company with regard to a reduction in the prices charged for bulk supply.

WORCESTER: *Electricity Accounts.*—The annual report of Mr. C. M. Shaw for the period of fifteen months ended March 25th last gives the total revenue as £20,775. The total working costs were £8,626, leaving a gross profit of £12,149, which, after payment of interest and sinking fund charges, leaves £1,694 to be carried to appropriation account. Of this £192 was used to clear off the outstanding deficit from last year, and £1,149 was applied to capital expenditure, leaving a final surplus of £352. Several new customers have been connected during the year, the total connections now amounting to the equivalent of 10,877 8 c.p. lamps. As will be seen in the Paper by Mr. C. M. Shaw, the City Electrical Engineer, published in our report of the I.M.E.A. meeting, this week, the system has been reconstructed, and the water supply has been augmented by the surrender of two water-wheels by the Worcester Royal Porcelain Co. The result is that the works costs have been reduced from 1·076d. to 0·889d. per unit sold, and the coal costs from 0·53d. to 0·397d., in spite of an increase of between 25 and 30 per cent. in the price of coal.

YORK: *Light Railway Order.*—The Light Railway Commissioners have submitted the York Light Railway Order to the Board of Trade for confirmation, and objections must be lodged by the 16th inst.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Miscellaneous

AUSTRALIA.—The following tenders are required by the dates specified for telephone material:—South Australia, August 26th: 9 tons wire, copper, hard drawn (200 lb. to the mile); 3,000 tapes, copper, for 200 lb. wire and No. 5 insulators; 3,000 binders, copper, for 200 lb. wire and No. 5 insulators; 3,000 insulators, porcelain, No. 5. New South Wales, August 5th: 69 tons wire, hard-drawn copper (300 lb. per mile); 1 ton tape, binding copper (200 lb. per mile); 15,000 insulators, best white porcelain, large. August 12th: Supply, delivery, and erection of a branching metallic multiple magneto switchboard, at the Mosman Telephone Exchange. Western Australia, September 7th: 1 common battery switchboard of nine sections in all (for Fremantle), together with all associated frames, racks, power plant, and parts; 650 telephone wall sets, 150 telephone table sets, 800 protectors, 90 extension switch and bell sets, complete, 30 switchboards for 4 lines, 20 switchboards for 6 lines, 5 switchboards for 12 lines, 5 switchboards for 24 lines, 20 telephone wall sets for party lines, 10 telephone table sets for party lines. Tenders are also required by August 26th for installations of wireless telegraphy. Tender forms, specifications, &c., may be obtained at the Commonwealth Offices in London, 72 Victoria Street, S.W., where also preliminary deposits on tenders may be paid.

COLOMBIA.—The *Diario Oficial* of Colombia contains copies of decrees granting concessions to Señor E. Drescoes, of Perreira (Department of Caldas), and the Bucaramanga Gold and General Mining Company, Limited, and the Francia Gold and Silver Company, Limited, for the construction of telephone lines, the former from Perreira to his property El Tablazo, and the latter between the places named La Tronadora, Francia, Vetus, La Baja, and Libertador in the Province of Soto (Department of Santander).

DERBY.—The Tramways Committee have decided to extend the tram terminus at the Midland Railway Station.

LONDON COUNTY COUNCIL.—The Council invite tenders for six electrically propelled stores transport vehicles. Full particulars from the Clerk (fee, £2 returnable), and tenders by July 21st.

WILLESDEN.—The Council's Electrical Engineer has been instructed to invite tenders for the painting of arc-lamp columns, feeder pillars, and plant, &c., at the electricity works.

Generating Stations, Sub-stations, Mains, &c.

BO'NESS.—In consequence of a report by the National Electric Construction Co. on the increasing demand for electric supply, the Town Council have decided to proceed with extensions at an estimated cost of £6.000, subject to the sanction of the Secretary for Scotland to a loan for this amount.

COVENTRY.—A Local Government Board inquiry was held last week into an application by the Corporation for sanction to borrow £35,000 in connection with the electric lighting undertaking. This expenditure is necessitated in consequence of the extension of the area of supply granted recently by Parliament, and the first portion of the expenditure will be chiefly in mains.

CROYDON.—Application is to be made to the Board of Trade for sanction to a loan of £540 for carrying out the construction of a single line of tramway connecting two loops in North End. The Borough Road Surveyor's estimate for carrying out the work is 120 yards lineal single track complete at £4 10s., giving a total of £540.

The Corporation is to invite tenders for mechanical stokers to be fitted to two additional boilers at the electricity works. The estimated cost for apparatus, fitting, and necessary alterations is £620.

LEYTON.—A letter has been received from the Chief Engineer of the London County Council to the effect that the necessary arrangements are being made for putting in hand the work in connection with the reconstruction of the line recently purchased from the Lea Bridge, Leyton, and Walthamstow Tramways Company. With regard to the electrical equipment, the Tramways Manager of the L.C.C. has suggested, for the purpose of avoiding unnecessary cost and delay, that the work be carried out by the Leyton Council's electricity department, and this has been provisionally agreed to, the price to be charged being the actual cost plus 10 per cent. for supervision. The Leyton Electrical Engineer has been authorised to obtain quotations for the materials required.

KENDAL.—The Electricity Committee has resolved to recommend the Corporation to apply to the Local Government Board for a loan of £10,000 for the erection of a generating station at the canal head, in conjunction with a refuse destructor. The amount is made up as follows:—Buildings and machinery, £5.250; meters and distributing mains, £1,000; future extensions, £3,750; total, £10,000.

LONDON: *London County Council.*—The Highways Committee recommend that the portion of the Nine Elms Lane to East Hill, Wandsworth, tramways, between East Hill and Falcon Road, be converted to electric traction on the underground conduit system, at an estimated cost of £35,790. The length of the portion of the road in question is $\frac{7}{8}$ of a mile, and details of the estimate are as follows: Track work, &c., including special work and £4,000 for rails, £29,000; cables and feeder pillars, £830; cable ducts, £1,130; sub-station plant, £80; and rolling stock, £4,750.

The Highways Committee also recommend the reconstruction of the tramways from Euston Road via Camden Road to Holloway Road for electric traction upon the underground conduit system at an estimated capital outlay of £173,730. There was an intention of adopting the G.B. surface contact system upon this route, but the Committee state that, in view of the fact that the working of the lines reconstructed on that system from Whitechapel to Bow Bridge has only just been commenced, sufficient experience will not be available to enable them to decide whether they could recommend the adoption of the G.B. system. The length of the tramways from Euston Road to Holloway Road is about $2\frac{3}{4}$ route miles. Details of the estimate are as follows: Track work, &c., including special work and £12,500 for rails, £105,000; cables, £18,600; feeder pillars, £320; cable ducts, £10,220; sub-station plant, £15,840; rolling stock, £23,750.

Battersea.—In order to meet applications for the supply of electrical energy, the Lighting Committee has decided to extend mains and lay services, at an estimated cost of £45.

Islington.—The Council is to provide and lay a distributing main, at an estimated cost of £85, to supply electricity for lighting at premises of the Home and Colonial Stores, Ltd., in Blackstock Road.

Poplar.—The Finance Committee of the County Council recommend that a loan be granted to the Borough Council of £22.180, repayable on the instalment system as to £300 for foundations and boilers, and £887 for erection of a sub-station within 50 years, as to £600 for mains within 30 years, as to £14.493 for machinery within 20 years, as to £250 for house services within 12 years, and as to £250 for meters within 10 years.

Woolwich.—It has been decided to apply to the London County Council for loans for the following purposes:—Mains: Hippodrome feeder, £610; Ray's Wharf extension, £226; Wood Street extension, £680. Plant: Oil-eliminating plant, £309 10s.; motor alternator, £784 10s. Total, £2.610.

ST. ANNE'S.—Mr. A. W. Ducat held a Local Government Board inquiry last week into an application for a loan of £3.500 for cables and extensions.

Digitized by Google

YORK.—The Electricity Committee has instructed the engineer to obtain tenders for the supply of carbon brushes, meters, and motor-starters for two years, and stores and coal for one year.

Wiring

LONDON.

E.—Mr. S. D. Adshead, architect, of 46 Great Russell Street, W.C., has prepared plans for the erection of a building on the east side of Betts Street, St. George's-in-the-East.

A building is to be erected in Ben Jonson Road, Stepney, by Mr. E. Jackson, builder, 10 Whitehorse Lane, Whitechapel.

The London County Council has decided to erect a manual training centre in connection with the Woolmore Street (Poplar) School. The architect to the Education Committee is Mr. T. J. Bailey, Spring Gardens, S.W.

N.W.—Messrs. Howell J. Williams, Ltd., builders, 11-17 Bermondsey Square, S.E., are to erect shops, &c., in Hampstead Road.

Flats are to be erected in East Heath Road, Hampstead Heath. Builder, L. E. Hookway, Beaufort Mansions, Chelsea, S.W.

Earges Hotel, 2-3-4 Liverpool Street, King's Cross, is to be rebuilt. Builders, Higgs & Hill, South Lambeth Road.

Mr. H. Shaw, architect, of 60 Nicholl Road, Willesden, has prepared plans of a shop and house in High Road, Willesden, and of a show-room in Craven Park Road, Willesden.

Alterations to the Keble Memorial School, Crownhill Road, Harlesden, are to be carried out for the Rev. Mother Superior. Architects, Keble & Dickie, 466 Oxford Street, W.

Three shops are to be erected in Walm Lane, Willesden Green Station, for the Metropolitan Railway. Builders, J. Grover & Son, 79 Shepperton Road, N.E.

Messrs. Callow & Wright, Ltd., builders and estate agents, of Brondesbury Park, N.W., are to erect six houses in Chamber Lane, Willesden.

It is intended to erect two houses on Shoot Up Hill, Cricklewood. Builders, H. B. Oldrey & Sons, 7 West End Lane.

A new sub-station (£4,950) is to be erected at Camden Town. Mr Maurice Fitzmaurice, C.M.G., the Chief Engineer to the L.C.C., Spring Gardens, S.W.

S.E.—The London County Council will erect a superintendent's house at the Rotherhithe Tunnel. Architect, Mr. W. E. Riley, Spring Gardens, S.W.

Five shops and dwelling houses are to be erected in Old Kent Road, S.E. Architect, Mr. F. W. Foster, 41 Bedford Row, W.C.

Twenty-seven houses are to be erected on the south side of Straightsmouth. Architect, Mr. A. Roberts, 92 London Street, Greenwich.

Additions are to be carried out at St. Ann's School, Greenwich, S.E. Contractors, Messrs. Bendon, Ltd., 48 Chancellor Road, Hammersmith.

The Postmaster-General has decided to establish a post office in the High Street, Plumstead. Plans are to be prepared at H.M. Office of Works, Storey's Gate, S.W.

A vestry and additions are to be made to Christ Church, Shooters Hill. Contractors, Messrs. Kirk & Randall, of Warren Lane Works, Woolwich.

W.—A new residence (£3,600) is to be erected for Sir Lewis McIver, Bart., M.P., by Mr. H. L. Holloway, builder, Church Street, Deptford, S.E. Architect, Mr. R. Gardner Hammond, 16 Essex Street, Strand.

The Lion Brewery Co., Ltd., are to re-erect the "Queen Adelaide" public-house, and also four shops in Uxbridge Road, Hammersmith. Architect, Mr. C. G. Miller, 65 Chancery Lane, W.C.

PROVINCES.

BACUP.—It is intended to erect a school in the Weir district. Architects, Butterworth & Duncan, South Parade, Rochdale.

BIRMINGHAM.—The Corporation are obtaining tenders for the erection of a laundry in Woodcock Street. The estimated cost of the whole building is £1,700.

BRISTOL.—Mr. Edward Gabriel, architect, 42 Old Broad Street, E.C., has prepared plans for the erection of buildings at Southmead, for the Committee of the School of Industry for the Blind.

CARDIFF.—Messrs. T. Owen & Co., Ltd., of Cardiff, are erecting a large paper factory in that town, and also a capacious institute for their employees. Architect, J. William Rodger, 14 High Street, Cardiff.

CHELMSFORD.—Plans have been prepared by Mr. W. Hayne, architect, of Frinton-upon-Sea, for a Baptist Chapel and class-rooms, with a seating accommodation of nearly 600. It has been decided that the buildings be lighted by electricity.

CLEETHORPES (Lincs.).—Additions are to be made to the County Schools, Elliston Street, at a cost of £4,180. Architects, Scorer & Gamble, Bank Street Chambers, Lincoln; builders, H. S. & W. Close, Brayford Wharf, Lincoln.

CROWBOROUGH (Sussex).—The Hon. Mrs. Brougham is having a residence erected at Crowborough, at a cost of £2,770. Architect, R. G. Hammond, 16 Essex Street, W.C.; builders, Connor Bros., of Crowborough.

DARTFORD.—Foundation stones have been laid of a new Wesleyan Church at Greenhithe. Architect, Sydney W. Neighbour, 9 Regent Street, S.W.; builders, Brown Bros., of Grays.

DURHAM.—The North Eastern Railway Co. have decided to carry out extensions to their machine shop at Shildon Wagon Works. Architect, William Bell, Toft Green, York.

ELTHAM.—Additions are to be carried out at the Holy Trinity Church, Southend Road, for the vicar and churchwardens. Builders, J. Dorey & Co., of Brentford.

ENFIELD.—Mr. H. G. Crothall, architect to Education Committee of Middlesex County Council, Guildhall, Westminster, S.W., has prepared plans, &c., for the erection of extensions to Enfield Boys' Grammar School. The estimated cost of the work is about £6,000.

GILLINGHAM.—Tenders are invited for the installation of electric light at Byran Road, Barnsole Road, and Richmond Road Council Schools for the Education Committee. Particulars from Mr. Andrew Johns, Secretary, 4 Gardiner Street, Gillingham, fee 10s. 6d. returnable, and tenders by July 17th.

HIGH WYCOMBE (Bucks.).—The Union Baptist Church is to be rebuilt at a cost of £5,000. Architect, Thomas Thurlow, High Street, Northampton; builder, Richard Cleaver, Wood Street, Northampton.

LEYTON.—The Leyton Education Committee has resolved to erect two-storey block buildings in Sybourn Street, and blocks of buildings in Canterbury Road, or the purposes of school accommodation.—The Leyton Public Health Committee has decided to provide additional hospital accommodation at a cost of £650. Mr. W. Dawson is the Council's surveyor.

LINCOLN.—Additions are to be carried out by the Town Council at the infectious diseases hospital.

LIVERPOOL.—The Corporation has provisionally decided to erect baths at an estimated cost of £5,000. The Clerk to the Surveyor's Department is Mr. W. Hayward.

LUTON.—Messrs. T. & E. Neville, builders, of 30 Castle Street, are erecting Baptist Schools and Institute, Wellington Street. Architects, Messrs. George Baines & Son, 11 Clement's Inn, Strand, W.C.

MANCHESTER.—The Guardians are to erect a block for the accommodation of imbeciles at their workhouse at Crumpsall. Architect, Mr. A. J. Murgatroyd, 23 Strutt Street, Manchester.

MIRFIELD (YORKS).—The Mirfield Reformatory School Committee have decided on a school at Calder Farm. Architect, Mr. Joseph Berry, 3 Market Place, Huddersfield.

NORTHAMPTON.—The County Surveyor is instructed to prepare plans for the erection of St. Katherine's School.

NOTTINGHAM.—The County Education Committee has approved plans for the erection of a school. The estimated cost is £10,000.

OXFORD.—Mr. T. G. Jackson, R.A., of 14 Buckingham Street, Strand, is the architect for a new laboratory at the University.

PORTSMOUTH.—Mr. W. Bates White, architect, 173 Fawcet Road, Southsea, has drawn up specifications and plans of proposed new warehouse, depository, &c., &c.

PRESTON.—The Town Council proposes to erect a school at Deepdale, Engineer and surveyor, Mr. T. Cookson. Cost of work abut £13,000.

RAMSGATE.—A new general hospital and seamen's infirmary has just been commenced in West Cliff Road. Architect, Messrs. Wood and Ainslie.

SLOUGH.—The foundation-stone has been laid of a new Catholic Church in Curzon Street. Architect, Mr. Benedict Williamson; builders, Messrs. Godson & Sons, Kilburn Lane, London, N.W.

SOUTHAMPTON.—A new Council school is to be provided at Ringwood. County Surveyor, Mr. W. J. Taylor, The Castle, Winchester.

SOUTH SHIELDS.—A school is to be erected at Mowbray at a cost of £6,885. Builders, Messrs. Stephen Sherriff & Sons, Back Woodbine Street, South Shields.

STOCKPORT.—A new school is to be erected at Hazel Grove, with a seating capacity of 800, by the Cheshire Local Education Authority. J. W. Bain, Clerk.

SUTTON.—Additions are to be carried out to the Banstead Asylum by the London County Council at an estimated cost of £2,700. Architect, Mr. W. E. Riley, Spring Gardens, S.W.

WORCESTER.—The foundation-stone of a new Congregational Church at King's Norton has recently been laid. Architects, Messrs. Ewen Harper & Brother, Ruskin Chambers, 191 Corporation Street, Birmingham.

Kent Collieries Electrical Plant.—On Tuesday, in the Divisional Court, before the Lord Chief Justice and Mr. Justice Ridley, Mr. Bousfield, K.C., made an application in the case of Messrs. Ernest Scott & Mountain, Ltd., of Newcastle and Gateshead, against the Kent Collieries, Ltd. Counsel applied for a stay of execution, pending an appeal. Judgment had been given on the claim and counterclaim against the defendants for £1,826 (see ELECTRICAL ENGINEERING, Vol. III., p. 987). Mr. C. A. Russell, K.C., for the plaintiffs, asked that the stay should be granted on condition that the money be paid into Court. Their Lordships granted the stay asked for on condition that the amount mentioned should be paid into Court.

TENDERS RECEIVED AND ACCEPTED

BELFAST.—The following tenders for coal have been accepted :—Mr. John Kelly, 10,000 tons; Messrs. Howden & Charley, 5,000 tons; Messrs. M'Elroy & Son, 5,000 tons; Messrs. J. R. Noble, 2,500 tons; and the Antrim Iron Ore Co., 2,500 tons.

BURNLEY.—The Town Council has completed an arrangement for the purchase of five covered-top electric cars.

At the meeting of the Town Council on July 2nd, Councillor Grey, in moving that the Electricity Committee purchase a 750-kw. generating set at a price not exceeding £6,000, said it was not expected that they would actually spend so much. The resolution was carried.

At the same meeting it was explained that the Klein Engineering Co., of Manchester, whose tender had been accepted for the erection of a cooling tower at the electricity works, had gone into liquidation, and with the consent of the company Messrs. Riley, Ltd., of Fleetwood, would supply the tower for £123 10s.—£6 10s. less than the other. The Council sanctioned the arrangement.

CROYDON.—The Corporation has accepted the tender of Babcock and Wilcox, Ltd., at £143, for the supply of materials for alterations to feed mains.

DARTFORD.—The tender of Messrs. Johnson and Phillips for £159 for house service cable jointing materials and accessories has been accepted.

DERBY.—Tenders for the supply of coal from the Derby Coal Co., Ltd., Messrs. T. & G. Walker, and Messrs. Parsons Bros. have been accepted. The tender of Messrs. E. Morley & Son for fixing a weigh bridge at the electric power station has also been accepted.

HORNSEY.—The Education Committee has decided to accept the tender of F. Cottrell, at £179 2s. 10d., for installing electric light at North Harringay Schools.

LANCASHIRE.—The British Westinghouse Electric & Manufacturing Co., Ltd., have received an order from Messrs. Tweedales & Smalley, Castleton, Lancashire, for one of their latest type tandem vertical gas engines, to be direct coupled to a direct-current generator of a combined capacity of 500 kw. when running at 110 volts, with switchboard complete, forming an extension to the 235-kw. gas-engine sets recently put into operation.

LEYTON.—The Urban District Council has accepted the following tender of Messrs. Venner & Co. for the supply of ordinary meters for the electrical department for the year ending June 30th, 1909 :—

Size.		Price. £ s. d.
1½	amperes	1 13 0
3	,, ...	1 16 0
5	,, ...	2 0 0
10	,, ...	2 5 0
18	,, ...	—
25	,, ...	2 10 0
50	,, ...	2 14 0
75	,, ...	—
100	,, ...	3 3 0

These prices are the same as those accepted last year, and similar prices were quoted this year by Ferranti, Ltd. (who also quoted £2 10s. for 18 amp. and £3 3s. for 75 amp.), and the British Thomson-Houston Co. The latter firm did not, however, quote for 25, 50, 75, and 100 ampere meters. Like Messrs. Ferranti, they quoted £2 10s. for the 18 ampere meter. The Council have also accepted the tender of Myers, Rose & Co., Ltd., for the annual supply of hand-picked, small, hard steam coal (Linby, Newstead, and Annesley) at 16s. 5½d. per ton respectively. The coal is to be taken from either colliery at the contractors' option, subject to the Council having the option to take a supply of slack, in addition to, or in lieu of, the above-mentioned coal, if considered desirable by the Electrical Engineer at any time for use with the mechanical stoker, such slack to be supplied by Myers, Rose & Co., at the following prices :—Bolsover nutty, 12s. 11d.; Creswell nutty, 12s. 11d.; Mansfield nutty, 11s. 10d.; Bentick, 12s. 7d.; West Hallam, 11s. 8d.; Shipley, 10s. 11d.; and Cossall, 11s. 8d.

LONDON: *London County Council.*—The tender of Mr. A. L. Holloway, builder, Union Works, Church Street, Deptford, S.E., for the reconstruction of the engine-house block of the chief fire station, Southwark Bridge Road, has been accepted at £3,653.

The Highways Committee recommend that a sub-station at Camden Town be erected without the intervention of a contractor, and that the wiring and fittings for the electric lighting be also carried out by direct labour. The Works Committee are prepared to erect the building at £4,175, to which is added the sum of £775 for professional and incidental expenses. The wiring and fitting will be carried out at a cost of £150.

An agreement has been entered into with Messrs. Southwood, Smith & Co., to sell the edition of 100,000 copies of the tramways guide which the Council is issuing at a commission of 55 per cent. The total receipts are put at £412 10s., so that the Council will receive £185 12s. 6d.

The undermentioned tenders have been received for the supply of ten hydraulic jacks for use in the pits at the various car sheds :—

National Rail and Tramway Appliances Co. (Recommended.)	£34 4 each.
F. W. Rowlands & Co.	35 10 each.
Watlington & Co.	36 15 each.

The following tenders have been received for the road work and plate laying for the reconstruction upon the underground conduit system of the Dulwich Library to Forest Hill tramways :—W. Manders, Leyton (recommended), £27,431 10s. 1d.; John Mowlem & Co., Ltd., Westminster, £28,120; Dick, Kerr & Co., Cannon Street, £28,126 6s. 7d.; Robert W. Blackwell & Co., Ltd., Westminster, £28,459 8s. 9d.; Fry Bros., Greenwich, £29,992 17s. 2d.; J. G. White & Co., Ltd., Cannon Street, £30,277 13s. 6d.; W. Muirhead & Co., Queen Victoria Street, £31,613 6s. 6d.

For the supply of feeder pillars during 1908-9 the London County Council have received the following tenders :—

	£ s.
J. H. Tucker & Co. (recommended)	1,595 6
Robert W. Blackwell & Co.	1,718 16
Spagnoletti, Ltd., ...	1,762 3
The Edison & Swan United Electric Light Co., Ltd.	1,782 3
British Insulated & Helsby Cables	1,818 16
,, ,, (Alternative tender)	1,841 11
,, ,, ,,	1,896 3
Thomas L. Scott & Co., Ltd.	1,831 3
W. Boydell & Sons, Ltd.	1,877 16
Universal Electric Manufacturing Co., Ltd.	1,897 19
Estler Brothers	1,901 2
Johnson & Phillips, Ltd.	1,911 7
Nalder Brothers & Thompson, Ltd.	1,951 17
Callender's Cable & Construction Co., Ltd.	2,117 19
W. T. Glover & Co., Ltd.	2,445 18
Whipp & Bourne	2,597 16

Battersea.—The Lighting Committee has decided to accept the tender of Babcock & Wilcox, Ltd., at £220, to carry out work in connection with rearrangement of the boiler-house steam-range at the central electricity station.

Hampstead.—The experiment of using a Berry series gear in one of the sub-stations having proved successful, the Council at the last meeting decided to fix similar equipment in all the other sub-stations, and also a number of new transformers, the whole to cost £688.—Only a small quantity of water has been obtained from the artesian well sunk some years ago at a cost of £1,100, and at present £1,000 per annum is paid for water supplied. Messrs. Isler & Co. have made an offer to endeavour to obtain a supply of water from the well by a process of their own. If they obtain two thousand gallons per hour they will receive £321 10s., if four thousand gallons £521 10s.; but if they are unsuccessful only £36 10s. is to be paid to them. This offer was accepted.

Islington.—Necessary repairs to an artesian well pump at the Borough Council's electricity works are to be carried out by the New Calyx Drill & Boring Co., at £88 11s.

St. Pancras.—The Borough Council Electricity and Public Lighting Committee has received the following tenders for a portion of pipe-work in connection with new machinery at the King's Road generating station :—

John Spencer Ltd. (provisionally accepted)	£235 0s. 0d.
Edward Le Bas & Co.	£297 10s. 0d.
John Fraser & Son	£486 0s. 0d.

Westminster.—The City Council Baths and Washhouses Committee has accepted the tender of Belshaw & Co. at £16 18s. for the provision of additional switches to the electric light installation at the Buckingham Palace Road Baths. There were seven tenders received, ranging from the amount of that of Messrs. Belshaw to £34 2s.

MOSCOW.—It is stated that orders to the value of £83,000 have been placed by the municipality with Messrs. Dick, Kerr & Co., and the British Insulated & Helsby Cables, Ltd., for the equipment of the Moscow electric tramways.

PLYMOUTH.—The tender of Messrs. Cory Brothers, Ltd., of Cardiff, for the supply of 7,500 tons of coal at 13s. 1½d. per ton, has been accepted. The price of the last cargo of 1,000 tons was 14s. 1½d. per ton.

PORTSMOUTH.—The tender of Messrs. W. Kennedy, Ltd., of Partick, has been accepted for the construction of the transporter bridge in connection with the electric light railway between Portsmouth and Hayling Island. The bridge will be of sufficient height to allow warships to enter the harbour.

WILLESDEN.—The Electricity Committee of the U.D.C. has resolved to accept the tender of the British Westinghouse Electrical & Manufacturing Co., Ltd., for the supply of a converting plant.

YORK.—The tender of Messrs. Callender's Cable & Construction Co., at £334 16s., has been accepted for a cable to be laid across the River Ouse at Skeldergate Bridge.

PARLIAMENTARY INTELLIGENCE

LONDON ELECTRIC POWER BILLS.—Our report of the final proceedings before Lord Cromer's Committee, dealing with these Bills, will be found on page 69.

DISTRICT RAILWAY BILL.—This Bill was before a Committee of the House of Commons, presided over by Sir Lewis McIver. The Bill, which has already passed the House of Lords, proposes to authorise the issue of £750,000 prior lien debentures to meeting existing and prospective liabilities. It was anticipated that this amount could be issued at 4 per cent., but the limit in the Bill was 4½ per cent. The first use of the new capital will be to pay off existing mortgages of £478.000, the interest upon which is £20,000. Probably £500.000 or £600.000 will be raised at once, and the remainder spread over a number of years. Recognising that the scheme was in the interest of the company as a whole, it was stated to the Committee that 8 per cent. of the debenture holders had expressed their assent to it. If some such scheme were not carried out, the interest on the debenture stock must fall into arrears, and an application might have to be made for the appointment of a receiver, with results disastrous to the future of the company. The Committee found the preamble of the Bill proved.

INFECTION FROM TELEPHONES.—In the House of Commons on Monday Sir Edward Sassoon asked if the Postmaster-General was now in a position to say that the telephone company should be called upon to adopt the flat mouthpiece, such as was allowed abroad, instead of the present "antiquated" instrument, in the interests of hygiene and cleanliness. The Postmaster-General stated that he had no powers to force the National Telephone Co. to adopt any particular form of telephone. The standard instruments now in use were those considered efficient by all experts in this country and in the United States, and it was an easy matter for a subscriber to keep his instrument in a clean and sanitary condition.

SOUTH WALES ELECTRICAL POWER DISTRIBUTION BILL.—A Committee of the House of Commons, presided over by Mr. Partington, passed the preamble of this Bill last week. We gave full particulars of the measure when it was before the Committee of the House of Lords. Briefly, the Bill proposes to make arrangements with the company's creditors by the issue of £150 of preference shares for every £100 of debt, and also to confirm arrangements with the debenture holders, and further to ratify agreements with regard to the disposal of the generating stations of the company.

PATENTS ACT.—In answer to a question in the House of Commons last week, Mr. Churchill said that representations had been received from the United States and German Governments in respect of Section 27 of the Patents and Designs Act of 1907, which limits the time during which the patents must be worked in this country. His Majesty's Government, however, had no intention of proposing fresh legislation, nor to extend the time limit under the section of the Act in question.

PROGRESS OF ELECTRICAL BILLS.—The Paisley and District Tramways Order Confirmation Bill was read a third time in the House of Commons on Monday.

The Finchley Urban District Council Bill and the Motherwell Borough (Extension) Bill, were read a third time in the House of Lords on Monday.

The Macclesfield and District Tramways (Abandonment) Bill and the Tramways Order Confirmation Bill No. 2, were read a third time in the House of Lords on Monday.

The Bristol Tramways Bill was read a third time in the House of Commons last week.

UNOPPOSED BILLS.—The Nottinghamshire and Derbyshire Tramways No. 2 Bill was before the Unopposed Committee of the House of Commons on Tuesday, and was ordered to be reported for third reading.

London County Council Tramways and Improvements Bill was ordered to be reported for third reading by the Unopposed Committee of the House of Commons on Tuesday.

WIRELESS TELEGRAPHY IN THE NAVY.—In answer to some questions in the House of Commons last week, Mr. Lambert said that the Admiralty had not yet found any system of wireless telegraphy, which could not be tapped by other ships and stations possessing suitable instruments; neither had the Admiralty knowledge of any system which required less horse-power than the one now used to secure reliable communication.

MISCELLANEOUS CITY NOTES

BRITISH ALUMINIUM CO.—Applications are being invited for an issue at par of £700.000 five per cent. redeemable mortgage debenture stock, which will be secured by a trust deed giving a specific charge upon all the freehold and leasehold properties of the company and a floating charge upon the undertaking, except unpaid capital, subject only to £230.745 five per cent. first mortgage debenture stock. The prospectus states that when all the company's undertakings are completed, which it is hoped will be at the end of next year, it is expected that there will be 60.000 h.p. available for the company's operation. During the three years which have elapsed since the Foyers water-power scheme was completed, the profits of the company (after deducting interest on the debentures and debenture stock or depreciation) have been as follows :—1905, £93,296; 1906, £155,023; 1907, £120,481. Works have now been started at Stangfjord in Norway, and also at Kinloch Leven.

CITY OF LONDON ELECTRIC LIGHTING CO.—Warrants in payment of the half-year's interest to the 30th ult., on this company's £400,000 5 per cent. first and £300,000 4½ per cent. second debenture stocks have been posted.

At the meeting held on the 1st inst. the directors declared the following dividends on account of the distribution for the year ending December 31st, 1908. On the company's preference shares, six shillings per share being at the full rate of 6 per cent. per annum for the half-year ended June 30th, 1908. On the company's ordinary shares, five shillings per share being at the rate of five per cent. per annum for the half-year ended June 30th, 1908. The above dividends will be subject to the deduction of income tax, and will be payable on or after August 1st, 1908, to all shareholders registered on the books of the company on July 17th, 1908.

COMPANIES STRUCK OFF REGISTER.—The names of the following electrical companies will be struck off the register, and the companies dissolved at the expiration of three months, unless cause be shown to the contrary: Electrical Appliances Syndicate, Ltd., Electrical Productions, Ltd., Electro-Smelting Co., Ltd., Helios Electrical Construction Co., Ltd., Irish Electric Railways Co., Ltd., North-West London Electric Supply Co., Ltd., Uddingston District Electric Lighting Co., Ltd.

CONSOLIDATED ELECTRICAL CO.—A dividend of 3½ per cent., less income tax, is recommended upon the ordinary shares for the year ended March 31st, 1908.

EASTERN EXTENSION, AUSTRALASIA, & CHINA TELEGRAPH CO.—An interim dividend for the quarter ended March 31st last of 2s. 6d. per share has been declared.

EASTERN TELEGRAPH CO.—A dividend at the rate of 1¼ per cent. has been declared on the ordinary stock, free of tax, in respect of the current year.

ELECTRICAL POWER STORAGE CO.—A 5 per cent. dividend is recommended on the ordinary shares for the year ended May 31st, 1908.

ELECTRIC TAXICAB CO.—Subscriptions are invited by the Electric Taxicab Co., which has been registered with a capital of £300,000 divided into £1 shares, the whole of which is now offered to the public. We give some technical particulars of the vehicles which it is proposed to put upon the streets on page 49, and the prospectus appears in our advertisement columns.

GREAT NORTHERN TELEGRAPH CO.—An interim dividend of 5 per cent. less income tax has been declared for the past half-year.

HASTINGS & DISTRICT ELECTRIC TRAMWAYS CO.—The directors announce that they do not feel justified in making at the present time any payment on account of the preference dividends.

LA CAPITAL TRACTION & ELECTRIC LIGHTING CO. (BUENOS AYRES).—A dividend of 3⅛ per cent. on the ordinary shares for the 15 months to March 31st, 1908, has been declared.

NATIONAL TELEPHONE CO.—Dividends at the rate of 6 per cent. per annum are recommended on the preferred and deferred stocks. £140,000 is to be placed to reserve, and about £10,000 carried forward.

The transfer books of the company in respect of the preference shares and preferred and deferred stocks, will be closed from the 10th until the 23rd of July inclusive.

OKONITE CO.—An interim dividend of 8s. per annum less income tax on the ordinary shares is recommended for the past quarter.

UNITED ELECTRIC TRAMWAYS OF MONTEVIDEO.—The whole of the outstanding balance of the 5 per cent. debentures has now been sold, completing the authorised issue of £800.000.

WEST KOOTENAY POWER & LIGHT CO.—Applications are being invited by the Bank of Montreal for £240,000 first mortgage 6 per cent. bonds of £100 each at 103.

APPOINTMENTS AND PERSONAL NOTES

Mr. J. H. Thompson, Assistant Engineer, Burton-on-Trent, has been appointed Station Superintendent at Carlisle out of 160 applicants.

Lieutenant F. G. Loring, R.N., has been appointed Inspector of Wireless Telegraphy at the General Post Office.

The Electricity and Tramways Committee of the Warrington Town Council has resolved to appoint Mr. H. B. Jackson Chief Assistant Engineer, at a salary of £150 per annum, in succession to Mr. Purse, resigned. After consideration of the suggested re-arrangement of the duties of the Engineer and Tramways Manager, the committee has decided that the charge of car-sheds, upkeep of cars and the engineering work connected therewith, and the control of the men employed on the work, be transferred to the Tramways Manager without any increase of salary for six months; the salary of the Engineer to remain as at present.—The committee has also decided that Mr. F. V. Jordan be appointed Mains Engineer, at £130 per annum, rising by £10 per annum to a maximum of £150.

Digitized by Google

COMPANIES' MEETINGS AND REPORTS

BUENOS AIRES AND BELGRANO ELECTRIC TRAMWAYS.—An extraordinary general meeting was held last week for the purpose of confirming the resolution passed on June 11th last, with regard to the voluntary winding up of the company. Mr. J. B. Concanon and Mr. H. S. M. Woodrow were appointed liquidators at the remuneration of £750.

GREENWOOD & BATLEY.—At the meeting last Friday, Mr. A. Greenwood, who presided, said that the amount of work turned out had considerably increased, and that although the prices they had been able to obtain were not high, the profits were almost double those of the previous year. In view of the general depression of the engineering industry, it was proposed to pay a moderate dividend and increase the amount carried forward. The directors had decided to call up the balance of the ordinary shares, on which only £3 had been paid up. The report was adopted.

MARCONI INTERNATIONAL MARINE COMMUNICATION CO.—The balance sheet to June 30th, 1907, shows that the issued capital amounts to £204,056, in addition to £20,000 debentures; outstanding debts amount to £20,269, making a total debit of £247,325. On the other side of the account, plant, apparatus, &c., are valued at £13,163, office furniture at £1,093, license and rights £105,115, contract with Lloyd's Corporation £977, shares in Associated Companies £2,375, debtors £4,397, and cash £34, thus showing a balance of expenditure over receipts from the incorporation of the company to date, £98,831.

NEW GENERAL TRACTION.—The twelfth annual general meeting was held last week, Baron E. B. D'Erlanger presiding. An increase of about £4,000 in the receipts from the securities held in subsidiary companies was reported, in addition to a profit of £913 by way of commission on new contracts at Coventry. The chairman said that the company was now practically a trust company, holding securities in the following different undertakings :—The Coventry Electric Tramways Co., Norwich Electric Tramways Co., the Douglas Southern Electric Tramways, and the Philadelphia Street Railway undertaking. Of these the Coventry tramways had been most satisfactory during the last two years, as they not only showed a large increase in receipts, but had yielded a handsome return on the capital invested. The working of the Norwich Electric Tramways was described as very disappointing. The report and accounts were adopted

UNDERGROUND ELECTRIC RAILWAYS COMPANY OF LONDON.—Meetings were held last week of the holders of unpaid coupons for interest in the profit-sharing secured notes of the power-house debentures and power-house second debentures, and in each case the following resolution was passed :—"That this meeting, having considered the scheme of arrangement dated April 7th, 1908, submitted to this meeting, a copy of which scheme has, for the purpose of identification, been signed by the chairman of the meeting, and the draft trust deed between the Underground Electric Railways Company of London (Limited) of the one part, and the London and Westminster Bank (Limited) as trustee of the other part, for securing the three classes of bonds to be issued pursuant to the said scheme, when such scheme has been approved by the Court, a copy of which draft trust deed has for the purpose of identification been signed by the said chairman, hereby approves the said scheme and draft trust deed with such modifications in the said scheme as may be necessary to make the same conform to the said draft trust deed, and with such modifications (if any) in the said scheme and draft trust deed or either of them as the Court may think fit to approve or impose."

A meeting of the holders of the profit sharing secured notes of the Underground Electric Railway Co. of London was held on Tuesday to consider the scheme of arrangement proposed between the company and the creditors. Sir George Gibb, who presided, said that when the scheme had received the approval of the debenture holders, it would at once be submitted to the Courts. He hoped that the temporary liquidation of the company would be ended in a few weeks. The scheme was agreed to.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars net c.i.f. port of arrival quoted on Tuesday night was £59 to £59 10s. per ton (last week £58 15s. to £59 5s. per ton).

CHANGE OF ADDRESS.—Messrs. J. E. Lea, makers of the well-known Lea water-measuring apparatus, have removed from 46 Brown Street, Manchester, to 28 Deansgate, Manchester. The telegraphic address will remain "Recording, Manchester" as before.

ELECTRICAL CONTRACTORS' ASSOCIATION.—Owing to the great strides made by the Electrical Contractors' Association, they have decided to take larger offices at the same address, 20 Bucklersbury. In future the offices will be at No. 282, on the fourth floor, instead of on the lower ground floor. Telegraphic address and telephone number will remain the same.

MESSRS. G. M. BODDY & CO. inform us that, to meet the conveniences of their numerous customers in the south of England and especially in London, they have opened a branch at 15 Gray's Inn Road, W.C. This is situated near the Holborn end of the road. The telephone number is 4814 Holborn. Mr. E. Slade Templeton, M.A., A.M.I.C.E., who is well known in the trade, has been appointed commercial engineer and manager of the branch.

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—At Manchester Bankruptcy Court on Friday last, the public examination took place of Walter Wardle, electrician, of 14 Osborn Road, Levenshulme. The statement of affairs showed a deficiency of £1,097 6s. 3d. on unsecured liabilities £1,117 6s. 3d. In reply to questions, debtor said his failure was due to claims upon him in respect of the debts of a former partnership. In May, 1907, a limited liability company was formed to take over the business, and debtor was appointed manager at £4 a week. Pressure by creditors, however, had resulted in bankruptcy proceedings against the debtor. The company had been worked at a profit.

A petition has been filed re Francis Benjamin Eggington, electrical engineer and contractor, of Wolverhampton. The deficiency is given as £82.

The first meeting in the bankruptcy of T. A. Evans & Co., electrical engineers and contractors, of 14 Heathfield Street, Swansea, will be held to-day at 11 a.m., at the Official Receiver's Offices, 31 Alexandra Road, Swansea, and the public examination will take place at the Town Hall, Swansea, on July 31st, at 11.30 a.m.

Reid's Electrical Co., Ltd., is to be wound up voluntarily. Mr. D. S. Fripp, 90 Cannon Street, London, is liquidator.

The Chipping Norton Electric Light & Power Co., Ltd., is to be wound up voluntarily. Mr. A. Harlow, 8 Maitland Park Road, Haverstock Hill, London, is liquidator.

The Buenos Ayres and Belgrano Electric Tramways Co., Ltd., is to be wound up voluntarily. Mr. J. B. Concanon, 28 Austin Friars, London, E., and Mr. H. S. M. Woodrow, 52 Moorgate Street, London, are liquidators.

Creditors of Messrs. Meldrum Bros., are asked to send in particulars of their claims to T. Gregory, Parr's Bank Buildings, 3 York Street, Manchester, by August 14th. The same announcement is made in respect of the Société Meldrum, Ltd.

Interruption to the Shetland Cable.—A complaint has been received by the Aberdeen Chamber of Commerce that, owing to the breakdown of the telegraphic cable to Shetland, business, and especially the herring business, has suffered considerably. For the last few weeks telegrams have been sent through Kirkwall, involving a delay of from two to four hours in transmission. A letter has been received from the Postmaster-General, stating that the working capacity of the Kirkwall route had been temporarily increased, and that a cable ship was engaged in carrying out repairs to the direct cable to Lerwick.

Telegraph Traffic.—The repairs to cables in the Mediterranean have not yet been effected, and it must be presumed that the breaks are of a more serious nature than was supposed. There are no interruptions to submarine cables to announce, nor restorations to notify. The only disturbance which has taken place is on the lines of the Indo-European Telegraph Co., whose system has suffered interruption between Tauris and Teheran, but it is probable that this is due to the disturbed state of the country where the break has occurred. There may, of course, be other disturbances, but those companies which own duplicate routes are in the habit of keeping them quiet, as the ordinary telegraphic facilities are not thereby impaired or the charges per word altered.

Damage to Cables by Trawlers.—The Postmaster-General, after consultation with the President of the Board of Trade, has appointed a committee to inquire whether the damage done recently to submarine cables in the waters off the south-west coast of Ireland has been caused by the operations of trawlers; and, if so, to consider and report what steps it may be desirable and practicable to take to prevent such injury in future. According to the *Daily Telegraph*, the committee is constituted as follows :—Sir J. C. Lamb, C.B., C.M.G., formerly Second Secretary to the Post Office (Chairman); Mr. W. R. Culley, I.S.O., Submarine Superintendent in the Engineering Department of the Post Office; Commander G. C. Frederick, R.N., professional member of the Harbour Department of the Board of Trade; Mr. C. E. Fryer, I.S.O., Superintending Inspector of English Fisheries; Mr. W. S. Green, C.B., Chief Inspector of Irish Fisheries; and Commander G. M. Marston, of the Hydrographic Department, Admiralty. Mr. F. J. Brown, of the Secretary's Office, General Post Office, will act as secretary, and any applications from persons desiring to offer evidence should be addressed to him. The committee has been requested to report as speedily as possible.

THE THIRTEENTH CONVENTION OF THE INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION

(*Continued from p.* 68.)

THE TESTING AND STANDARDISING DEPARTMENT

(*Continued*).

Regulation of Testing Current and Voltage, &c.—The author considers it an advantage for this to be centralised as much as possible in preference to having switches, resistances, and instruments, &c., scattered about the test rooms.

For the actual control of heavy or main current circuits, rheostat switches connected with wire resistances undoubtedly constitute the most satisfactory arrangement. Water and carbon resistances are by no means so convenient; the former owing to the current fluctuations produced by the evolution of bubbles, &c. (*i.e.*, polarisation), and the latter owing to their high negative temperature coefficient. Wire resistances may be constructed of metal, having an almost negligible temperature coefficient. It should be possible to vary the current by practically infinite steps, and a range of from $\frac{1}{100}$th of an ampere to 1,000 amperes may be obtained with comparatively small resistance frames, if suitably designed. The author prefers resistance frames connected up to the rheostat switches in parallel; that is to say, in such a way that the current is increased by putting resistances into circuit in parallel instead of by cutting resistances out. This serves resistance wire, as all the coils are utilised during the passage of the maximum current. The parallel controllers themselves, as distinguished from the resistance wires, are rather more expensive than the simple series rheostat switches, but are far more reliable in their working, and, moreover, the increased cost is not so great as might be supposed on first consideration, since the fact must not be overlooked that each of the contacts has only to carry a fraction of the full current. A convenient arrangement is to have the rheostats in three groups, as follows:—

One group having 10 approximately 1 amp. Steps.
One group having 10 approximately 10 amp. Steps.
One group having 5 approximately 100 amp. Steps.

These would all be connected in parallel, and also in parallel with them again should be a resistance capable of carrying a maximum current of 1·5 amperes, and having a practically infinite range of variation; about the most convenient resistance of this type is the "Kelvin" drum rheostat, which consists of two cylinders, one with a metal surface, and the other insulated; the cylinders or drums are connected mechanically through spur-gearing to a common pinion. The resistance wire is wound on the outer surface of the drums, and can be transferred from one to the other by rotating them, the proportion of wire on either being varied to any required extent.

Special Alternating-Current Requirements.—Fig. 2 shows an arrangement which has been found to be very convenient for all classes of alternating-current meter and instrument testing. The voltage of the alternator may be varied by almost imperceptible steps, from practically zero up to 450 volts. The fine control rheostat in the alternator field can be used for maintaining the watts in the testing circuit absolutely constant, since by moving it slight variations are produced in both the current and the volt circuits, but not to a sufficient extent to be of any consequence, although quite sufficient to give the necessary adjustment of the watts. The main current circuits are controlled in the same way as in direct-current work, except that the fine control is obtained by a resistance in the primary circuit of the current transformers.

The main current circuits and the volt or shunt circuits are quite distinct, there being no electrical connection between them. The former are fed off the secondary side of step-down transformers, the voltage being about twenty; these transformers are built in two halves, and both the primary and secondary windings may be connected in series or parallel, as shown in the diagram. It is thus possible to utilise them with a large range of alternator volts.

The volt circuit is not connected directly to the alternator, but to the piece of apparatus designated "Phase Shifter" in the diagram. A common method of altering the power factor in alternating-current testing circuits is to make use of choking coils, &c., but this method has the great disadvantages that alteration in power factor also produces changes in the volts and amperes. The "phase shifter" overcomes this difficulty. The amperes and the volts may be set to any required value, and the power factor can then be adjusted to any value from zero to unity, lagging, or leading, without disturbing the current or volt adjustments.

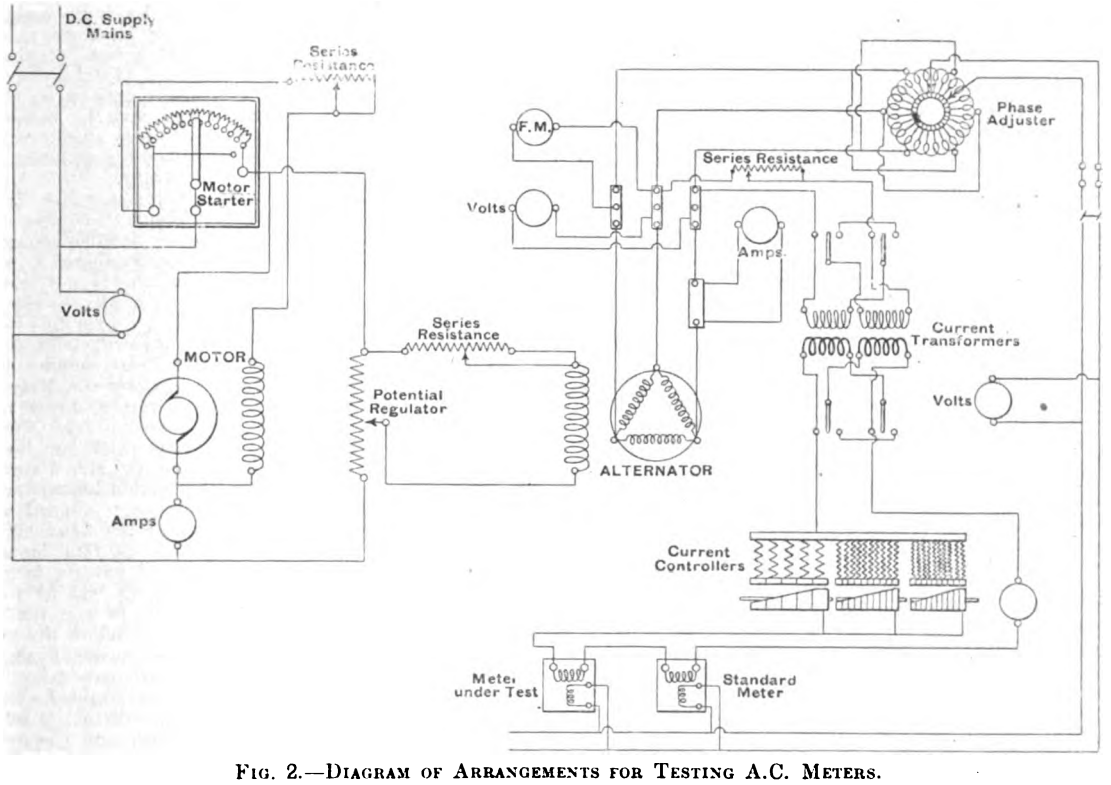

FIG. 2.—DIAGRAM OF ARRANGEMENTS FOR TESTING A.C. METERS.

This principle of utilising a rotating field to produce a difference in phase between two circuits is comparatively old, but there are one or two rather unusual features in the details of construction of the device.

The main portion consists of the armature of a 10 h.p. 400-volt four-pole direct-current motor, complete with windings, commutator, and shaft, &c., the armature being of the toothed core type, with former wound coils. In order to form a closed magnetic circuit, thus avoiding excessive magnetic leakage, and at the same time keeping down the magnetising current, sheet-iron stampings, in the form of annular rings, and separated by paper in the usual way, were pressed over the armature, making good magnetic contact with the iron core stampings. These ring stampings were built up the full depth of the armature, with suitable ventilating ducts at intervals, the whole being clamped between two annular gun-metal end plates by means of four bolts passed through insulated and bushed holes in the plates

Digitized by Google

and stampings. The armature being four-pole, the three-phase mains are led in at six points as shown.

The armature and outer ring are fixed with the armature spindle vertical, inside a specially constructed switchboard, the commutator and shaft end only being visible. A loose sleeve is fitted on the shaft, and on the sleeve two arms are clamped. These arms are provided with wooden handles, and support insulated spindles carrying brush-holders. The brushes are made of copper, and are filed to a knife edge, so that they can only touch one commutator segment at a time, and, moreover, cannot cause a short when moving from segment to segment.

It will thus be seen that by loosening the clamping screws the brushes may be moved relatively to each other, and consequently the voltage between them varied by steps equal to the volts between two adjacent segments of the commutator. When the handles are clamped to the sleeve, the combination as a whole may be moved round the commutator, thus producing any desired phase difference between the "pressure circuit" fed from the phase shifter, and the "current circuit" connected to the L.T. side of the step-down transformers.

Measurement of Current, Volts, and Watts.—The author wishes to emphasise the necessity for definite discrimination between standards and sub-standards. Standard instruments should only be used by the senior testers for the purpose of checking suitable sub-standards; and occasionally in case of dispute they may be used with discretion when conducting any special tests. For direct-current work, the most suitable sub-standards are undoubtedly direct reading instruments of the "moving coil type," provided that well-made instruments are used. Unfortunately, during the last few years the market has been flooded with cheap instruments of this type, which are worse than useless for any but the very roughest class of testing work.

For alternating-current work, "hot wire" instruments form most convenient sub-standards, and possess the great advantage of being unaffected by frequency and external magnetic fields; they may also be checked against the direct-current standards. Wattmeters used as alternating-current sub-standards should preferably be of the dynamometer type, and astatically wound, since this type of instrument may also be checked against the direct-current standards.

The most convenient standards for the checking of current, volt, and watt measuring sub-standards are undoubtedly the "potentiometer" and "Kelvin balances." A most reliable method of measuring alternating-current volts accurately is by means of a sensitive multi-range electrostatic voltmeter. The deflection on the voltmeter when connected to the alternating-current circuit is noted, the instrument is then switched over to a direct-current supply, and the previously noted deflection reproduced by suitable adjustment of the pressure which can at the same time be measured on the potentiometer. This method eliminates all scale and zero errors of the voltmeter.

Wattmeters can, of course, only be checked direct-current with the equivalent of unity power factor; this is not a very serious matter, however, as with well-designed instruments of the type referred to above, the error when working on power factors other than unity is very slight, and, in fact, practically negligible under all ordinary working conditions. The accuracy of a wattmeter on low power factors is naturally of much more relative importance when working "three-phase" than when making "single-phase" measurements; since it is possible for the actual power factor of the instrument circuit to be very much less than the figure representing the power factor of the main circuit. For instance, if the power factor of the system is 0·5, then when making measurements by the usual "two-wattmeter method," the power factor on one wattmeter will be zero, and consequently the instrument should not read at all, and if it should fall below 0·5, then, as is well known, one wattmeter will actually have its readings reversed.

The Price Guard Wire.—The guard wire is a very old, and, unfortunately, rather neglected device for overcoming the difficulties which arise in connection with the measuring of high insulation resistances, owing to the leakage from apparatus and

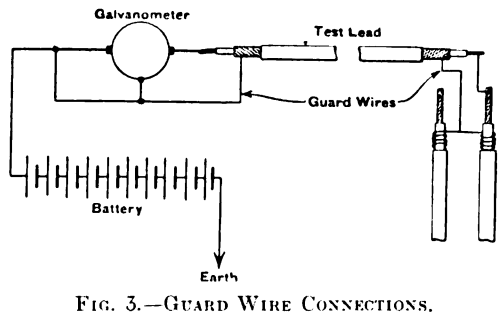

FIG. 3.—GUARD WIRE CONNECTIONS.

test leads, such leakage frequently being greater than the actual leakage through the dielectric of the cable under test. The diagram, Fig. 3, shows a concentric cable used as a test lead, the outer conductor being used as a guard wire. There is thus no necessity for the elaborate paring and drying of the ends. The same applies to the ends of the cable under test, if suitable guard rings are used as shown in the figure. The author has in this way found it possible absolutely to eliminate any leakage deflection on an unshunted galvanometer, having a constant of 1,000,000 megohms when connected to a 400-volt battery, and using a test lead over 100 yards long with damp ends.

Use of Secondary Battery for Mains Testing.—If a secondary battery is installed for the meter and general testing work, there is no reason why it should not be used for insulation testing, &c., provided that a few necessary precautionary measures are adopted. It is necessary to put in series with it a fairly big resistance, in order to guard against short circuit. For insulation testing, one end of the battery will require to be earthed, and it is, therefore, advisable to arrange the circuits in such a way that when the battery is in use for testing purposes, it cannot be connected to the charging circuit, which probably forms a portion of an already earthed network. Banks of lamps are used for the artificial battery resistance, and also act as a potential regulating resistance, thus enabling various intermediate voltages to be obtained.

Chemical Laboratory.—A small room, or a corner of one of the larger test-rooms should certainly be provided with a few of the principal chemical re-agents and a fairly good balance. Such an equipment will be found most useful for testing the purity of mercury, pentane, accumulator acid, bitumen, and box compound, &c., and for various rough tests of a similar nature.

Photometric Work.—The Photometer Room.—This may conveniently be a partitioned-off portion of a larger room. It should be absolutely light-tight, and painted dead black internally, all fittings, &c., being similarly painted. One end of the room should be arranged so that it may be screened off from the main portion, and should also be built higher, in order to accommodate arc lamps, &c., and the dome so formed may also be provided with a horizontal screen or shutter. The vertical and horizontal screens should also be provided with a number of small doors about 8 inches square, so that the rays of light from the lamp under test may be measured at any angle. The atmosphere in such a room soon becomes vitiated and almost unbearable; good light-tight ventilators and a small electric fan will therefore be necessary.

A convenient length for the photometer bar is about 150 inches, and it should for preference have two sets of divisions; one scale being graduated in inches or centimetres and numbered from both ends; and the other scale numbered from the centre to either side, and so graduated as to give the quotient of the square of the two distances of any point on the bar to the lights under observation.

Probably the most convenient standard, both for reliability and durability, is the "Harcourt" 10 candle-power pentane lamp, the authorised standard adopted by the Metropolitan Gas Referees. It is very necessary, therefore, to correct all comparisons made with this standard, for the effect of barometric or hygrometric conditions, which can be easily done by means of the formula established by Mr. Paterson, of the National Physical Laboratory. A reliable barometer and hygrometer will be required for the purpose; a good wet and dry bulb thermometer probably constitutes the most convenient and practicable form of hygrometer. The pentane lamp should be used as a primary standard only, and not for long at a time, and metallic filament lamp sub-standards will be found useful. Before calibration they should, if new, be run for at least "hours, and the volts should be rather below the normal when making the final adjustment of candle-power. Such a calibrated sub-standard will retain a definite candle-power for two or three hours, provided that the current is maintained constant; this should not be done by adjusting the volts at its terminals, but by actually measuring the current taken, on the potentiometer, and regulating it with a resistance having a fine range of adjustment. By this means all errors due to drop of volts in contacts are eliminated. After a set of comparisons with other lamps have been made, the sub-standard should again be checked against the pentane lamp.

There is a considerable difference of opinion as to the best form of "comparison box or photometer head." For comparing lights of different colour, such, for instance, as a mercury vapour lamp and a carbon filament lamp, the author prefers the Simmance Abady Patent Flicker Photometer. For the ordinary work of comparing incandescent lamps with a standard incandescent lamp, excellent results may be obtained with a grease-spot photometer, and also probably with less fatigue to the eyes and in less time than would be possible with the flicker type.

Portable photometers have been brought prominently into notice lately owing to the various discussions, &c., which have arisen on the subject of "street lighting." There is, unfortunately, a good deal of doubt as to what a portable photometer is really intended to measure, one authority contending that it should indicate the intensity of the illumination on a horizontal surface, others consider the vertical illumination should be measured, and one authority that all measurements should be taken on a plane at 45° to the horizontal. The author prefers to use a photometer which, when fixed in any position, can be focussed on any desired light, and permit of measurements being taken of the actual illuminating value of the direct focussed ray from that light in candle feet.

Mains Testing.—A very fair indication of the healthy state or

Digitized by Google

otherwise of a cable after laying can generally be obtained by the use of a compact portable "insulation testing set," such as the "Silvertown" or the "Kelvin." For quick work, and when the insulation resistances to be measured are not very high, instruments of the ohmmeter and generator class give reliable results.

Should it be necessary to measure resistances of the order of several thousand megohms, it will probably be found most convenient and satisfactory to have a small hooded handcart fitted with a 300- to 400-volt battery of small dry cells and a simplified form of laboratory outfit.

The periodical testing of the distributing system under working conditions has been very much neglected in the past, but engineers are now beginning to realise the advantages of being able to feel the pulse of the network.

Many suitable methods for conducting tests of live networks have been described at various times. The "Russell" test is a very convenient one to carry out, and has been reduced to its simplest form in the extremely ingenious instrument known as the "Groves" network tester. The only objection to the Groves instrument is the rather limited range of the scale readings. It has been found very convenient to use a multi-range ammeter and voltmeter for this test, since it then becomes practically possible to obtain open scale reading under almost all conditions.

It is also a great advantage to have the combination of apparatus used for this class of test made up in a portable form, so that it can be carted about to various sections of the network, fed, possibly by separate generating or sub-stations. If suitably designed, such a set may be utilised for a great variety of useful tests. Fig. 4 shows a simple arrangement which has proved itself to be most convenient for the purpose. The four-way ammeter switch gives ranges of 5, 10, and 50 amperes, also a by-pass position. The voltmeter has 75, 150, 300, and 450 volt ranges. Should the outer faults be nearly balanced, an artificial fault of 10, 20, 30, or 40 ohms can be thrown on either side of the system by means of the two-way knife switch.

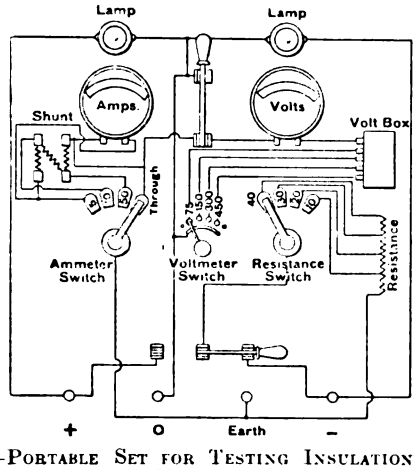

FIG. 4.—PORTABLE SET FOR TESTING INSULATION OF LIVE NETWORKS.

Breakdown tests, when necessary, should, if possible, be conducted from the generating station, the reason for this being that a comparatively large amount of power is required to satisfactorily break down a cable. The most satisfactory arrangement is to have a separate step-up transformer which may be connected to an isolated generator, and the secondary winding to the cable under test; this winding should be sufficiently heavy to carry a current of 5 to 10 amperes, since it is frequently necessary after breaking down a fault to be able to maintain a fairly strong arc in order to produce a permanent short circuit or earth connection suitable for localising purposes.

A portable testing plant is very convenient for carrying out the Board of Trade "double working pressure test" on sections of high-tension feeders before they are joined through to the generating station; or for testing cables which cannot be linked through to the station. In Manchester they have a very complete portable set for making tests of this description, all the necessary machinery and apparatus being installed in a specially-constructed van, which may be drawn by two horses. Briefly, the arrangement is as follows:—A 10-kw. 500-volt single-phase alternator is direct coupled to a 16 B.H.P. direct-current motor. The alternator is connected to the primary of a "Cowan-Still" patent regulating transformer, and the secondary of this transformer is connected to the primaries of three oil insulated and cooled step-up transformers. These three transformers are wound for 500 volts on the primary side, and the secondary winding on each is in five sections of 2,000 volts each. Switches on the tops of the transformers permit of any required number of these sections being connected into the secondary circuits. These switches are, of course, never operated when the transformers are alive. The secondaries of the transformers are connected in series, consequently voltages up to 30,000 may be obtained. The transformation ratio of the regulating transformer may be varied through a practically infinite range from $\frac{500}{0}$ to $\frac{500}{500}$, thus rendering unnecessary the use of regulating resistance in either the motor or alternator field. A small resistance is, however, useful in the motor field for the purpose of maintaining the frequency constant. The direct-current supply for the motors is usually obtained from the nearest point on the low-tension network. Should this not be available, it is generally possible, since all high-tension cables are in duplicate, to utilise one as a low-tension feeder, whilst the other cable is under test.

The chief disadvantages of such an otherwise ideal and convenient set are that the secondary windings of the transformers are wound with a very fine wire, so that it is not safe to take a current much larger than one ampere from them, which is sufficient to indicate a fault, but not to break it down. That it is not possible to test very long lengths of cable, owing to the large capacity currents, which heat the secondary winding. Finally, that owing to the small size of the plant, and the fairly high magnetic leakage in the transformers, it is necessary to exercise great care when raising the pressure on a cable, as the conditions are very favourable for producing resonance effects; and, moreover, the comparatively heavy leading current causes a considerable rise in the terminal P.D. of the transformers and alternator. It has frequently been found that an adjustment of the transformers, &c., which would give a pressure of about 10,000 volts on open circuit, will easily give from 15,000 to 20,000 volts on a long length of cable. When conducting tests of this description, it is therefore essential to have a high-tension voltmeter connected directly to the cable, instead of estimating the pressure from the readings of a voltmeter in the primary circuit of the transformers.

To attempt to describe any particular form or collection of apparatus as being the most suitable for fault localising would probably be a rather dangerous proceeding, as nearly every engineer has his own pet method of carrying out these tests.

It may not be out of place if the author refers to a simple, but little used, method for making a slide wire bridge, used for the loop method, practically direct reading, and at the same time utilising the full length of the slide wire. Fig. 5 is almost self-explanatory. The faulty cable is connected to the terminal *A*, and the loop or return cable to *B*. The other gap

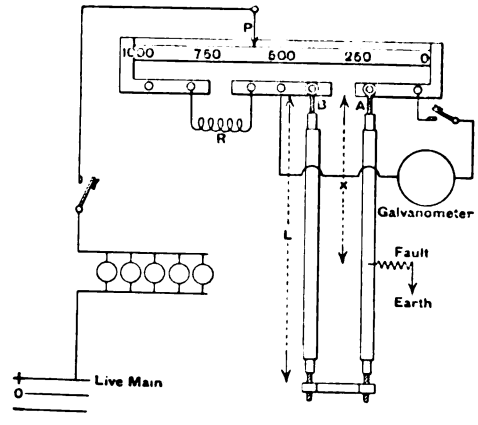

FIG. 5.—MODIFIED FAULT-LOCALISING BRIDGE.

of the bridge is closed by a resistance *R*, exactly equal to the resistance of the slide wire, and preferably constructed of the same size and class of wire. If an ordinary millimetre scale is used, and the full length of 1,000 millimetres is taken to represent unity, smaller readings representing proportionate decimal fractions.

Then if L = length of cable (single), and p = reading on scale, $x = pL$, it will be seen that the available length of scale is exactly doubled, since if the extra resistance was not used, no reading beyond 50 centimetres could be obtained.

Motor Test-room.—These tests are frequently carried out at the manufacturers' works, but the author is rather sceptical as to the reliability of them under these conditions, and prefers to have them conducted in the Corporation's own test-room. Experience has shown the importance of these tests, since about 50 per cent. of the motors delivered require adjustment in some form or other, and it is frequently necessary to reject machines altogether. If the repair work is undertaken by the motor department, as it should be, then, of course, a suitably-equipped test-room is absolutely essential.

It is advisable to make rough efficiency tests on all sample machines, and occasionally on an odd one or two out of a large delivery. Tests made on a large number of motors have shown that in the case of most firms of repute, the actual efficiencies of the machines agree very closely with the maker's guaranteed figures.

The following characteristics of a D.C. motor are the ones which mostly concern the actual users: Speed variation (with

Digitized by Google

varying load); speed-variation (with varying temperature); temperature rise; and sparkless commutation under all conditions of load and temperature. All this information is obtained from, say, a six hours' run at full load, combined with short tests at varying loads, both before and after the six hours' heat run.

The motors are most conveniently loaded by belt connecting them to dynamos, the output of the latter feeding back to the supply. The principle is similar to the Hopkinson test, except that owing to the belt drive, and probably considerable difference in size between the motor and dynamo, it is not possible to obtain reliable figures for the efficiency of the machine on test. Some form of test bed will be necessary to accommodate the various sizes and makes of motors, a very simple and efficient one may be constructed out of two sets of large slide rails, placed one set on top of the other at right angles. The loading dynamos should be permanently fixed and have their field magnets separately excited, it is also an advantage to have two or three different size pulleys to fit the shafts, so that the necessary range of speed when driven by motors of different size and make, may be kept as small as possible. All connections for the tests should be absolutely permanent, the necessary control being centred at a suitably-designed switchboard, from which cables are carried to terminal blocks fixed near the test-bed. In the switchboard described in the Paper, the motors or the dynamos may be connected to either a 200-volt or 400-volt circuit by means of links. The motor is run up to speed, and the excitation of the corresponding dynamo raised until its terminal P.D. is equal to bus-bar pressure; it is then paralleled on to the bars, just as in a generating station; and the load on the motor then adjusted to any required amount by altering the dynamo field excitation. It is not necessary that the dynamo should be feeding back on to the same mains to which the motor is connected; the motor might be on 400 volts, and the dynamo on 200 volts, or *vice versa*.

Ammeters are provided in the motor main circuit, field circuit, and dynamo main circuit. The field ammeter readings enable temperature curves to be drawn.

Motor starters require to be tested for correct coil resistance, adjustment of overload and no-volt release coils, &c., also for heating when starting up a motor under the conditions of the specification or guaranteed time limit rating. For testing the coils, some form of direct-reading ohmmeter is most convenient.

This can easily be constructed in the testing department out of any old moving coil instrument. Advantage may also be taken of the equipment of other sections for the necessary high-pressure flash tests, and drop of potential tests on repaired armature and field coils, &c. An ohmmeter and generator will fulfil all requirements of insulation testing.

Workshops.—Most of the work is bench work, and comparatively light; any job necessitating the use of heavy machine tools should preferably be handed over to the generating station construction and repair shops. The actual work of repairing all motors, starters, meters, instruments, &c., can certainly be executed more expeditiously and cheaply than would be the case if it were undertaken by the makers, but, as a rule, it does not pay to construct the more elaborate spare parts.

In conclusion, the author begs to acknowledge his thanks to Mr. S. L. Pearce, Chief Engineer to the Manchester Corporation Electricity Department, for sanctioning the use of drawings, and the various references to the work and equipment of the Manchester Testing Department. Also to his assistants, Messrs. A. E. Jepson and J. S. Westerdale, for the preparation of most of the drawings and diagrams.

DISCUSSION.

Mr. G. WILKINSON (Chief Electrical Engineer, Harrogate) said that, unless an engineer gave very careful attention to the accurate metering of his current, he was very much like the man who was trying to stop a leakage at the spigot of a beer barrel when all the time there was a much greater leakage at the bunghole. Most of the early testing apparatus was more suitable for telegraph engineers, and even in later years many stations had sprung up in all parts of the country, in which the question of standardising and testing instruments appeared to have been almost entirely neglected. Mr. Ratcliff had suggested a method of dealing with these cases by co-operative working of a testing station. He was entirely opposed to this recommendation, because he thought if there was one place where a testing station ought to be, it was in the centre of the area where the distribution and the central station was situated. He was of the opinion that co-operative working would mean greatly increased costs in the shape of fees for testing, there would be very great difficulties in transporting the large number of apparatus that required attention, whilst many of the smaller individual tests which, when taken singly, were of little importance, and yet collectively were of great value, would be entirely neglected. Also, it would be extremely difficult to carry out routine tests, viz., the systematic bringing in to the test-room of the meters, taking street by street, and examining them in a definite and methodical way. It had been a great surprise to him to find what a substantial increase in the revenue had been obtained by these systematic routine tests. In many instances it was found that meters which had been out for two or three years were running slow, especially on light loads, and were quite incapable of measuring the small currents that might be taken for lighting three or four lamps. Sometimes a meter was running fast and counting against the customer, but for one like that they would find dozens that were running too slowly. In reading through the details of the ground which Mr. Ratcliff thought a testing department should cover, he noticed some times which hardly came within the scope of a testing department. For instance, it was suggested that the instruments should be made there, and also that armatures should be rewound or reconstructed there. He found that for a small station such as that at Harrogate, they had, for a capital expenditure of £250, sufficient instruments for carrying out all the other operations mentioned in the schedule of the Paper, excepting, perhaps, where Mr. Ratcliff mentioned high-tension portable testing apparatus capable of giving a primary pressure of 30,000 volts. But this would only be required in a very large station. Any station, however, that could not afford an expenditure of, say, £500 on testing plant would have very great difficulty indeed in justifying its existence as a supply authority, and ought not to have been set up. There was one very good guide as to the accuracy of meter testing, and that was, when they put in meters, they always had a certificate from the makers as to the accuracy. If they found meters from any one special maker varying from their own findings, then they could easily get a reference to some standardising institution. He had done this on several occasions, and had made arrangements with the makers that whoever was furthest from the correct standard should pay the fees for the reference, and he was pleased to say that in every case the makers had had to pay. Reference was made in the Paper to a very interesting piece of apparatus called a phase shifter. This was evidently a home-made instrument, but he would like to know either from the author or from anyone else if any similar piece of apparatus was on the market, and could be purchased. Another instrument which would be very useful to single-phase stations would be a simple and reliable power-factor indicator. He had made inquiries, but had never found a really good one.

Mr. HAYDN T. HARRISON said the paper particularly interested him, because he had been responsible for the lay-out of some of the big testing stations in this country, including the meter-testing department of the City of London about five or six years ago. The phase-shifting device which Mr. Wilkinson had called attention to was very ingenious, but as to whether it could be purchased he did not know. He knew, however, that it was being used by a number of the best meter-makers. He was inclined to agree with Mr. Wilkinson that it was not always possible to rely upon the phase indicators which were purchaseable at the present time. There was little doubt that for street photometry the best basis of comparison was horizontal illumination, and if they took the measurement on a plane at 45 degrees to the horizontal, it was possible to get through the measurements very much quicker. He had had to carry out 200 measurements in the street in a night, and it made a difference of several hours whether he had to adjust his screen or whether he did not. The author obviously corroborated this view in practice, because he mentioned he used a Simmance-Abady head. This measured at an angle which was never horizontal. He always used to use it himself, but not in the way it was intended, but at a fixed angle, and he corrected the readings afterwards. He warned people against following the author's advice and using a Harcourt standard. He had found more errors in photometry in different testing rooms due to the use of a Harcourt standard than anything else. The best way was to have their own sub-electric standard, to send it to the National Physical Laboratory to be checked.

Mr. A. J. CRIDGE (Assistant Engineer, Sheffield Corporation), on the question of alternating-current supply for testing work, said he had recently had an opportunity of going round a large manufacturing works, and in their testing room they had a special motor generator working in conjunction with a special battery. The phase shifting device mentioned in the Paper had attracted his attention, because a month or two ago he had been struck by the necessity for such an instrument, and he had made one, but had not had time to make tests before coming to the meeting. He had just received a telegram from Mr. Beauchamp, the Chief Assistant Engineer, however, to the effect that they had got 160 volts out of it, and some additional turns were necessary to obtain the requisite pressure. This was due to the fact, he thought, that the air gap was rather large. In making this instrument up he had taken the stator of a four-pole motor, and on each of the four poles there were 600 turns of wire. On a special shaped rotor they wound various numbers of turns and brought them out at different terminals, and by putting two phases to the stator and putting the rotor in different positions, he got a considerable phase-displacement. The author had also mentioned cable testing in the Paper, but this was not generally part of the work of a testing department.

Digitized by Google

Mr. H. D. BURNETT (Chief Electrical Engineer, Barrow-in-Furness) said that he had recently found that a whole batch of meters did not agree with the maker's certificate, and it was found that in starting their watch they got a slight error. Even in some of the most expensive watches this error was as much as a second, which was of considerable importance when, as usually happened, the tests were for a short time, say 20 seconds. Another important matter was dial testing. He recently had five or six meters which were tested on being received, but unfortunately the dial test was omitted, and it was not until some little time afterwards that they received complaints. He investigated the matter, and found the meters in question were 25 per cent. wrong. The gear-wheel had been altered at the maker's works and the tester had forgotten to make the alteration in the constant, and consequently the meters went out inaccurate. The tester who was responsible for this had since left the service of the makers. The best test that could possibly be adopted for distributing mains in a three-wire system was to remove the central wire from earth, and earth one of the outers. Any system should be capable of standing such a test, and if it was made during the night or early morning the risk was not very serious.

Mr. R. HORNBY (Siemens Bros. & Co.), speaking from the manufacturers' point of view, said that most disputes on questions of accuracy arose from either the standard instrument not having been checked recently, or to some watch troubles, as the speaker had mentioned. If, therefore, it was possible to link up the testing laboratories with the Board of Trade, so that some machinery would exist by which the sub-standards would be sent to the testing laboratory nearest the place of use, a considerable step in advance would be made. With regard to Mr. Wilkinson's remark about phase-shifters, there were several on the market which could be bought in the ordinary way. These were rather expensive, but a rough-and-ready device could be made for 25s. or 30s., which was better than the arrangements in a good many test-rooms where arc-lamp coils and temporary devices were used. Power-factor indicators he preferred to call by this name, because he did not know of any device which could really be called a meter in the sense of a practical indicator, but the best method was to use a wattmeter and simply compare the true watts indicated against the volts and amperes as shown on ordinary commercial voltmeters and ammeters, and in this way a very simple and effective test was obtained.

Mr. RATCLIFFE indicated his desire to reply in the Proceedings.

The Proceedings of the Convention then terminated with a hearty vote of thanks to the President.

REPORT ON THE BIRMINGHAM AND MIDLAND TRAMWAYS ACCIDENT

COL. H. A. YORKE'S report on the fatal accident that occurred on February 22th, near Gipsy Lane, Brades Lock, between Tividale and Oldbury, on the tramways belonging to the Birmingham and Midland Tramways Company, has now been issued. The car in question had just entered a loop at a speed stated in the evidence to be about six miles per hour, when the rear of the car was seen to drop. The car then swung round to the right, and after travelling about 50 ft. from the commencement of the loop, it came to a stand across the two tracks, and then fell over on to its left side. Just before the car stopped conductor McCabe appears to have alighted and to have run alongside the near side of the car, apparently with a view of speaking to his driver, and it was while he was passing along the side of the car that it fell over upon him, inflicting fatal injuries.

After the accident the left-hand trailing wheel was found to be broken, and from the marks on the ground it appears that this wheel broke as it was passing through the points. This caused the left-hand trailing corner of the car to drop and the leading end to slew slightly to the right. The result of this was that the right-hand leading wheel took the wrong side of the crossing where the inner rails of the two tracks intersect. The leading end then became derailed, and the car swerved still more to the right until, as already stated, it was right across both tracks, when it turned over.

The accident is attributed to the breaking of the wheel. The wheel was of cast-iron with a steel tyre, the cast-iron centre being similar in design to other centres that have been in use on these tramways since their opening for electric traction. In the centre of each spoke there was what appeared to be a thin iron rod extending from the rim to the hub. The spokes were rather light, and it was probably for this reason that the manufacturers caused the iron rods to be placed in the middle of the spokes during the casting. Col. Yorke is of opinion that when the car entered the loop points and the wheel had to travel on its flanges for a short distance, as is always the case at such points, the spokes gave way, and the wheel collapsed, with the result already described.

Wheels of a heavier type are now being fitted.

ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY

IN the June number of *Electrochemical and Metallurgical Industry*, Frank D. Easterbrooks contributes an article upon the new tank house and copper furnaces of the Raritan Copper Works. The building in which the copper is refined is 149½ ft. wide and 584 ft. long. It is divided into three bays running lengthwise, each bay having two 10-ton motor Whiting cranes, equipped with special devices for dealing with a tank full of anodes or cathodes at one time. There are 1,188 depositing tanks in the building, which are arranged in 108 groups of 11 cells each, two groups of 11 cells being placed together so that the electrolyte can be circulated in cascade form through two tanks. As a very large amount of current is used, very heavy bus-bars are employed, the size adopted being 12·75 sq. in. A heavy glass plate 12 in. square is placed on the top of the concrete piers which support the tanks, and thus insulates them from the ground. Special tanks for rinsing the electrolyte from the cathodes after they have been removed from the depositing tanks are located in the main aisles, as are likewise the tanks for scrubbing the slimes from the scrap anodes, before these are returned to the anode furnaces. Each tank contains 24 anodes and 25 cathodes spaced 4⅜ in. apart The anodes are 28 in. wide by 36 in. long, and the cathodes are 30 in. wide and 37 in. in length, thus giving an active cathode surface of approximately 369·5 sq. ft. With a current of 7,500 amp., this gives a current density of 20 amp. per sq. ft. The tank room is divided up into three circuits running the length of the building, one being in each bay. Each circuit of 396 tanks forms a load for one of the electrolytic generators in the power-house. As mentioned, the main bus-bars have a sectional area of 12·75 sq. in., but the bus-bars at each end of the groups of cells are so proportioned that the amount of copper employed is only sufficient to carry the necessary current. The surface of the bars used to form contacts with the anodes and cathodes are triangular; thus they form a knife-edge contact, which is easier to keep clean than a flat bar. The circulation of the current is lengthwise of the house, that of the electrolyte cross-wise. For the purposes of circulation the tank house is divided into six units of 198 tanks each. The rate of circulation is about four gallons of electrolyte per minute, the solution entering at the bottom and overflowing from the top, except for a small portion of heavier liquid, which is withdrawn from the bottom. In most circulating plant one of the chief difficulties is to get a pump which will withstand the corrosive liquid. Hard lead centrifugal pumps are employed, the chief feature of which is that there are no stuffing boxes or wearing parts in contact with the solution, the shaft bearings being placed above the level of the inflowing solution. It is considered that this pump has solved the problem of circulating hot sulphuric acid solution. The method for preparing the starting cathode sheets is described. They remain in the bath fourteen days, the anodes twenty-eight days, when they are taken out, washed free of slimes, and recast in the anode furnace. The amount of copper in the form of electrodes held in the tanks at any one time is between 11,000,000 and 12,000,000 lbs., and the amount held in the electrolyte about 240,000 lbs. The rest of the article deals with the anode furnaces, wire-bar furnaces, and certain mechanical details.

Electrical Engineering at Cornell University.—We have received the following particulars of proposed alterations in the electrical engineering course at Cornell University: In accordance with the plan which has been followed for several years, more time and attention will be devoted to the theory of the characteristic performance of electrical circuits and machines. To provide this time in part, the mechanical laboratory practice will cease at the middle of the senior year. The complete electrical course will then consist as follows: (1) Two recitations per week, and one laboratory period per week throughout the junior year. (2) Two lectures, two recitations, two three-hour computing periods, and two laboratory periods with one recitation per week throughout the senior year. The instruction in electrical engineering in the junior year is intended to acquaint the students with engineering practice, and to indicate the main divisions of the field. The theoretical elements are reviewed to prepare the way for more thorough work in the senior year. During the senior year the purpose is to lay a theoretical foundation for future practice, by studying the performance of circuits and machines experimentally, and by predicting their performance from their dimensions and physical constants. During the second half of the senior year the students are provided with optional courses of a more practical nature, with a view to showing them how the theory is applied in particular lines of work, such as electric railways, transmission of intelligence, design of electrical machines, and power generation and transmission. The fortieth commencement of Cornell University occurred on Thursday, June 18th. The occasion was celebrated by a very large gathering of Alumni. Ninety-nine students completed the course in electrical engineering, a number somewhat smaller than that of last year, when 107 completed the course.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published July 2nd, 1908

A full list of these was published in our last issue. The following are abstracts of the more important specifications.

Names in brackets indicate communicators of inventions from abroad.

1907 Patents

13,190, **Arc Lamp Electrodes.** H. T. HARRISON & HUGO HIRST. Carbon electrodes of large section, and having circular or annular cores of metallic salts or compounds for increasing the brilliancy of the arc. To ensure regular burning, the cores are slowly rotated as they are fed. By putting the salts in as a core or several cores, a large section, and therefore a long life, can be obtained without increasing the proportion of salts. Six claims, eleven figures.

15,367, **Manufacture of Metal Filaments.** BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). According to this invention, carbon filaments are placed together with oxides of tungsten, such as WO_3 or W_2O_5, in a boat of thorium oxide, which is then heated to a high temperature in a vacuum furnace. The tungsten compounds volatilise and diffuse into the carbon, where they are reduced, and in time the whole of the carbon is replaced by tungsten. The resultant tungsten filament is subjected to the shrinking or sintering action of current passed directly through it in the usual way. Four claims.

18,044, **Single-phase Commutator Motor.** FELTEN & GUILLEAUME LAHMEYERWERKE AKT.-GES. The speed of single-phase shunt commutator motors of the type in which the rotor winding is short-circuited, and an exciting current is supplied to the rotor winding through brushes displaced 90° from the short-circuited brushes, is practically independent of the applied voltage and the excitation on light loads, but is fairly constant for a given frequency of supply. In order to obtain wide variations of speed with such a motor, the rotor winding is not short-circuited, but is supplied with a variable potential. By varying the ratio between the stator and rotor potentials, wide variations in speed can be obtained. One claim, one figure.

20,824, **Oscillograph.** J. T. IRWIN. An electric oscillograph for measuring instantaneous values of potential, current, or power in a circuit. The movement of the mirror is caused by the electrostatic attraction between fixed discs and stretched metal diaphragms. Six claims, ten figures.

28, 29, **Mercury Vapour Lamp.** P. H. THOMAS. To start a mercury vapour lamp, the high resistance at the surface of the negative electrode must be first overcome. According to this invention, an auxiliary positive electrode, normally in contact with the negative electrode, is, on switching on, drawn away either magnetically or mechanically, thus establishing an arc. With the aid of a mercury "shifter" similar to the device described in ELECTRICAL ENGINEERING, Vol. III., p. 916, the circuit is broken suddenly, and the rise in potential, due to the inductance in the circuit, is sufficient, now that the surface resistance of the negative electrode is overcome, to start the discharge between the main electrodes. Three claims, eight figures.

1908 Patent

4,433, **Three-phase Motors on a Single-phase Supply.** SIEMENS-SCHUCKERT-WERKE. A method of starting and running star-connected three-phase motors off a single-phase supply, consists in placing an inductive resistance in series with one phase of the stator winding, and an ohmic resistance in series with another phase, these two phases being connected in parallel between the neutral point of the winding and one of the supply terminals, whilst the third phase is connected in series between the neutral point and the other supply terminal. At starting, however, the last-mentioned phase winding carries the geometrical sum of the currents in the other two phases, and a non-uniform rotary field is produced. To avoid this, the third phase is, according to this invention, divided into two halves, and these halves are conected in parallel, or one half only may be used under certain circumstances. The ampere-turns in the three branches are then more uniform. For running, the two resistances are cut out, and two phases are put in series across the mains. Four claims, one figure.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.

Summaries of the more important of these patents will appear in our next issue.

1906 Patent

12,257, DAVY. Electric arc lamps.

1907 Patents

6,203, FESSENDEN. Electric signalling.

8,445, GRÖNDAL KJELLIN CO. & HARDÉN. Electric furnaces.

8,947, ALLGEMEINE ELEKTRICITÄTS-GES. Incandescence bodies for lighting and heating purposes.

11,541, HATFIELD. Electrically operating apparatus.

13,760, RATHBORNE, FIELDING, & LATHAM. Automatic control of the points of tramways.

13,761, ELECTRIC CONSTRUCTION CO., BUCHANAN, & MCMILLAN. Automatic voltage regulator.

13,911, HALL. Transmission systems of motor-driven vehicles.

14,255, OPPERMANN. Secondary batteries.

14,519, BOULT (*Zorge Safety Railway Equipment Co.*). Signalling apparatus for railways.

15,151, FYNN. Dynamo-electric machines of the neutralised conduction type.

16,053, HATFIELD & LEWIS. Arc lamps.

16,145, BOWIE & PHELPS. Electric apparatus for lighting miners' safety lamps.

16,188, BEVIS & CHAPMAN. Fixing the terminals and contact pieces of electrical fittings.

16,334, SIEMENS BROS. & CO. & GRIMSTON. Printing telegraphs.

16,501, ALLGEMEINE ELEKTRICITÄTS-GES. Controllers.

18,111, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Insulating material.

18,332, ROSLIN DIVRY. Multiple-contact switch.

18,956, RHODES MOTORS, LTD., & FIELDEN. Control of induction motors.

19,190, FOX, FAWCETT, & FAWCETT. High-tension ignition plugs for internal combustion engines.

19,670, MURDOCH & KERSEY. Friction permeameter.

20,465, FITZGIBBON. High-voltage plugs and sockets.

21,584, BURKE. Dynamo-electric machines.

22,502, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Methods of neutralising induction from alternating current systems.

23,831, FELTEN & GUILLEAUME LAHMEYERWERKE AKT.-GES. Machines for installations subject to short circuits.

1908 Patents

58, EISENSTEIN. Variable self or mutual inductance.

67, EISENSTEIN. Aerial for wireless telegraphy.

145, RANSFORD (*Soc. Anon. Montbarbon*). Sparking plugs.

1,159, THOMPSON. Regulating apparatus for alternating current circuits.

3,204, SUTTON & SUTTON. Fire alarms.

4,845, SCHELLER. Apparatus for receiving undamped electric oscillations.

5,030, AITKEN. Telephone instruments.

5,497, REUTHE & AMALGAMATED RADIO-TELEGRAPH CO. Receiving apparatus.

6,101, CHAMBERS. Teaching instrument for wireless telegraph operators.

6,409, PAULI. Incandescent filament lamps.

7,913, PARKER. Railway fog-signalling apparatus.

8,013, SIEMENS BROS. & CO. (*Siemens & Halske Akt.-Ges.*). Transmission of signals.

8,190, Firm of ROBERT BOSCH. Interrupters for electrical ignition.

8,547, RUTHARDT. Field magnets for generators.

9,034, SMITH. Fire and temperature alarms.

9,865, BOON. Switch plate for tramway contact wires.

10,856, COTTON. Electric ignition devices.

Complete Specifications open to Public Inspection before Acceptance.

1908 Patents

8,769, BLUM. Sparking-plug.

12,326. STERN. Regulation of induction motors.

12,487, DUPOY. Distribution apparatus.

12,818, TRIQUET. Primary batteries.

Application for Amendment

Further particulars and instructions as to procedure in opposition to amendment will be found in the Official Journal of the Patent Office of July 1st, 1908.

23,977 of 1907. **Telegraph Apparatus.** SIDNEY BROWN seeks leave to amend this application for letters patent for "improvements in telegraph apparatus" by including J. A. L. DEARLOVE, Electrical Engineer, of 4 Great Winchester Street, London, as an applicant for a patent.

Expiring Patents

No patents of electrical interest expired during the current week.

SUMMARY

A letter from Mr. C. McArthur Butler, Secretary of the Incorporated Municipal Electrical Association, refers to the proposal to form a separate section of the Association for Assistant Engineers, and gives particulars of previous attempts in this direction, which did not meet with very ready response. A letter on the subject is also contributed by an assistant engineer. (Page 90.)

A letter has been sent out by the Committee of the Manchester Electrical Exhibition stating that in order to have things quite ready for the opening day, exhibitors will be afforded facilities for erecting their exhibits on and after September 1st, instead of September 14th, as originally arranged. Attention is also drawn to the fact that cases have come to the notice of the Committee of firms who hope to obtain advertisement out of the exhibition by lending machinery or apparatus to exhibitors. The Committee, therefore, ask for the support of the exhibitors in enforcing the rule which prohibits the display of any other name than that of the owner of the stand. (Page 90.)

An article describes recent developments in the electrical department of Messrs. Sir W. G. Armstrong, Whitworth & Co.'s Elswick works. Power for works driving is obtained from the Newcastle-upon-Tyne Electric Supply Co., and the Newcastle & District Electric Lighting Co., and a large amount of electrical machinery and apparatus is manufactured at the works. (Page 91.)

The Mining Exhibition, opened last Saturday at Olympia, contains a number of exhibits relating to the application of electricity in mining, although it can hardly be called representative of that branch of the electrical industry. Several firms show motors and starters specially constructed for mining work, and seven or eight different types of electric coal cutters are exhibited. Some new forms of electrically driven conveyors for underground and surface purposes are shown, and the applications of electric driving to ventilation and pumping are well represented. An interesting exhibit is the Temple electric air drill, which combines the advantages of electric transmission with those of the ordinary compressed air percussion drill. A number of types of electric miners' lamps are on view, some actuated by primary batteries and others by accumulators. The application of electricity to the re-lighting of the ordinary safety lamp underground is exemplified, and there are a number of other miscellaneous exhibits relating to applications of electricity in mines. (Page 93.)

The Tramways and Light Railways Association held its first of an annual series of Congresses at the Franco-British Exhibition on Thursday and Friday. The Duke of Argyll, President of the Association,

Digitized by Google

welcomed the members, and presided over the first part of the proceedings, which consisted of a lecture (largely historical) by Sir CLIFTON ROBINSON. A Paper by Mr. A. H. GIBBINGS on rail joints was then discussed. The Paper included a useful collection of drawings of joints and anchors, and a new adjustable joint support, devised by Mr. Bullough, in which it is understood Mr. Gibbings is interested, formed the subject of some criticism. The discussion also turned on experience with Thermit joints, and on the various causes of joint troubles. A new "mechanically locked" joint which presents some features of interest was exhibited. On Friday morning the proceedings were opened by Mr. A. L. C. FELL, who gave an address on the work of the Association. This was followed by a lecture on "Rail Corrugation," by Prof. CARUS-WILSON. The lecturer confined his remarks to the results of some experiments made on a model, and also on a car at Croydon, and to his own conclusions as to the causes of corrugation. He considers that corrugation is due primarily to the wheels running on unequal diameters, this causing skidding of the smaller wheel. This skidding, if grit is present on the rail, becomes intermittent, the period between the skids depending on the limiting twist of the axle. The lecturer suggested no remedy. A short discussion followed the lecture, and it will be further discussed at a future meeting of the Association. (Page 99.)

THE students of the Institution of Electrical Engineers have just concluded a visit to the Newcastle-upon-Tyne district, when a number of manufacturing works and electrical installations, including an electrically equipped colliery, were visited. (Page 108.)

THE electrical equipment of Horden Colliery is an example of a self-contained continuous-current colliery power installation of moderate size, of which there are a number in the Newcastle district. The generating station also supplies current for lighting the village. Electrical power is used for the screening plant, &c., ventilation, haulage, pumping, and other purposes, but not for main shaft winding. (Page 109.)

Mr. A. M. TAYLOR has sent in some observations in reply to the discussion on his Paper on "The Use of Accumulators for Peak Loads," at the Incorporated Municipal Electrical Association's meeting at Nottingham, and reported in our last issue. (Page 110.)

UNDER "ELECTRICAL SCIENCE," in the British and American Section, is a note on certain obscure points in the electrolysis of water vapour. In the Continental Section, a Paper by JEAN BECQUEREL, in which he announces that he has proved the separate existence of positive electrons in a vacuum tube, is abstracted. (Page 110.)

Mr. A. P. TROTTER has issued a lengthy report on the fire which occurred on the Liverpool & Southport Railway. Some interesting detail is gone into regarding the best methods of wiring the coaches in electric trains, and the practice on the Lancashire and Yorkshire Railway in this respect is compared with that on the North Eastern and London Underground Railways. Although no one was injured, the fire was serious while it lasted, as a powerful arc carrying some 9,000 amperes was maintained for two or three minutes. The direct cause of the short circuit is uncertain, but probably was due to penetration of water during driving rain. The question of modification of the arrangement of the sections and circuit breakers to ensure in a more complete manner the limitation of the current in each section to a value with a reasonable margin in excess of the maximum requirements of that section is dealt with, and it is recommended that the section should be, where possible, of such a size that one train only is likely to start on each. (Page 111.)

Sir OLIVER LODGE has sent us an account of the experiments on the effect of electricity upon growing crops, carried out on an industrial scale by Mr. J. E. NEWMAN, in conjunction with Mr. R. BOMFORD and Mr. LIONEL LODGE. Wires charged positively to a high potential are suspended over the fields, and a sytematic method of observation has shown a distinct increase in both the quantity and quality of the crops obtained. In the case of wheat the increase is in the order of 30 per cent. in the number of bushels per acre. (Page 112.)

SOME particulars are given of the new tungsten lamp which the British Thomson-Houston Company are manufacturing at Rugby. (Page 114.)

A FORM of controller for large motors, which presents some novel features, has recently been introduced. (Page 115.)

A Patent Specification by the GRÖNDAL KJELLIN CO. and J. HÄRDÉN, relating to renewable linings for the fusion chambers of electric induction furnaces, was published on Thursday last. Among the other specifications published was one describing a process for the manufacture of metal filaments by the ALLGEMEINE ELEKTRICITÄTS GESELLSCHAFT, and another by J. BURKE relating to the design of continuous-current three-wire generators. THE BRITISH THOMSON-HOUSTON have one for a method of neutralising inductive disturbances in telegraph and telephone circuits adjacent to rails used as return conductor in alternating-current railway systems. A voltage regulator for use on alternating-current circuits is described in a specification by W. H. THOMPSON, and a specification by C. PAULI relates to the suspension of metal filaments. A Patent granted to E. TYER for a system of signalling on a single-line railway expires during the current week. (Page 117.)

AN action was brought last week against the Llandudno District Council for permitting a nuisance by allowing black smoke to be discharged from the generating station chimney, and the Bench made an order for the abatement of the nuisance.—At the Manchester Assizes on Monday the Corporation agreed to pay £125 damages in respect of the death of a pawnbroker who, it was claimed, died from the after-effects of inhaling fumes arising from the fusing of cable belonging to the Corporation.—After meeting expenditure and capital charges the accounts of the Sunderland Electricity Department for the year to March 31st, show a debit balance of £1,908.—A proposal has been made to utilise the arc lamp posts in Worcester for supporting advertisement signs lit by electricity.—Sir Clifton Robinson has informed the Richmond Town Council that unless the overhead trolley system is agreed to for the proposed trams over Kew Bridge, the Bill now before Parliament will be dropped.—The accounts of the Nottingham Corporation Tramways for the past year allow of £17,000 being contributed to the rates, and the allocation of £4,457 to reserve fund.—There has been a profit of £1,723 upon the Oldham Corporation Electricity Department for the past year. At one time the undertaking had a reserve fund of £10,000, but owing to the Local Government Board refusing to pass certain accounts out of revenue, this had entirely disappeared. (Pages 119 to 122.)

SPECIFICATIONS are in preparation for a new storage battery at the Sydney Electricity Works. It is estimated that an expenditure of £32,345 will have to be incurred in new telegraph and telephone works in Australia during the year 1908-9. Extensions to the Bo'ness Electricity Works are contemplated at an estimated expenditure of £6,000. Local Government Board inquiries are to be held at Eccles (£16,270), Fareham (£10,000), Farnworth (£7,000), and Heywood (£16,000). For the information of wiring contractors we give particulars of a large number of buildings about to be erected in London and the provinces. The Stepney Council is purchasing 73 "Gilbert" magazine flame arc lamps. (Pages 122 to 124.)

Digitized by Google

THE half-yearly report of the National Telephone Co. to June 30th shows income of £1,452,286, an increase of £137,787 over the corresponding period of 1907. The net result for the half-year, after deducting £139,546 Post Office royalties, is a profit balance of £480,641, an increase of £40,661 over the June half-year of 1907. £140,000 are transferred to the reserve fund, which now stands at £2,804,961; 6 per cent. dividends are recommended on the first and second preference shares, on the preferred stock and deferred stock, and 5 per cent. on the third preference shares. The report of the Electric Construction Co. for the year ended May 31st, 1908, shows a net profit, after deducting debenture interest and adding £25,000 to depreciation account, of £5,932. After paying the dividends upon the preference shares for the year to May 31st, 1907, there is a balance to be carried forward of £1,746. There is a profit of £4,860 shown by the accounts of the Electrical Power Storage Co., for the year ended May 31st, 1908. A 5 per cent. dividend upon the ordinary shares is recommended, leaving £369 to be carried forward. Messrs. Thomas Parker & Co., Ltd., has gone into voluntary liquidation for the purpose of reconstruction; a new company is to be formed, with the title of the Rees-Roturbo Manufacturing Company. (Page 124.)

THE Exhibition now being held at Olympia will naturally turn the thoughts of many engineers in the direction of the applications of electricity in mining, and a little inquiry will show that, although electrical mining engineering has perhaps not made its initial strides as rapidly here as on the Continent, a great deal more has been done in this direction in the English and Welsh mines than is generally realised. The formulation of the Home Office rules undoubtedly gave considerable impetus to the adoption of electrical working in mines, and the most formidable obstacle, the innate conservatism of the British colliery owner, has largely been surmounted. Electrical engineers in their enthusiasm are perhaps a little too prone to regard their precious "juice" as a panacea for use under all conditions, but the matter has been thoroughly sifted in the light of solid experience, and there are many purposes for which the benefits of electrical working are universally acknowledged. Electrical underground haulage presents undisputed advantages in flexibility and economy, and there are possibilities in electric pumping unattainable by other means. Electric power is extensively adopted in screening plants and other surface works, and is fast replacing other forms of power for driving ventilating fans. There is less unanimity of opinion regarding mainshaft winding, but in spite of its critics, heavy electric winders with their unique methods of load equalisation are being installed, if they are not already in some cases at work, in quite a large number of British collieries, especially of the South Wales group. Electrical coal cutting has been another vexed question, but its possibilities, as well as its limitations, are now well understood; here, again, the rapid increase of its adoption, where the quality of coal is suitable, speaks for itself.

MR. GIBBINGS' Paper on tramway rail joints dealt with a vexed and vexing question of which the satisfactory solution is yet to be found, or it should perhaps be said that the solution must be fitted to the surroundings, and herein lies the crux of the difficulty. If one had to build a tramway track for its own traffic alone, there is no reason why railway practice in regard to substructure and joints should not give equally satisfactory results. But the requirement that the rail tables are to be laid and kept level with the paving of the road introduces the double difficulty that the rails cannot be packed, or the joints inspected and tightened, without pulling up some of the paving, whilst relative wear or movement between rail and paving surface soon produces nuisance and even danger. The usual British practice of laying rails and paving alike upon a deep concrete bed would meet the conditions fairly well if the rails took and kept a uniform bearing upon the concrete. This can be assured as the original condition by reasonably careful work, but the passage of every car produces some movement which is accentuated at the joints. The many attempts of inventors to make joints which shall not move under the wheel are illustrated by the examples described in Mr. GIBBINGS' Paper. The majority of these are mechanical devices intended to stiffen the joint vertically, and in most cases simultaneously to anchor it into the concrete; but experience shows that such constructions do but put off the evil day. The main reason is that rail joints cannot be fitted with the accuracy necessary to ensure every member taking its proper share of the stresses and shocks incidental to the rolling loads. The theoretical condition is to have a rail so rigid in relation to the loads that the movement of the table shall be only that due to compression, and that such rigidity and movement shall be equal at all points. Unless such equality obtains, the rail is certain to spring with disastrous results to either (or both) the concrete below and the paving around it. The various welding processes aim at producing a continuous rail, but it is doubtful whether the necessity of making the joint neither more nor less rigid than the body of the rail has been sufficiently studied, and herein lies room for improvement. Experience with welded joints has not been uniformly satisfactory, but there seems good reason to interpret the success of the Thermit joint at Leeds, and the Falk joint at Norwich, as testified to by Mr. HAMILTON and Mr. BANISTER in the discussion on Mr. GIBBINGS' Paper, as proofs that, with proper care, work can be done which will stand the test of years of heavy traffic. Unfortunately, the cost of joint maintenance is very hard to get at, and there are great difficulties in comparing experiences owing to the wide variation in local circumstances. All tramway managers are agreed that track maintenance is far too costly now, but experiment is tedious, and they are not so willing to test new devices as would be the case if a few months' trials would give conclusive results.

THE interest which Sir OLIVER LODGE has taken in the experiments made by Mr. J. E. NEWMAN to ascertain whether the stimulation of plant growth by electricity has a real industrial value has been fully justified. By extending over a wheat field lines of wires charged with positive electricity at a high potential, the productivity has been increased by some 30 per cent., and promising results have also been obtained with other crops. Experiments on these lines made by LEMSTRÖM several years ago gave indications of similar improvements, and the present trials must be regarded as the outcome of the work of this pioneer.

Digitized by Google

While, however, LEMSTRÖM charged his network of overhead wires with a Wimshurst machine, Mr. NEWMAN has been enabled to generate the high electrical pressure in a far more reliable manner with a dynamo, induction coil, and Lodge mercury vapour rectifier. The employment of the high-tension rectifier or "valve" at once disposes of all difficulties with regard to the mechanical part of the problem, for it appears that less than 1 kw. has proved sufficient for between 10 and 20 acres of land under cultivation —probably the same machine would have been large enough to keep a far larger network charged. Moreover, the D.C. machine, induction coil, and contact breaker could be replaced by an alternator and static transformer, which would further simplify the apparatus. As the maintenance of the posts, wires, and insulators can only be a trifling annual item of cost, it appears that the method has actually approached the commercial stage of development, although the phenomenon has as yet received no satisfactorily definite scientific explanation. Mr. NEWMAN, who has been working steadily at the subject for five years or more, is to be congratulated on his results.

MANCHESTER ELECTRICAL EXHIBITION

THE following official notices have been issued :—

Erection of Exhibits.—In order to insure that the exhibition will be thoroughly ready and completed on the opening day, October 3rd, the Committee of the Manchester Electrical Exhibition have arranged that those exhibitors having heavy plant to instal or being desirous of obtaining access to the buildings prior to September 14th, the date originally fixed for commencing work, shall have facilities given them for erecting their exhibits on and after September 1st.

Address.—The address of the exhibition is "The Electrical Exhibition, Platt Fields, Rusholme, Manchester."

Foundations.—The committee have made arrangements with the builders on the site, Messrs. J. Davenport, Sons & Co., to put in foundations for exhibitors, who are recommended to make arrangements with them on this matter at once, so that the flooring of the main building can be proceeded with.

Stand Fittings.—For the convenience of exhibitors, Messrs. Barrett & Sons, of 126 Broad-street, Pendleton, Manchester, and Messrs. J. Davenport, Sons & Co., builders on the site, have been appointed official stand fitters to the exhibition, although exhibitors are perfectly at liberty to make whatever arrangements they think fit. In fitting up their stand space, exhibitors must comply with the requirements of the local authorities and fire offices interested in the exhibition, and generally comply with the following conditions :—All stand partitions, counters, &c., shall be specially erected and constructed of wood not less than one inch thick. All material used for covering same shall be of a non-inflammable character or treated with a fire-proof composition. Stalls, staging, counters, or fittings erected by the exhibitors shall not, unless by special arrangement, exceed 14 ft. in height. No exhibitor shall be allowed to display his exhibit in such a manner as to obstruct the light or impede the uninterrupted view along the gangways, project over same, or affect the display of neighbouring exhibitors.

Electricity Supply.—Exhibitors are asked to intimate before July 25th what their requirements are in this respect. As already announced, the price is 2d. per unit for lighting and 1d. per unit for power.

Gas.—Arrangements have been made with the Manchester Corporation for the supply of town gas at a charge of 2s. 6d. per 1,000 ft. for ordinary use and 2s. for gas engines.

Water.—A supply of water at 2s. per 1,000 gallons if metered or, if only a nominal quantity is required, at a price to be agreed.

In both cases the exhibitor must make arrangements with the builder for connecting with the nearest supply mains.

Lent Machinery and Apparatus.—As a number of cases have recently been brought to the notice of the management, of firms who hope to obtain advertisement out of the exhibition by lending machinery or apparatus to exhibitors, the committee have passed a resolution authorising the management to draw exhibitors' attention to this fact, as advertisements thus obtained will obviously be most unfair to those who are supporting the exhibition, and are contrary to the rule which prohibits the subletting of space without the consent of the management, and also prohibits the display of any other name than that of the owner of the stand.

CORRESPONDENCE

ASSISTANT ENGINEERS AND THE I.M.E.A.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—Your correspondents, "J. W. B." and "Chief Assistant," are probably not aware that the suggestions made in your issue of July 2nd, to which they refer, have already had consideration. For some years past my Council have given a great deal of time and attention to the problem of how to cater for assistant engineers.

Three years ago a circular was sent from the Association, together with a form of return, to over 800 assistant engineers in municipal electrical works, suggesting that a separate Convention should be held, or alternatively, that shorter periodical meetings should be organised for assistants in various parts of the country, and asking for expressions of opinion with a view of ascertaining approximately what support could be relied upon, before going further into the matter. Only thirty out of these hundreds took the trouble to reply, so that it was impossible to proceed.

My Council then reduced the Associate's annual subscription from 10s. 6d. to 5s., thinking that a nominal contribution, which includes a copy of the "Proceedings," might be some inducement. This was followed by the offer of a £10 Travelling Studentship for the best Paper on some approved subject, which only attracted one entry in two years. It is not that the Association does not endeavour to meet the wishes of the assistant engineers, but the latter are, apparently, too apathetic to co-operate. If we had the support of the assistants in anything like the proportion we have that of their chiefs, possibly some scheme might be evolved on the lines indicated, and I hope that one practical result of this correspondence will be that I shall receive many applications for admission to the Association, as well as such suggestions for its development, as will appeal more forcibly to the assistant than the efforts which have already been made in that direction have done.

Yours faithfully,

C. MCARTHUR BUTLER,

(Secretary of the Incorporated Municipal Electrical Association.)

Staple Inn Buildings (South),

Holborn, London, W.C.,

July 13th, 1908.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—With reference to your editorial note in ELECTRICAL ENGINEERING for the 2nd inst., re the I.M.E.A. Conventions and the Assistant Electrical Engineer, while I certainly think that it would be to the advantage of both the Association and the Assistant Engineer for the latter to attend the Conventions, the solution of the difficulty, to my mind, rests entirely with our superiors, many of whom are members. I should, however, like to point out that just at the time of the year when the Convention is held, many things need attention in the station, *e.g.*, overhauling, periodical extensions, holiday arrangements, &c., which generally keep the assistant busy, and in many cases prevent him from attending.

With regard to the suggestion that meetings of associates should be held three or four times a year, I certainly think this an excellent idea, and should like to see it carried into effect.

Yours faithfully,

"SUPER."

THE ELECTRICAL DEPARTMENT OF SIR W. G. ARMSTRONG, WHITWORTH AND CO.'S ELSWICK WORKS

ABOUT eighteen months ago we published an article dealing with the electrical driving of Messrs. Sir W. G. Armstrong, Whitworth & Co.'s Elswick Works, and the electrical department of that great establishment generally (ELECTRICAL ENGINEERING, Vol. I., page 155). The recent visit of the students of the Institution of Electrical Engineers to Newcastle gave us, however, another opportunity of inspecting these works, and even in such a short period in the life of a firm notable extensions and improvements have been effected.

The policy of purchasing all electrical power from outside electricity generating companies has so far been adhered to, and a supply is now being taken both for lighting and power from the Newcastle-upon-Tyne Electric Supply Co., Ltd., and the Newcastle & District Electric Lighting Co., both of which companies have sub-stations erected at suitable positions in the area of supply. Three-phase current is adopted for driving shafting and for constant speed requirements, while a three-wire 480-volt system is provided for variable speed motors and lighting. In each of the four D.C. sub-stations balancers sufficiently large to deal with out of balance loads are installed in duplicate. These loads are sometimes considerable, owing to the action of electrically-driven cranes and other intermittent demands. Each sub-station has, under normal conditions, one balancer set running. Should the out-of-balance load exceed 200 amperes for more than 10 minutes another balancer has to be run up. Such a standing rule is necessary to ensure satisfactory balancing.

The low tension sub-stations have now been connected to a central exchange board located approximately at the centre of the works, whereby any shop or group of shops may be connected to and run from any desired sub-station, and balancing may be done from any sub-station. The low tension net work is run solidly so far as balancers and main cables are concerned, fuses being omitted. Owing to the considerable drop which occurred on the low tension system, two double boosters have been built by the electrical department—one of 200 and the other of 300 kw. capacity, and capable of giving 50 volts boosting effect on each side. These have been installed at the power station of the Newcastle & District Electric Lighting Co., Ltd.

In addition to the three-phase and low tension direct-current systems above-mentioned, a comparatively small supply of single-phase current at 1,000 volts is taken from the Newcastle & District Co., and transformed down to 100 volts for purposes of temporary lighting of ships whilst alongside the ordnance works. The temporary wiring and lamps on board these boats as they come from the shipbuilding department happens to be 100 volts, so that this value is adhered to for this purpose in the electrical department. The total horse-power now taken electrically by the firm amounts to 7,822, absorbed by 576 motors, 573 arc lamps, and nearly 3,000 glow lamps.

Probably the most interesting feature at the present time is the lines upon which the electrical department has progressed with regard to the manufacture of electrical goods for the Admiralty and other good class customers. It should be said that to expect cheapness with concomitant nastiness from the electrical department of Messrs. Armstrong, Whitworth & Co. is futile. Their standard designs of motors and other gear, and the precise jig and gauge systems conform rigidly to an exacting Admiralty specification, and it would not pay the firm to manufacture any other grade of production, inasmuch as, besides Admiralty work, its shops are kept full of work for foreign Governments who imitate as closely as possible the requirements of our own. At the time of our visit the engineering strike was in full swing, but nobody would have thought that there was a loss of activity when looking round the electrical shops. At the present time there are over 350 motors and dynamos under construction—operations on some being rather impeded owing to the strike, but nevertheless work is progressing. Among the most interesting specimens are 12 dynamos, each of 132 kw. capacity, destined for two new Brazilian battleships, one of which is

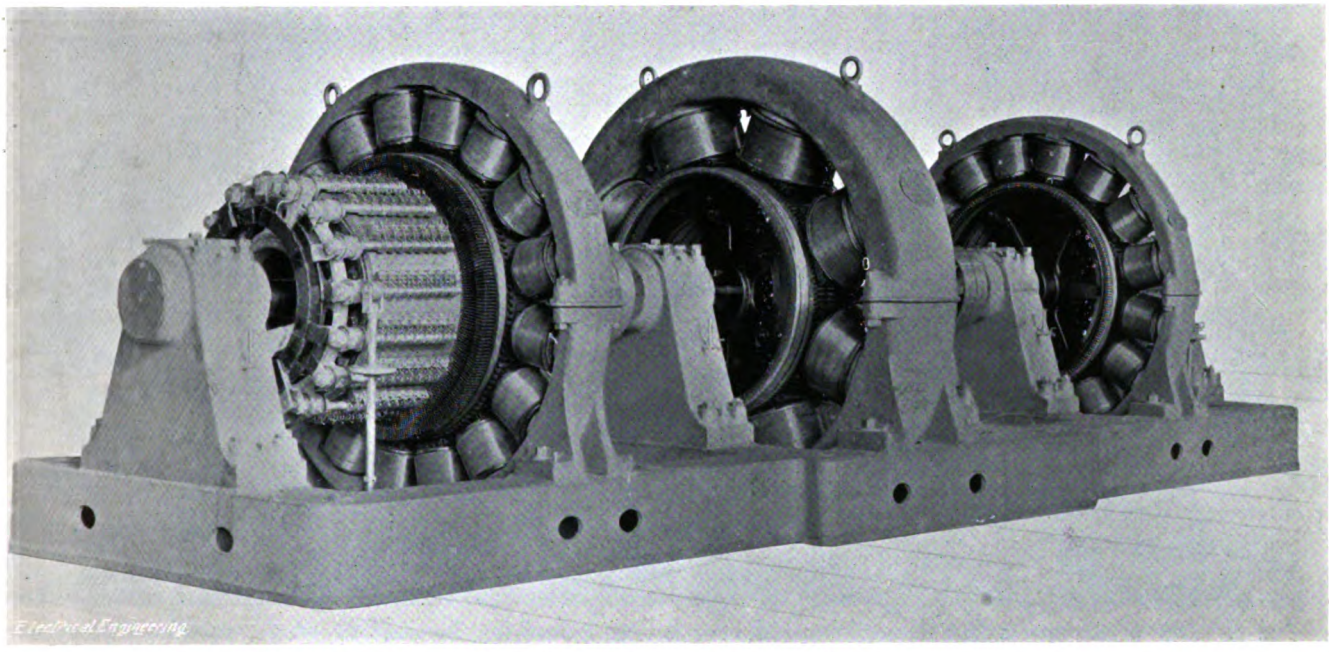

FIG. 1.—LARGE MOTOR GENERATOR SET.

Digitized by Google

being built by Messrs. Armstrong Whitworth and the other at Barrow-in-Furness. Two big double boosters, one of which is shown in Fig. 1, have just been completed. The department is also turning out a line of combined engines and dynamos, the smallest size of which—8 kw.—is suitable for tramp steamer lighting, while the largest standard has a capacity of 70 kw. Above that size the engines are made in the "engine works" department, while the dynamos are, of course, under the hands of the electrical department. This department also maintains the telephone oufit of the firm, amounting to 100 to 150 stations, and the fire alarm system. Fig. 2 gives a general view of one of the electrical shops as arranged on the occasion of the recent visit of the Prince and Princess of Wales, showing examples of electrical machinery recently constructed.

In addition to the work under cover of the shops, the wiring of several large ships is going forward, such boats as the *Lord Nelson*, the *Invincible*, the *Superb*, the *Afridi*, and several foreign ships are at present passing through the final stages, while wiring work is just being started on the new Brazilian battleship of 19,000 tons. Some most interesting work has recently been done by this department in connection with the British Government's new "electrical" ship, the *Invincible*. This boat is the first battleship whose turrets are operated electrically.

The electrical department of this firm is almost limitless in its activities. It appears to make everything electrical, from wireless telegraphy plant—a recent and powerful equipment having recently been established near the mouth of the Tyne—to sparking coils for motor-cars. An interesting example is the electric firing gear for ships guns, which is capable, by means of electric connections, of training the guns by the simple movement of the firing pistol. The cables for dynamo "firing" are armoured with phosphor bronze wire for the upper decks, and lead-covered for the lower-deck service.

The equipment of the works for this class of production cannot be without interest. It would probably be noticed by any visitor that the shops are of a somewhat light construction for large dynamo building, and that the range of heavy tools is not very large. The reason for this is that all heavy engineering necessary is at present done by the adjacent engineering shops, the work being charged against the electrical department. This procedure should be a hint to electrical firms who are not of exceedingly great magnitude to avail themselves more extensively of finished magnet parts and other heavy work offered by general engineers, specialising on the electrical work necessary instead of attempting to do big work with small tools. As an example of the size of lathes used, the most recent addition is an "Openshaw" lathe (from the Manchester works of Messrs. Armstrong Whitworth), with an 8 ft. bed and 14 in. from centre to bed, convertible to a gap lathe if chucking is necessary. The chief feature about all the lathes is their rigid construction, making them adaptable for taking heavy cuts at high speeds. The tool steel used is the firm's own "T.Y.R." brand, which appears to be as great an improvement on Mushet steel as that was on ordinary tool steel. Another point of interest is the heavy percentage which the capstan lathes bear to the total equipment—a rather unusual feature in a shop where such exactingly accurate work is required. It should be noted in this connection that every detail part, whether subjected to one operation or twenty, is carefully checked and passed before being submitted to succeeding operations. As an instance of the speed of production obtained, a brass rod about $\frac{5}{8}$ in. diameter was turned, faced, bored, tapped internally, knurled externally, and parted off in a capstan lathe in nine minutes.

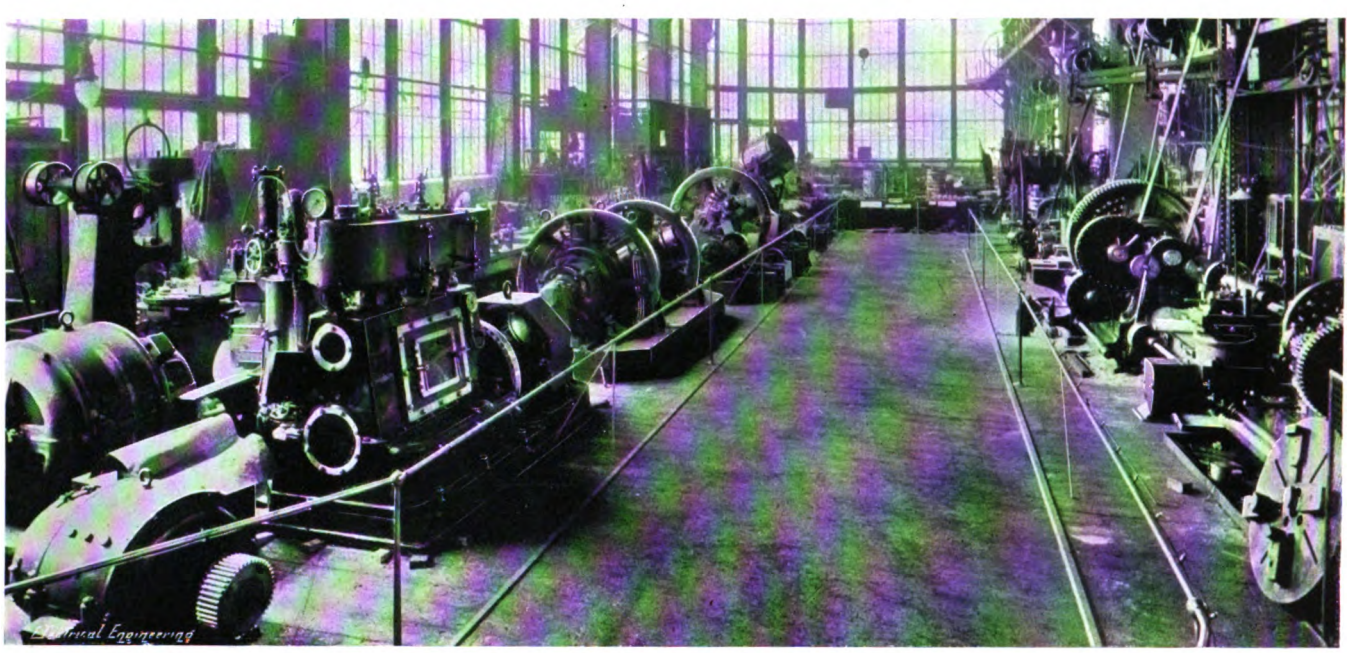

FIG. 2.—VIEW OF ELECTRICAL SHOP AS ARRANGED FOR VISIT OF THE PRINCE AND PRINCESS OF WALES, SHOWING SPECIMENS OF VARIOUS TYPES OF PLANT MANUFACTURED.

The commutator building room illustrates the exactness of production. The wedge-shaped pieces are first ground to a thousandth and tested by gauges, then assembled with gauged mica insulation in such a thorough manner that on our visit a commutator was hammered vigorously for our edification without the slightest signs of starting. Armature and field coils are wound on special machines, and taped by hand, as this gives a tighter binding than that obtained on machines. To fulfil Admiralty specifications they are then armoured with micanite, taped again, and impregnated with varnish in a vacuum-impregnator. One is not surprised to hear that the firm regard the prolonged immersion of these coils in water with equanimity. A further example of their thoroughness is shown in the fact that in squirrel-cage rotors reliance is not placed on sweating. Each rotor bar

Digitized by Google

is double-rivetted to the short circuiting band. Again realising that pole tips require less iron than the central portion of a magnet, the laminated stampings are made with a longer projection at one end than the other, and every alternative stamping reversed so as to leave a polar projection on each side alternatively. It is in minor points of this description that excellence of design is obtained.

The whole of the apparatus turned out is tested for a quarter of an hour for insulation at 2,000 volts alternating. Motors are tested either by Prony brake or by the Hopkinson test. Dynamos can be run on a water resistance tank provided for the purpose. To provide a suitable range of voltage a double-ended motor-generator is placed near the test-bed having direct current dynamos at each end and a three- or six-phase motor at the centre. The motor is also provided with an ordinary D.C. commutator, so that a particularly wide range of currents and voltages can be obtained.

The whole establishment affords a remarkable example of the way in which the application of electricity on board ship has brought about a remodelling of engineering works organisation.

ELECTRICAL ENGINEERING AT THE MINING EXHIBITION

IN view of the very rapid increase in the number of collieries and other mines where the advantages of electrical working are being realised, it is not to be wondered at that the Mining Exhibition, which was opened on Saturday last at Olympia, by Lord Strathcona, should contain a good deal of interest to the electrical engineer. We cannot, however, refrain from expressing a slight sense of disappointment in the degree in which some of the heavier branches of electrical mining engineering are represented, and the entire absence from the list of exhibitors of a number of British firms whose work in the provision of electric power equiments to mines, at home, in the Colonies, and abroad is well known. The important subject of main shaft electric winding, which, in spite of its critics, is already taking considerable hold in the collieries of South Wales and other districts, is entirely unrepresented, and of the special forms of switchgear for mining work which have been developed by several of our leading manufacturers, but little is to be seen. The application of electrical power to collieries is a field where much remains to be done, and it is to be regretted that the colliery manager who comes to Olympia to see the latest developments in this direction will find so few of the firms who have specialised in this class of work adequately represented. As we shall see, there are one or two bright exceptions in the shape of exhibits by electrical firms who are more particularly identified with the applications of electricity in mines, and certainly there is a good and representative display by the makers of electrical coal-cutting machines.

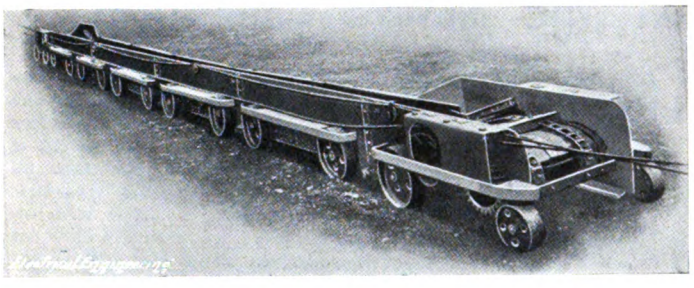
The stand of Messrs. DICK, KERR & Co., of Preston and Kilmarnock, contains a considerable variety of electrical material, and has been arranged to show, as far as space will allow, samples of all parts of electrical equipment required or used in connection with colliery, mining and quarry work in general, also some samples of light railway material used in connection with mines, collieries, and quarries. There are a number of samples of the various standard motors made by this firm, including a range of four sizes of direct-current motors up to 35 h.p., one fitted with a reduction gear, with the countershaft compactly arranged in the sub-base underneath the motor. A group of standard alternating-current motors are also shown, including both squirrel cage and slip ring types. Attention should also be drawn to a range of standard designs of crane motors, some of which are fitted with the firm's special design of automatic magnetic brake, which comes into operation immediately current is switched off the motor, and forms an attachment to the motor itself. There are also represented various types of motor starters. Particular attention is directed to the patterns specially designed to conform with mining regulations, including an oil-immersed auto-starter for squirrel-cage motors. The samples of "R" type controller shown are also well worth inspection. These are provided with the very efficient type of magnetic blow-out developed by Messrs. Dick, Kerr & Co., originally in connection with traction work. A specially interesting exhibit is a complete electric capstan, which, while being arranged on the usual lines of this type of machinery, has some novel features. The starter is of the contactor type. After the circuit nas been closed through the starting switch by depressing the starting pedal, the contactors automatically come into operation, cutting out resistance and starting the motor in the usual way; on the release of the pedal, or the operation of the overload device, the switch and the contactors come back to their normal position. With this arrangement it is impossible to start the motor too rapidly, and thus all starting switch troubles, due to carelessness of the operators, are eliminated. The starting switch itself is fitted with an overload and no-load release, and is provided with the blow-out fitting. The drive is through worm gear, and the other operation of the capstan follows the usual practice, with the exception that the capstan case is made watertight by a simple arrangement of the joints. Among the other apparatus shown is a complete standard motor panel, with a starter provided with a special slow movement gear. There will also be noted various contained in a flame-tight cast-iron case at the end of the engineering works at Kilmarnock, including a standard type tipping wagon, small turntable, set of points and crossings, and various samples of light railway track work with iron sleepers.

The HART ACCUMULATOR Co. have a most representative stand near the main entrance, upon which they show examples of practically every kind of secondary battery, from large central station cells down to small ignition accumulators. Several of the cells exhibited are provided with the company's new "Hexite" separator, consisting of a sheet of special material, which is claimed to prevent all possibility of short circuits between the plates, and thereof to diminish the cost both of inspection and maintenance. Among the types of cell shown are examples of portable batteries in lead-lined teak boxes, cells for automobile and marine propulsion in ebonite cases, special telegraph cells and ignition cells in celluloid cases. Attention should be called to a complete battery of 13 of the latest lighting type eleven plate cells, suitable for an installation of 112 10-c.p. 25-volt Osram lamps on a five-hour discharge, or 75 lamps for ten hours.

Messrs. MAVOR & COULSON, LTD., of Glasgow, have a large and interesting stand devoted principally to electrical mining work. Several examples of the firm's well-known "Pickquick" electric coal cutters are shown, as well as a compressed air machine. A particularly compact electrical coal cutter, only 15½ in. overall height is on view, driven by a single 12 b.h.p. continuous-current motor. Like all the coal cutters shown on Messrs. Mavor and Coulson's stand, these machines are of the revolving bar type. This particular machine, which has a cutter bar 3 ft. 6 in. long, is claimed to be the smallest long wall coal cutter on the market. The motor is, of course, entirely enclosed, and is of special construction. Its case forms a part of the frame of the machine. Although of the four-pole type, it is able to be extremely flat by having field coils only on the two side poles. An important feature in the construction is the fact that these poles complete with their coils can be removed from the side even when the machine is in position in a shallow seam and access to the top or bottom is impossible. The point of having every part of the machine accessible from the side has been kept in view throughout the design. The starter is contained in a flame-tight cast-iron case at the end of the machine away from the cutter bar, and is worked by a lever with an insulated handle. There are a number of points of interest in the arrangement of the gearing through which the motor drives the cutter bar. This is of the bevel type, and is entirely enclosed in the circular gear head. It is arranged so that the bar can be turned to any angle and can be easily altered in position for under or over cutting. The gear can be inspected by removing a cover at the end independently of the headroom available. A most ingenious device provides a to-and-fro movement to the cutter bar during its rotation. A cutter of somewhat larger size, driven by an 18 b.h.p. three-

Digitized by Google

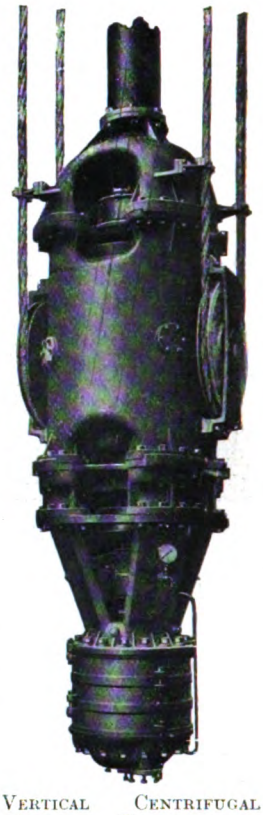
phase motor of the squirrel-cage type, is also shown. This is provided with a self-contained starter on the auto-transformer principle, with a switch of the barrel type, worked by a hand-wheel, and here again the starter handle is carefully insulated. The manufacture of these coal cutters has been standardised to such an extent that with the exception, of course, of the actual motors and starters, all parts, whether in continuous current, alternating current, or pneumatic cutters, are interchangeable. This greatly reduces the number of spare parts required for groups of collieries under the same management, where all these varieties are in use. The three-phase machine is shown adjusted for over-cutting, and, like the smaller cutter, is mounted on skids. It also embodies several improvements in the construction of the haulage gear, the drum of which is larger than formerly, and in general more substantial. One of these cutters is shown in the accompanying illustration.



The Gibb Carriage Conveyor (Messrs. Mavor & Coulson).

Another interesting object on the stand is an example of the Gibb patent carriage conveyor for underground use. This has been particularly designed for use in thin seams for drawing coal from the working face to the haulage road. The apparatus, as may be seen from the illustration, consists of a long, low jointed carriage provided with a mechanical end discharge operated by the same motive power which draws the carriage to and fro along the face. Each carriage comprises a discharging end, as many intermediate sections as may be required, and a back end containing the chain returning gear. The end discharge is effected by scrapers attached to a pair of endless chains returned under the bottom of the carriage. The gear is operated by a rope from an independently situated haulage gear engaging with a rope wheel mounted on the side of the carriage. While the carriage is travelling, the rotation of this wheel is prevented by a ratchet, but on arriving at the discharging position a simple trip arrangement releases the wheel so that it can drive the chains. Several motors specially constructed for mining work are shown, including a continuous-current flame-proof motor, in which special care is taken to seal the bearings. No attempt is made to render the motor gas tight, but a "chimney" is provided, with several layers of metal gauze separated by interspaces. The connections are taken in through pecial sockets filled in with cement. Another motor is a standard 100 h.p. three-phase induction machine with enclosed slip rings and a device whereby the slip rings are short-circuited and the brushes are lifted by a single movement of a lever. A separate continuous-current armature is shown, and also a special type of squirrel-cage rotor for mining work, which has the copper and connecting rings cast on, forming both electrically and mechanically a particularly sound job. The switchgear exhibited includes an enclosed motor panel for underground work, and a special enclosed starter. This is of interest, as being provided with a resistance composed of a number of units each composed of a helix of bare wire sprung into an asbestos tube but with no further insulation. The leads to the various sections of the resistance are threaded with glass beads, which form an excellent flexible insulation capable of standing a considerable degree of heat if necessary.

Messrs. Ernest Scott & Mountain, Ltd., of Close Works, Gateshead-on-Tyne, have some fine examples of electrical machinery for mining work on exhibition. Among these is a portable main-rope haulage gear with an 18-in. by 10-in. drum, suitable for a rope speed of 4 miles per hour. The whole of the gear is machine-cut, and the bearings are gun-metal lined throughout. The bedplate is steel, stiffened with angles and tie-bars, and bolted together. A powerful band brake, operated by a foot lever, and a jaw clutch, operated by a hand lever, are provided. The 5-h.p. motor drives the haulage-drum and gear through a raw hide or forged steel machine-cut pinion. This haulage gear is controlled by the special mining-reversing controller, with quick-make and break on every contact, a larger type of which is described and illustrated on page 115 of this issue. The contacts, which for this size of starter are not under oil, are contained in a water-tight case, with a single hand-wheel for starting, stopping, and reversing. An electrically-driven three-throw horizontal mining pump, capable of delivering 27 gallons of water per minute against a head of 200 ft., is exhibited, and a vertical centrifugal pump, capable of delivering 260 gallons of water per minute against a head of 300 ft., is also shown. The 40-h.p. continuous-current variable-speed motor is shunt wound for 500 volts, and rotates at 1,530 revolutions per minute. The motor and the four-stage centrifugal pump are coupled together and arranged so that the delivery water from the pump passes through a liner round the motor, through a breeches pipe on the top, and into the rising main, supported on this breeches pipe. The whole weight of the rising main, pump, motor, water column, &c., are taken by wire ropes passing round pulleys on the side of the motor. This arrangement has the following advantages:—(1) The weight of the rising main and water column is supported centrally on the motor, and as the unwatering proceeds it is only necessary to lower the pump down on its ropes and put additional lengths of piping at the top. (2) Considerably less space is taken up in the shaft. (3) It is very much easier to handle the rising main, as the ropes lowering the pump can be used as guides. (4) The pump, when the unwatering operations are over, can have brackets put into the foundations, and be permanently fixed on the foundations. The external appearance of the pump described above is exactly similar to that of the 300-h.p. pump illustrated, which is one of two 300-h.p. pumps supplied to the Kent Collieries, Ltd., and which is equipped with a three-phase squirrel-cage motor. Each of the two pumps supplied had its own generator, and the method of starting was to start up both motor and generator together, thus avoiding the necessity of complicated starting gear and slip-ring motors. Messrs. Scott & Mountain also exhibit a double-drum electrically-driven winding gear, designed for lifting an out-of-balance load of 1 ton from a shaft 500 ft. deep at a speed of 350 ft. per minute. Each drum is provided with a jaw clutch, so that the level of the cages may be adjusted, and a powerful band brake operated by a foot lever. In addition, a solenoid magnetic brake is provided so that should the current fail at any time the brake would come into action and hold the load. Depth indicators are provided, for showing the position of the cages in the shaft. The gear is driven by a 40-h.p. three-phase alternating-current motor mounted on the bed plate and driving through a machine-cut pinion. Other machines on the stand comprise a 50-h.p. continuous-current interpole motor of the semi-enclosed type, and a 190-K.V.A. three-phase generator.



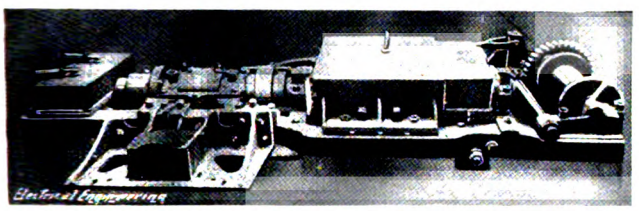
Vertical Centrifugal Sinking Pump, with 300 h.p. Water-cooled Motor (Ernest Scott & Mountain).

The Diamond Coal-Cutter Co., of Stennard Works, Wakefield, exhibit a number of their well-known "Diamond" longwall machines, both of the disc and chain types. The two-motor standard "Diamond" disc machine is driven by two motors wound for 500 volts, and each capable of developing continuously 18 B.H.P. A tramway type controller is used with magnetic blow-out and a separate fuse chamber. Both the switch lid, the fuse chamber lid, and the cable plug are automatically locked when the current is switched on, and cannot be opened or removed till the current is off. The 1908 type electrically-driven "Diamond" chain cutter is fitted with a 24-B.H.P. (direct- or alternating-current) motor. The gears are of steel throughout, are enclosed, and run in oil. The overall height of the cutter is 19″ and the length only 7′ 6″. This cutter is particularly suitable for short faces where a comparatively light and small machine is necessary and one that will cut its own way under the coal. A two-motor "Diamond" longwall chain machine is also exhibited, this being of the overcut type to remove a parting at any height, from 20″ upwards, from the floor. This machine is specially adapted for long faces, and will cut equally well in either direction. All the electric coal-cutters shown are fitted

Digitized by Google

with reversing switches, having magnetic blow-outs, and are designed to cut backwards and forwards. The disc machines are recommended for hard coal, and the chain machines for soft coal. The latter type is also preferable where polyphase motors are to be used as a lower starting torque is necessary. The two-motor disc machine described above is driven by two direct-current series motors connected in series. One motor is situated at either end of the frame. The firm also exhibit a section of their "Blackett" underground conveyer, the 8-h.p. 600-r.p.m. motor of which is concealed under the trough. The motor drives its conveyer through an epicyclic reduction gear, which reduces the speed in the ratio of 16 to 1. This conveyer is capable of discharging from 20 to 25 tons of coal per hour. Examples of the "Diamond" improved electric rotary mining drills, mounted on a patent carriage, are shown, and several types of switches are exhibited. Of these the standard self-locking 60-amp. gate-end switch and fuse-box is worthy of mention. This is fitted in a gas-tight box, and the switch cannot be closed until the lid of the case is closed; moreover, the lid cannot be opened until the switch is off.

Messrs. CLARKE, STEAVENSON & Co., LTD., of Barnsley, have on exhibition an example of the Clarke patent disc type coal-cutter



ELECTRIC COAL-CUTTER, MESSRS. CLARKE, STEAVENSON & CO.

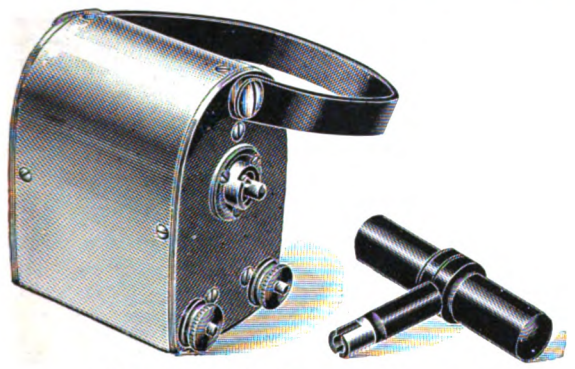
which presents several interesting features. The machine exhibited is driven by a 30-h.p. four-pole gas-tight continuous-current motor, forming part of the machine in the usual way. The cutting disc is driven through a double-thread bronze worm working into a steel worm wheel. The drive is transmitted from the motor through a flexible coupling, so that a certain amount of racking of the frame does not interfere with the alignment. A ball thrust of the Hoffman type is used. The starting switch, which has four steps, is situated at the cutter end of the machine. The feed of the haulage is worked by means of a rocking bar. The machine shown is of the standard size for working in a total height of 20 in.

Messrs. ANDERSON, BOYES & Co., LTD., of Motherwell, exhibit a longwall electric coal-cutter of the chain type, driven by a 30-B.H.P. continuous-current motor of the four-pole enclosed type with field coils on the two side poles only. A special feature of the motor is the provision of means for actuating the brush-rocker externally without opening the case, while the commutator is observed through a glass window at the side. The arrangement of the controller handle, which is sheltered from falling water by a steel roof, and is so constructed that it is impossible to switch on too fast or stop between steps, should also be noticed. A good deal of thought has been paid to the design of the haulage gear, the drum of which is driven through an epicyclic gear put into action by a brake drum, so that a very gradual start can be obtained after the machine is running and the feed stopped and restarted at any time without stopping the cutters. The main gearing is enclosed in a circular head, and is of the bevel type. A machine of the disc type, driven by a three-phase motor, is also shown, and an electric rotary drill mounted on a travelling carriage.

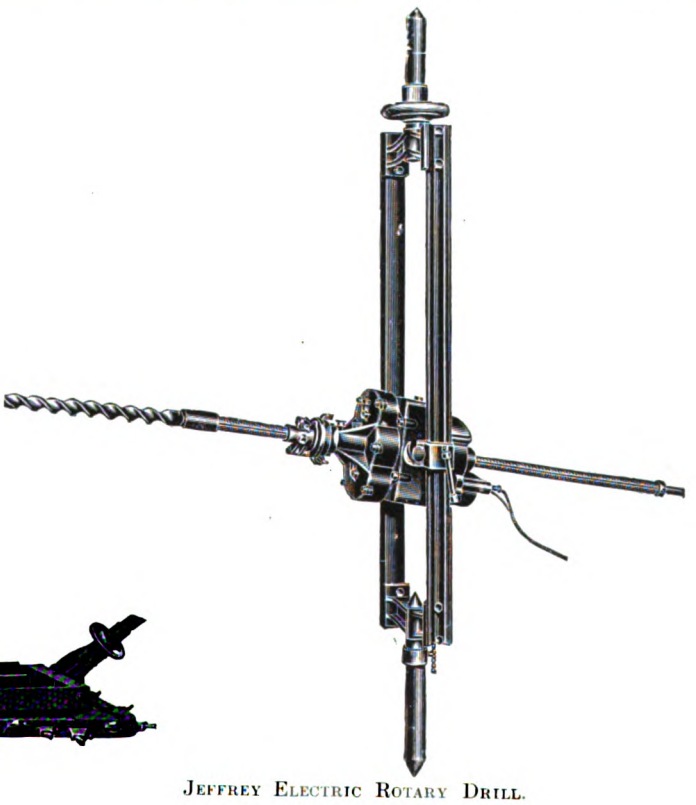
BELHAVEN ENGINEERING & MOTOR, LTD., exhibit an example of the "Clyde" electric disc coal-cutter. This is driven by a 35-h.p. motor through enclosed gearing running in oil. The total weight of the machine is about 45 cwt., and the extreme height from the skids can be kept down to 19½ in. or even 18 in. if necessary. Special care is taken in the lubrication of the centre pin of the disc, which is by forced feed. Ball races are provided to take the thrust of the bevel gears. The haulage feed is of special design, by which any cutting speed up to 4 ft. per minute can be obtained by moving a small lever when the machine is working. On the same stand are shown motors with the "Lacy" patent field winding, in which by a peculiar arrangement of dividing the field coils into sections, wound in opposite directions, a method of speed regulation can be obtained without resistances. Some further remarkable properties are claimed for this system.

An electric coal-cutter is shown by AUSTIN HOPKINSON, of Delta Works, Guide Bridge. The coal-cutters manufactured by this firm are of the longwall chain type, and have the jib so arranged that it can slew round while working to cut its way into the coal. Attention should be paid to the construction of the frame, which is of tough cast-steel, including the lower half of the motor case. The motor cases are split axially to allow of easy removal of the armatures. Worm gearing is used with ball thrusts, and the controller is oil immersed.

JOHN DAVIS & SON, LTD., of All Saints Works, Derby, have a very extensive exhibit comprising electric coal-cutters, drills, and blasting apparatus, and also a large selection of telephones, signal bells, &c., for mining work. The electric coal-cutter illustrated above is driven by a continuous current motor rated at 21 b.h.p. The height of the machine is 21 inches, the length 10 ft. 5 in., and the width 3 ft. 2 in. It weighs 27 cwt. To



"DAVIS DERBY" MAGNETO EXPLODER.



JEFFREY ELECTRIC ROTARY DRILL.

JEFFREY ELECTRIC HEADER.

Digitized by Google

suit the hardness of the material to be cut, a choice of three speeds may be made. With the standard or fast feed, 3½ minutes are occupied in making a cut 6 ft. under; with the medium feed the operation is performed in 7 minutes; and with the slow feed, 9 minutes. The cutter-head makes its return journey in 30 seconds. The cutting chain consists of a number of tool-holders alternately holding the cutters horizontal, pointing upwards, and pointing downwards. The "Jeffrey" electric drill, also illustrated, is designed especially for drilling in hard materials. The drill feed-screw passes through the armature spindle which is hollow. By this means a well-balanced drill is obtained, whereas with other arrangements the motor must be above, below, or on one side of the feed-screw. A pinion with 25 teeth surrounds the hollow armature shaft, and engages above and below with 65-tooth wheels. Mounted on the same shaft with these wheels are the pinions of the second reduction set of gearing. The speed of rotation of the auger may be varied between 106 and 310 r.p.m., and the forward feed may be varied from 10 to 62 inches per minute. The motor is a 3 h.p. 4-pole series-wound continuous-current motor, and is contained, together with the starting switch and gearing, in a damp- and gas-tight case. A friction band is provided, with a wing nut and bolt for adjusting the pressure, to allow the feed bar to revolve with the auger without progressing, should it encounter any foreign substance in drilling, and so avoid unnecessary strains. The supporting frame is constructed of two "channel" bars with cast steel top and bottom yokes. The weight of the drill, with continuous-current motor complete for a six-foot seam, is 288 lb. Each drill is provided with 50 ft. of flexible concentric leather-covered cable. The third illustration is that of a "Davis Derby" magneto exploder for firing shots in mines. These can be obtained for either high or low tension firing. In a high tension fuse the explosion is caused by the ignition of a chemical compound; in a low tension fuse the explosion is caused by heating a fine iridio-platinum wire to a red heat and thus firing the priming. The current, whether high or low tension, is generated by giving the handle of the exploder a half-turn. The circuit is not closed until the half-turn is completed, when the armature has reached its maximum speed. A steel pin comes up against a stop at the completion of the half-turn, and prevents further turning. The handle, which is detachable, works on a shaft supplied with a ratchet in front of the gear wheels. Other types of exploders with revolving handles and press-buttons are exhibited by this firm A large selection of telephones and bells in water-tight and gas-tight cases are shown, and also some electric lighting devices with a magnetic lock for preventing a lamp from being opened underground.

Messrs. BERRY, SKINNER & Co., of Suffolk Works, Birmingham, have an extensive display of various patterns of their pull on and push off switches such as we described in some detail in connection with the collective exhibit of the electric supply companies of London at the Franco-British Exhibition. These are particularly suited for mining work, especially in the form combined with interlocked plugs (see ELECTRICAL ENGINEERING, July 2nd, page 26). A novelty on the stand is an electric miners' lamp, worked by a primary battery, which is arranged entirely without a switch to light up when placed one way up, and be extinguished by causing the electrolyte in the cells to drain off by inverting the lamp. Each lamp contains two of these reversible cells in series. They are entirely non-gassing, and can be sealed up. The battery is capable of maintaining the lamp alight for 12 hours continuously without requiring intervals for recuperation, and does not weigh more than about 4 lb. The whole is strongly made, and is contained in a metal case with the end containing the lamp secured by a bayonet joint. A lamp on a similar principle for surface use is also shown. This can be provided with an extra lamp on a flexible cord with a combined switch and plug.

An interesting item on the stand of the INGERSOLL RAND COMPANY, of 165 Queen Victoria Street, is the Temple-Ingersoll electric air drill, which, although in considerable use in the United States, has not, we believe, been previously exhibited in this country. As will be gathered from the illustration, this apparatus consists practically of an ordinary compressed air percussion drill, actuated by a small electrically-driven compressor on a truck. A section of the drill itself is given in the accompanying drawing. The main advantage claimed for this system of drilling is that it combines the economy of electrical as against pneumatic transmission, with the simplicity and cushioned blow of the air drill, and only requires about 1/5th of the power of the latter. The cylinder is divided into two parts, each with its own piston. Each piston is driven by the air from one air cylinder of a small electrically-driven air pump without valves by means of a separate tube. The two drill pistons run synchronously with the air pump pistons, and

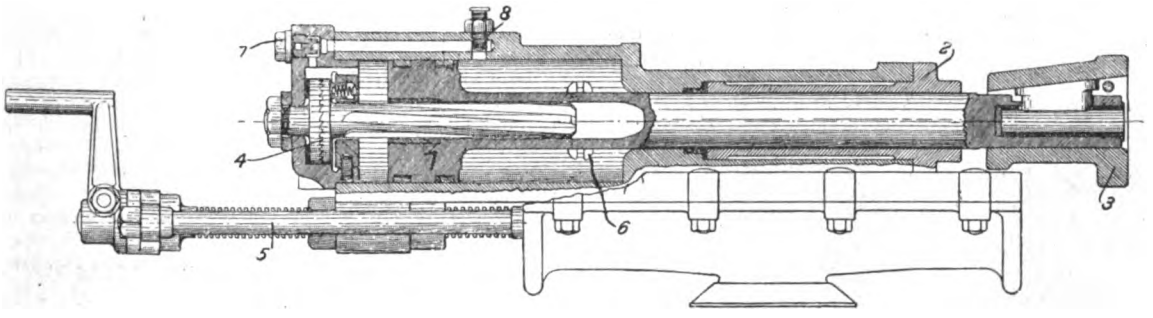
the quantities of air in each half of the drill cylinder act as air cushions at the same time. The air is always the same, and is saturated with oil so as to act as a lubricant. This drill is exceedingly simple, and requires very little repairing. The output or speed of the strokes can easily be varied by means of the motor driving the air pump. It requires, of course, more room than the purely electric drills, on account of the air pump, although this is very compactly arranged, but is quite suitable for large stopes and easy tunnelling work. The outfit shown is driven by a 2 h.p. 3-phase motor, and is intended for holes 6 to 8 ft. deep.



SECTION OF WORKING CYLINDER OF INGERSOLL-TEMPLE DRILL.

The most interesting exhibit on the stand of Messrs. R. H. LONGBOTHAM & Co., of Wakefield, is a complete portable electric haulage gear, shown in motion. This is of a size suitable for lifting a dead weight of 2½ to 3 tons, or as a haulage gear proper, of drawing a load of 14 tons up a grade of 1 in 6 at a speed of 156 ft. per min. The whole apparatus, including motor, controller, &c., is mounted on standard gauge wheels. The drum is 4 ft. in diameter, and capable of holding 1,400 yards of ¾ in. rope; it is driven through treble reduction gear by the motor, and can be thrown in and out of gear by a three-jaw clutch. The motor is of the three-phase induction type of the Phœnix Dynamo Manufacturing Co., and is rated at 30 b.h.p. at 720 r.p.m. on a 550-volt 50-cycle circuit. It is controlled by a Phœnix tramway type controller.

Messrs. HEAD, WRIGHTSON & Co., of Stockton-on-Tees, have an imposing stand, on which is shown a large working example of an electrically-driven screening plant, driven by a 7 b.h.p. induction motor, manufactured by the British Thomson-Houston Co. This apparatus is 34 ft. long, and is part of an order for a Yorkshire colliery, and consists of a "Marcus" patent conveyor. This is formed of a trough which is supported on line rollers, and receives a peculiar to and from motion from the driving mechanism with the advance and return of different speed. The material is thus caused to travel intermittently along the trough. The conveyor shown is of a size to deal with 100 tons per hour, and the main shaft runs at 70 r.p.m.

Messrs. GWYNNES, LTD., have an exhibit chiefly relating to electric pumping. We particularly noticed an electrically-driven seven-stage high lift centrifugal pump, directly coupled to a continuous current motor, running at 1,900 r.p.m., and capable of delivering 180 gallons per minute against a head of 500 ft. This is a particularly compact set, and well illustrates the possibilities of electrical pumping.

Messrs. HANIEL & LUEG, in addition to some other interesting exhibits not connected with electrical working, have on view a beautifully finished scale model of a large slow speed electrically-driven reciprocating twin mine pump. The motor is of large diameter, running at 92 r.p.m., and the rotor is mounted direct on the crank shaft between the two cranks. The actual pump of which this is a model, is for the Prussian Government mines, and has a capacity of 660 gallons per minute from a depth of 2,100 ft.

The stand of Messrs. DAVIDSON & Co., LTD., of Belfast, contains an excellent example of the way in which electric power is applied to the ventilation of mines in the shape of a 49-inch "Sirocco" mine fan, with a capacity of 26,000 cubic feet of air per minute against a head of 3 inches of water. It is direct-coupled to a 20 b.h.p. continuous-current 220-volt motor, manufactured by Messrs. Mather & Platt, of Manchester, which drives it at 420 r.p.m. The switchgear for the motor is all contained in a substantial gas-tight iron case, suitable for use under ground. The panel comprises voltmeter, ammeter, starting switch, field regulating switch, D.P. main switch, and fuses, and is also supplied by Messrs. Mather & Platt. Some other smaller fans are also shown.

Messrs. HEENAN & FROUDE, of Worcester, also devote most of their space to fans of a type specially suitable for electrical driving. A large "Heenan" mine fan, with single inlet, and fitted with Evase chimney, is shown arranged for belt driving, although of a type easily adapted for direct coupling. It is capable of discharging 40,000 cub. ft. of air per min. against 3 in. of water pressure when running at 340 r.p.m. Several smaller fans, both of the Heenan and Shiele types, are also shown.

Messrs. REAVELL & Co., LTD., of Ipswich, exhibit a number of examples of their well-known air compressors specially designed for electric driving, including a novelty in the shape of a very compact compressor intended for use as a sub-station cleaning set. This is arranged with handles so that it can be carried by two men. The weight is 128 lb. The motor is rated at ¾ B.H.P., and is directly coupled to the compressor; a very neat crank motion drives the two opposed cylinders without connecting-rods, and the crank-pin and main bearings are oiled from a single oil well. When carrying, the delivery hose is coiled round a wooden cylinder, the inside of which accommodates the flexible electrical lead. The larger compressors shown are mostly of the four-cylinder type. One of these, which is gear-driven by a 33-B.H.P. motor, runs at 250 r.p.m., and delivers 170 cubic ft. of air per minute against a pressure of 90 lb. per sq. in. A direct-coupled compressor, running at 400 r.p.m., is also shown, which has a capacity of 95 cubic ft. of air against 70 lb. per sq. in. and is driven by a 19-B.H.P. motor. One or two other compressors are shown, and in the centre of the stand is a complete steam generating set, consisting of a single cylinder enclosed Reavell double-acting engine, running at 700 r.p.m., direct coupled to a four-pole generator.

The exhibits of PETER BROTHERHOOD, LTD., of 53 Parliament Street, S.W., of an electrical nature include a very compact generating set, consisting of 12-kw. Siemens continuous-current four-pole dynamo for an output of 150 amperes at 80 volts direct-driven by a single-cylinder Brotherhood engine running at 650 r.p.m. Attention should also be drawn to a small electrically-driven air compressor, suitable for cleaning electrical machinery, &c., in generating stations and sub-stations. This is a single-cylinder water-cooled compressor driven by a Westinghouse motor through a raw hide pinion, which gears into an internal ring of teeth inside the rim of the overhung flywheel. The whole is mounted on a single bed plate, which contains the cooling-water tank.

Messrs. BROWETT, LINDLEY & Co., LTD., of Patricroft, Manchester, exhibit one of their latest standard enclosed forced lubrication three-crank three-cylinder triple expansion double-acting vertical steam engines, arranged to run at 375 r.p.m., and suitable for driving a 350-kw. dynamo as a normal load when working condensing with 150 to 180 lb. steam pressure at the engine stop valve. It is also capable of giving 25 per cent. overload. This engine is fitted complete with a centrifugal shaft governor, controlling the speed by acting direct on a throttle valve, and is provided with forced lubrication to all bearings, &c.

The STIRLING BOILER Co., of 25 Victoria Street, show working models constructed to exhibit the way in which the water circulates in their well-known water-tube boilers.

Messrs. E. GREEN & SON show models of their well-known economisers for applying the waste heat from the furnace to raise the temperature of the boiler feed. These models are very complete, and the scraper gear is driven in each case by a small electric motor.

Messrs. HEINRICH LANZ, of Mannheim, exhibit examples of portable and semi-portable self-contained engine and boiler sets, or "Locomobiles," with Lentz patent valve gear. The engines of these sets are of the horizontal type, mounted on the top of tubular boilers, combined with superheaters, and in addition to the advantages due to compactness and portability, a very high degree of economy of fuel is claimed.

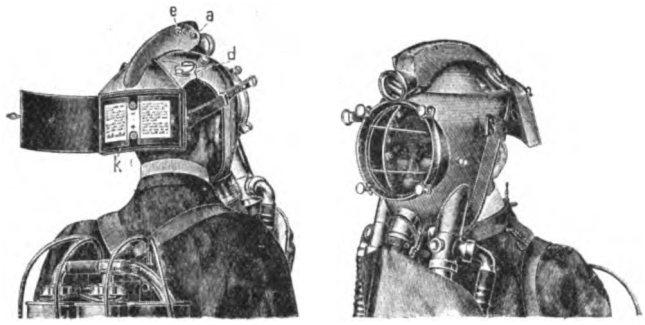
The stand of Richard Jacobson, of 11 Water Lane, Great Tower Street, is devoted to the well-known Draeger rescue apparatus and smoke helmets. A recent addition to the equipment is a special new form of electric head lamp for fixing on these helmets. This lamp is not connected by flexible wires to the battery, but is arranged all in a piece to fit over the top of the helmet, with the accumulator in its metal case forming a neck protector at the back. The advantages of a head lamp such as this over a hand lamp are obvious. The whole apparatus is readily removable from the helmet, and only weighs about 2 lb. It is said this extra weight, rather than being a source of dis-



Back view, showing accumulator case open. Front view.

e—Switch.
k—Accumulator.

Draeger Electric Helmet Lamp applied to Rescue Dress.

comfort, improves the balance of the helmet. The 4-volt battery consists of two special curved cells, and is easily taken in and out from the back. They are of sufficient capacity to keep a 3-c.p. lamp alight 2½ hours, or a 1½-c.p. lamp for 5 hours. Considering that the breathing apparatus only carries oxygen for about two hours, this capacity should be quite sufficient. The lamps are of the metal filament type. The general arrangement of the lamp on the helmet can be seen from the accompanying illustrations. Special charging boards for the accumulators are supplied. A hand accumulator lamp burning eleven hours is also shown.

E. Thomas & Williams, Ltd., of the Cambrian Lamp Works, Aberdare, have several forms of electric lighters for miners' safety oil lamps on exhibition. The "Cambrian" underground safety relighter is worthy of mention, as it is intended for re-lighting lamps underground in the presence of fire-damp with perfect safety from explosions. There are no batteries or accumulators, the current being generated by a magneto-generator in the base of the apparatus. The method of lighting is as follows :—The lamp is placed on a plate at the bottom of the lighting chamber, and two studs on the plate are brought in contact with two studs on the base of the lamp, which lead to a spark gap placed over the wick of the lamp. When the lid of the chamber is closed the handle of the magneto is given one or two sharp turns, and the spark at the gap ignites the wick. The lighting chamber is of heavy construction to withstand the force of any internal explosion, should this take place. A locking gear prevents the generation of current while the contacts are exposed to the atmosphere of the mine. The lighting chamber is, of course, perfectly gas-tight.

The Wolf Safety Lamp Co., of 37 York Place, Leeds, have several examples of their miners' safety lamps with magnetic locks. They also exhibit an electric miner's lamp. The lamp itself is a 2-volt Osmium lamp, taking about 1 ampere and giving from 1 to 2 c.p. It is enclosed in a strong glass case, fitted to the lamp-carrier in an air-tight manner. The lamp case is made of tinned sheet steel, painted with an acid and rust-resisting composition, and the closing ring is made of an alloy of aluminium. The lamp can be only unlocked magnetically. The single-cell accumulator is enclosed in a celluloid case, and will keep the lamp burning for twelve hours continuously. The lamps last over 800 hours, but the filaments are very fragile when not burning, and it is recommended to keep the lamps alight from the time of handing out to the time of handing in to the lamp-room. The lamp weighs 4 lb. complete.

Messrs. Ackroyd & Best, Ltd., of Morley, near Leeds, have a good selection of their mining specialities on exhibit. Amongst these are their electric relighters, which are fitted with accumulators and induction coils, differing in this respect from other types, which are mostly fitted with magneto generators. The miners' safety oil lamps supplied by this firm are fitted with an automatic locking arrangement. To unlock the lamp it is placed over an electro-magnet, which withdraws a lock-bolt and permits the unscrewing of the base of the lamp. This firm also exhibits a new form of underground relighter, which consists of two heavy cast-iron cylindrical chambers. The lower chamber contains the accumulator and induction coil, and in the upper chamber the lamp is placed. Closing the upper chamber automatically causes the sparking at the ignition gap to take place. The chambers are flame-proof, but there is a narrow space between the cylindrical-revolving walls of the chambers through which the gaseous products of an explosion can harmlessly escape. The passage of the gases between these cold iron walls cools them sufficiently to prevent any danger of explosion outside.

The Grondal Kjellin Co., Ltd., of 20 Abchurch Lane, E.C., exhibit a model of a Kjellin induction steel furnace similar to that illustrated on page 18 of our issue of July 2nd. The model exhibited, however, has not the renewable hearth with which the latest types are fitted. Samples of steel produced in the Kjellin and Röchling-Rodenhauser electric induction furnaces are also exhibited. Samples of electrically-melted steels, including Diamond-Tungsten and Chrome steels are shown by Messrs. Sybry, Searls & Co., Ltd., of Cannon Steel Works, Sheffield, who produce all these classes of steel from the raw Swedish iron by means of the Kjellin furnace.

The Cambridge Scientific Instrument Co., Ltd., have a stand on which are exhibited a selection of scientific instruments used in metallurgical processes. Porcelain-tube pyrometers and instruments for taking readings from the same at regular intervals are shown. Some examples of the latest types of millivoltmeters are also to be seen.

CATALOGUES AND PAMPHLETS RECEIVED

ALMANAC.—Messrs. W. T. Glover & Co., Ltd., have issued their well-known almanac for the twelve months commencing July 1st. The sheet for each day is either embellished with a picture showing applications of Glover cables or appealing to one's sense of humour, or contains an interesting quotation from electrical literature. The almanac is arranged so that it can either be hung on the wall or stand on a table.

BRANCH SWITCHES, PLUGS, &c.—A collection of lists from Messrs. A. P. Lundberg & Sons illustrates a number of patterns of switches and plugs suitable for a variety of purposes. The "Pivot" pattern tumbler switch, both in its single and two-way pattern, is listed in a number of forms, including the locked cover, removable key, and flush types. The "Pivot intermediate" switch is also of the tumbler type, and is used in conjunction with two-way switches in cases where it is desired to control groups of lights alternatively from more than two points, for example, where it is desired to turn all the lights on a staircase on or off from any floor. Another leaflet deals with combined switches and plugs of the two- and three-pin type for special purposes.

ELECTRIC COOKING APPARATUS.—A new leaflet from the Simplex Conduits calls attention to several new patterns of kettles and saucepans which are put on the market at very low prices. One of these is a neat brass kettle, which will boil 1½ pints of water in 9 minutes with an energy consumption of 500 watts. We understand that some reductions in price are made to agents ordering these kettles in lots of not less than a dozen.

ELECTRICAL PLANT.—A booklet has been issued by Messrs. Crompton & Co., Ltd., containing a series of reproductions of photographs of their Chelmsford works, representative examples of plant manufactured therein, and installations equipped with Crompton machinery, showing the wide range of the company's activities.

GAS ENGINES.—A leaflet from Messrs. E. S. Hindley & Sons calls attention to the advantage claimed for the firm's well-known pattern of vertical multicylinder gas engine, running at high speeds, and suction gas plants.

INSULATING VARNISH.—A pamphlet from Messrs. Turners & Manville, Ltd., of 5 Lloyd's Avenue, E.C., describes the purposes for which the preparation known as "Voltax" is suitable. This anticorrosive varnish claims to combine the qualities of transparency and elasticity with excellent waterproofing and insulating properties. A special quality is made for coating armature, field, or transformer coils, and other uses include prevention of corrosion of metal work, both under or above water, and the formation of a water, acid, and alkali proof covering for the interior and exterior decoration of car bodies. The dielectric strength is given as 3,000 volts per mile.

TELEPHONES.—A compact and well-arranged catalogue from the Sterling Telephone & Electric Co., of 200 Upper Thames Street, contains particulars of a number of patterns of the well-known "Sterling" telephone, including direct-acting short-distance sets, without induction coils, battery call telephones for longer distances, central battery equipments, mining telephones, various patterns of magnets, call telephone, and a long series of intercommunication sets. A few typical switchboards are illustrated, and particulars of bells, batteries, and other accessories are given.

ANNUAL CONGRESS OF THE TRAMWAYS AND LIGHT RAILWAYS ASSOCIATION

ON Thursday and Friday the Annual Congress of the Tramways and Light Railways Association was held at the Franco-British Exhibition. The Duke of Argyll, who is President of the Association, received the members in the Congress Hall of the Exhibition, and after a few words of welcome, in which he explained the absence of the Chairman of the Council, the Hon. Arthur Stanley, M.P., he called on Sir Clifton Robinson to deliver his address on "Tramways of the World." We publish this address in slightly abbreviated form below.

TRAMWAYS OF THE WORLD.

By Sir J. CLIFTON ROBINSON.

Horse tramways, as we all know, have existed in one form or another for half a century or more. Stone or iron tracks offering a smooth surface to the wheel have been used from a remote period, until from those primitive designs we have advanced to the grooved rail tramways now found in every quarter of the globe. The first use of rails and flanged wheels on roads appears to have been in the United States, where necessity evolved them when ordinary roads and streets were non-existent or impassable. In 1860 my old chief, George Francis Train, introduced the pioneer street railway into Great Britain, at my native town of Birkenhead, and followed it with extensions of his system in London, South Staffordshire, and Darlington. All these were failures, mainly owing to the use of the American type of step rail then in vogue, which interfered seriously with other vehicular traffic. The next experiment was made in Liverpool with the so-called crescent rail, in 1865, and this town was the first in England to obtain Parliamentary powers for tramways, which it did after lengthened opposition in 1868. The first section was opened in November, 1869, which begins modern tramway history in England. London, Glasgow, and Dublin followed almost immediately, and Parliament, after an exhaustive inquiry, passed the General Tramways Act of 1870, to "facilitate the construction and working of tramways" in Great Britain. As we know to our cost, the Act has in many ways hindered, instead of facilitated, development. The Act enabled local authorities to promote and own tramways, but expressly denied the right to operate them. It conferred upon them powers of compulsory purchase after a period of 21 years on terms which were subsequently construed as "scrap iron" price. In nearly every case the acquisition of the lines by a local authority has been followed by municipal working. The first real advance in mechanical traction was the invention of the cable system by A. S. Hallidie, and the first line was laid down in Clay Street, San Francisco, in 1873. Other routes rapidly followed, and it was then found that, in addition to working successfully on steep gradients, the cable system was more economical in operation than anything hitherto known. Its adoption in Chicago, New York, and other large cities demonstrated that the system was equally suitable for level roads, and that the heavier the volume of traffic the lower the expense per car mile became. Outside the United States the first cable line was opened in Dunedin, New Zealand, in 1882. I was associated with others in the construction of the first cable tramway in this country—that at Highgate Hill, inaugurated in 1884, with great *éclat*, by the Lord Mayor of London, and which is at length about to be converted to electric traction.

Excellent as the cable system was in practice, it had its drawbacks in the way of large capital expenditure, extensive road excavation, and the movement of dead-load mechanism in the conduits under the street. Where the traffic was of reasonable magnitude, the extremely low working expenses more than offset the capital cost, but the latter rendered it impracticable for suburban and outlying districts. There was also a limit to the length of cable which could be profitably utilised, so that for a large system power houses had to be multiplied indefinitely. Some method combining greater flexibility and power of expansion was needed, and traction engineers longingly turned their eyes in the direction of electricity.

Sir W. Siemens exhibited the first electric railway model at Berlin in 1879, and the first line for public traffic was opened at Lichtenfelde in 1881. Edison and S. D. Field constructed a short electric railway at the Chicago Exhibition of 1883, and in the same year Magnus Volk laid down a short electric line on the beach at Brighton. The inauguration of the Giant's Causeway electric tramway took place also in 1883; the initial electric conduit tramway was opened at Blackpool in 1884, and the Bessbrook and Newry line a year later. In January, 1893, the first electric overhead trolley line in Great Britain was opened at Roundhay Park, Leeds. The poles and overhead construction were pronounced hideous, but the speed and ease with which the cars moved proved a revelation. This demonstration was quickly followed by the conversion of the South Staffordshire steam tramways, but hardly had these lines got under way when the æstheticism of a section of the British public was up in arms at the outrage thus perpetrated, and, as all sorts of dangers were imagined, Parliamentary inquiry, involving tedious delay, was instituted. The outcome was the promulgation in 1894 of Board of Trade Regulations for the protection of existing interests, and these rules, remodelled from time to time, are still in force. They have no doubt increased the construction cost, but on the whole have encouraged a type of installation and equipment unsurpassed if not unequalled in the world, and there is no doubt that it is due in no small measure to the efficient and rational influence exerted by the Board of Trade over our railways and tramways, that we owe our relative immunity from the appalling accidents so frequent in other countries.

About this time the famous decision was given by the House of Lords that the price to be paid by a local authority in exercising its powers of purchase under Section 43 of the Tramways Act was the cost of construction minus an allowance for depreciation dependent upon the condition in which the tramways were when acquired. Something of the kind had been feared, and tramway companies had become chary of investing capital in electrification. When the House of Lords' judgment encouraged a rush of local authorities to enter upon schemes of tramway ownership, all hope of raising capital by private enterprise for the adoption of the new method of traction had to be practically abandoned. A few of the stronger and more progressive companies, in enjoyment of considerable terms of unexpired tenure, and strong in the faith that was in them, came to terms with the local authorities and succeeded in pressing forward the realisation of electric traction.

When I returned to this country, simultaneously with the reconstruction and electrification of the Middlesbrough, Stockton, and Thornaby tramways, I found myself engaged in what for long seemed hopeless, or at least fruitless, missionary efforts in pioneering electrical traction in London. From 1894 to 1901 the struggle waged, and resulted in the establishment of the London United Tramways as you see them to-day, a well-equipped system extending to 56 route miles. When, before the London County Council, I advocated the introduction of the overhead trolley at Shepherd's Bush, I was threatened, in effect, that if the London United Company dared to put up posts in the streets to carry overhead wires, the people would rise and tear them up by the roots. Confronted with that extraordinary attitude, we had perforce, for the moment, to accept the conduit system at Hammersmith. But when the Borough Council realised that its streets were to be used for experiment, resolutions were immediately passed, with the result that in the next Session of Parliament the objectionable conduit clause was rescinded in favour of the overhead trolley, by means of which system the London County Council are to-day successfully conveying thousands of grateful passengers to and from this great Exhibition.

In 1901, on the eve of the opening of the first electrified section, the Royal Observatory at Kew urged the dangers with which our electric current threatened its delicate instruments. The Observatory opposition was disposed of, and for ever removed from the path of electric tramway development. From first to last I have had to negotiate with thirty different public authorities, and the price of their consent to the construction of our tramway—in compulsory widenings, in capitalised wayleaves, and otherwise—has aggregated a round million sterling. That is a heavy handicap, but in spite of it we have earned an average of 5 per cent. in the six years of the electrical development period during which we have carried no less than 300,000,000 passengers.

The largest companies in the country still in the hands of private enterprise are the British Electric Traction, the Dublin United, the Cork Electric, the Lancashire United, and the London United Tramways. Apart from these companies, the whole of the large systems in Great Britain are now worked by municipalities. The development of municipally worked electric tramways came with a great bound, as all the conditions were favourable. Companies could be bought out at a low price, capital could easily be raised at low interest on the security of the rates, and, above all, the tenure was perpetual. Thus, in the closing years of the last century, companies were ruthlessly frozen out, and the lines reconstructed, extended, and electrified. Many of the municipal tramways in medium-sized and smaller towns are in financial straits, because low fares, high wages, interest and sinking fund render it difficult to keep the accounts on the right side. Depreciation allowances, which

Digitized by Google

have become a burning question in connection with municipal and private enterprise alike, are frequently inadequate and sometimes non-existent. In the large cities municipal tramways are regarded as prosperous, and with the enormous traffics obtainable in densely-populated communities, it could hardly be otherwise, unless there was gross extravagance or mismanagement.

The London County Council tramways require separate mention. Owing to the extensive adoption of the conduit system a large capital expenditure has been necessary, and to this must be added the price of the old horse tramways taken over from the companies. At present the total cost represents over £60,000 per route mile of tramway, and about half the mileage consists of horse lines still to be electrified. When all these have been converted, the cost per mile over the completed system will be considerably higher. Although the lines are operated through what are probably the most congested districts in the world, and the cars carry about a million passengers per day, there is only a modest surplus for the reserve fund after paying working expenses, and the enormous annual capital charges. It is only fair, however, that two features common to other similar undertakings should be referred to. First, the horse lines, partly owing to dislocation of traffic during reconstruction, are operated at a loss, and this, it may be assumed, will improve concurrently with the work of electrification. Second, the debt charges are not equated as in other towns. The result is that, instead of a uniform charge over the whole period of the currency of the loans, interest and redemption on the whole sum borrowed is paid from the first, and the amount of interest paid per annum diminishes every year as the capital is paid off. Thus, even though matters were not to improve, the financial position should get better every year provided adequate amounts are set aside as a reserve for depreciation and allowed to accumulate, a matter which, as we know, is at the moment seriously exercising the minds of all concerned.

As I have said, the London County Council have recently departed from their strict adherence to the underground conduit, and have now adopted the overhead trolley system. Many millions might have been saved to London in construction cost alone, had that repentance come earlier, but the County Council adhered so long to its antipathy to the trolley that the borough councils followed suit by logically vetoing the overhead system. In the hope of escaping the heavy cost of the conduit and the veto of the borough councils, the County Council is now considering a surface contact system, which they have just put into tentative operation.

There appears no prospect of extensive development of the conduit, or of any surface contact systems, save in places where from æsthetic considerations, real or affected, as in the case of our good friends and neighbours the Richmond Corporation, overhead wires are prohibited. The accumulator system has been dead for years, and for tramway purposes displays little or no symptoms of resuscitation.

I have not mentioned the Light Railways Act of 1896. To a considerable extent it has been taken advantage of for the construction of electric tramways, and the procedure is quicker and somewhat cheaper than that of proceeding by Bill. The veto of local authorities has not to be encountered, but against this an existing railway company may veto a proposal on the ground of competition, and a Light Railway Order will not be granted for a line which would be wholly within the area of one local authority. The Act is gradually becoming a dead letter, and no great increase in the number of applications under it can be hoped for till it has been amended.

I have already touched upon the greatest stumbling block in the way of tramway promotion. That is the power of veto vested in local authorities by the Standing Orders of Parliament. Great hopes were entertained that good results might follow the recommendation of the Royal Commission on London Traffic in 1904, that the veto should be modified if not altogether abrogated. My view put before the Commission may be summarised in the words:—"I saw no reason why rules, regulations, or even Standing Orders that had become out of date should not be scrap-heaped in a similar manner as mechanical appliances that had become obsolete."

Our labours in pressing this very necessary reform have not been altogether in vain, and this session, in connection with the project for linking up our West London, Middlesex, and Surrey lines across King Edward VII. Bridge, the Committee of both Houses unanimously disallowed the veto of the two County Councils, and permitted the Bill to proceed. This is merely an indication, but, to my mind, a hopeful one. Ages ago, I verily believe, the warden of the keys of progress fell asleep in our ancient and Imperial Houses of Parliament, and in his slumber relinquished all of the bunch from his hand but the one key that unlocked the door to those endeavouring to solve the problem of street traction. No one has dared to lift that mighty hand, but there are signs and portents, slight though they be, that the monster is moving in his sleep.

We have every encouragement in the enormous development of tramways in this country within recent years, and I quote here some figures from the last Board of Trade returns, which were published in the spring, giving a comparison of totals with 1902, when electric traction was beginning to get into full working stride.

	1906-7.	1902.
Total capital expended ...	£64,092,091	£31,562,267
Length of route open ...	2,394 miles	1,484 miles
Number of horses	7,378	24,120
Number of locomotives ...	148	388
Number of electric cars ...	10,369	...
Number of non-electric cars	1,377	...
Number of both kinds of cars (not separately distinguished)		7,752
Number of passengers ...	2,454,807,487	1,394,452,983
Board of Trade electric units used...	369,362,473	...
Gross receipts	£11,849,175	£6,679,991
Working expenditure ...	£7,365,762	£4,817,873
Appropriation of net receipts—		
Interest or dividend ...	£1,828,966	...
Repayment of debt ...	£803,325	...
Relief of rates	£297,456	...

The 2,394 miles of route open in 1906–7, reckoned as single track, amounts to 3,850 miles.

These figures for 1906–7 relate to 318 tramway undertakings in the United Kingdom, of which 179, having a route length of 1,571 miles and a capital expenditure of £41,735,547, belonged to local authorities, and 139, having a route length of 823 miles and a capital expenditure of £22,356,544, belonged to companies. Out of the total length of 2,394 miles, 2,195 miles were worked by electricity, 64½ miles by steam, 25¾ miles by cable, 4 miles by gas motors, and 105 miles by horses. Most of the last were in London, and practically the whole of the cable lines in Edinburgh. The horse lines will soon all disappear. The Edinburgh cable lines will probably remain until the local prejudice against overhead wires has been overcome in its last remaining stronghold.

In our modern track, with British standard section rails of 95 lb. or 100 lb. per yard, concrete foundation, rails anchored down both at joints and intermediately, heavy fish-plates or welded joints, we can show work unsurpassed in the world. The great difficulty yet to be surmounted is rail corrugation. We have attained some fair success with an apparatus designed and constructed in our own shops, but I cannot claim that this has proved to be more than an amelioration of the evil. I give here details of the most recent form of permanent way construction on the London United. The foundation is a bed of Portland cement concrete not less than six inches in depth, in which are embedded cross sleepers of old girder rail inverted and bolted solidly to the girder track rails. These sleepers are placed at intervals of nine feet and extend for nine inches outside the gauge line. In addition to the fish-plates, each joint is provided with a girder sole plate consisting of a half-inch plate 10 inches by 20 inches, riveted to a 24-inch length of six-inch girder joist, which is embedded in the concrete. This girder sole plate is bolted to the flanges of the running rail, and forms a very solid and effective support. The result of our experience with this arrangement has been entirely satisfactory. On all extensions constructed during the past three years we have used the rails of the British standard No. 3 size and specification, having a weight of 100 lb. per lineal yard straight track with a depth of 6½ inches and a width of base of seven inches. Practically the whole of our tramway area is paved with Australian Jarra blocks nine inches long, three inches wide, and 4½ inches deep, and close jointed, laid on a floating of sand and Portland cement. All points and crossings are of manganese steel. The cost of construction per mile of double track amounts to £13,000.

Speaking of British tramways generally, I see no reason why they should not enjoy an indefinite period of financial prosperity, skilfully managed, and conservatively financed. There are three points that handicap us in comparison with other countries:—(1) Our tramway cars are not permitted to travel fast enough, the average speed being less than 10 miles an hour. (2) The double-deck tramway car in general use causes much delay, particularly at stopping points. The adoption of this type of car is consequent upon the regulation enforced by the authorities that no car shall be licensed to carry any passenger for whom a seat is not provided. (3) Traffic could be handled more successfully on special occasions were the present licensing restrictions regarding passengers removed or amended. It is undoubtedly the fact that there is no other country in the world where such onerous conditions are imposed upon the operation of electric tramways. In Tokyo, with an electric tramway mileage approximating to that of the London United, 1,000 cars a day are run at an average speed of 20 miles an hour, and the passengers carried number some 300 millions a year, or nearly six times the number carried over the lines of the London United.

THE UNITED STATES.

In America, the growth of electric tramways has been amazing, to a degree impossible in an older and more conservative country. The reasons may be summed up as follows:—Bad roads, cheap and easy grants of franchises and concessions for long or indefinite periods, lack of legislative checks on cheap

Digitized by Google

(and sometimes, at first, crude) forms of construction, alertness of the people to grasp new ideas and opportunities, a general desire for rapid transit, the force-pump of enormous manufacturing interests, the activity and insistence of promoters and speculators, and the political doctrine of individual freedom and equality which allowed everybody to go ahead so long as it was not shown that he was unduly and unfairly injuring his neighbours. Much of the work, of course, had to be done over again, and a better permanent way, better overhead construction, and better power stations provided. Cross sleepers were adhered to, but supplemented by concrete cement instead of stone ballast. In large towns the ancient "step and tee" rail was gradually abandoned in favour of the heavy steel grooved girder rail, and attention was at length paid to the maintenance of the paving approximately level with the track rails. Ornamental steel poles have been widely used in conjunction with good rail bonding and return feeders. Series-parallel control solved the motor difficulty before electric traction development began in this country.

In the early 'nineties nearly every town in the United States with a population of over 10,000 had its electric tramway, and then the construction of inter-urban electric lines feverishly began, partly on roads and partly on private land. In default of restrictions on obtaining franchises, competition with steam railways led to the protective electrification of many of the latter in and near the large towns, but with the railway part of the subject I do not propose to deal. The use of single-deck box cars has been maintained all along, the public finding top seats too hot in summer and too cold in winter, but the cars are largely convertible from close to open by letting down or pushing up all the windows. Strap-hanging is popular, and regarded almost as an institution, there being practically no restriction in the number of passengers carried on any car at one time. Speeds are higher than with us and accidents possibly more numerous. The fare indicator system instead of the bell punch and ticket system is still in use—on inter-urban lines, where there are differential fares in proportion to distance, tickets are necessarily used, but for town lines with the uniform five-cent fare for any distance the indicator remains.

There is little prospect of tramways being worked by municipalities in America. In New York the city authorities have constructed the whole of the latest underground electric railways and then leased the line to the operating company. The people who have anything to lose have a wholesome distrust of local authorities, and too often there seems to have been ample cause for it.

The electric conduit system was first developed on a considerable scale in Washington, where a long line was opened in 1896. A good deal of trouble was experienced with experimental lines of the sort before this date, but the experiments well established the best form of construction. It should be clearly understood that the only reason why the conduit system is employed in New York and Washington is that overhead wires for any purpose whatever are prohibited by the Legislature. In Chicago, San Francisco, and elsewhere, the overhead trolley has been largely substituted for the cable system. In the latter city the change was hastened by the destruction of the tramway system in the great earthquake. A considerable proportion of the American tramways are less prosperous financially than ours, but, so far as engineering and traffic management are concerned, the present-day American administrator deserves unbounded praise for his enterprise and almost consuming energy, and the various departments appear to be most elaborately and efficiently organised.

I quote some figures published in the *Street Railway Journal* of New York, in September last. They represent the state of matters at the end of 1906, and include all street railways and all electric elevated and electric inter-urban railways. The number of companies was 1,164, and the total length of single track of electric railways was 36,212 miles—nearly ten times the single-track mileage of tramways in the United Kingdom. The figure for the preceding year was 32,517 miles of track. The number of motor-cars was 66,206, against 63,391 in the previous year; and of trailer cars 15,442, against 13,059. Adding a track mileage of 719 for cable, steam, and horse lines, with 3,084 cars, we get for all kinds of street railways, and for elevated and inter-urban electric railways, a total track mileage of 36,932, with 84,732 cars. The latter figure compares with 11,746 cars in the United Kingdom; but to make a just comparison the mileage and cars of electric railways in this country should be added to the Board of Trade figures. The single track mileage of electric railways in this country at present, as distinguished from electric tramways and electric light railways, is 353, and the number of cars in stock is 2,074. Adding these to the Board of Trade tramway and light railway figures, we get a total of 4,191 miles of track and 13,820 cars.

The total capital liabilities of the United States street railway companies and elevated and inter-urban electric railway companies is returned at $3,765,317,875, or over £750,000,000—equal to fully £20,000 per mile of single track.

British Colonies.

To Canada I have not turned special attention. The style of construction is similar to that in the United States, but the population is relatively small, and the number of undertakings in 1906 was only 48. Electric power is almost exclusively used. The total length of lines, measured as single track, was 1,150 miles, and growth is rapid, as in the preceding year the length was only 956 miles. The number of cars was 2,920, against 2,697. The capital liabilities were $82,155,671.

Australia has no extensive systems of mechanical tramways outside Melbourne and Sydney. The Melbourne cable tramways, which are very successful, are worked by a company under arrangements with a joint board of municipalities. The Sydney tramways, mostly electric, are worked by a department of the State, and the voluminous reports issued are well known. Tramways in other towns are electric, except in Adelaide, where a large horse system has been taken over by the local authorities, and is now being extended and electrified. In New Zealand there are only a few tramway systems, mostly electric; they await further population in order to develop, but, in proportion to the existing population, they do a remarkably large business. The construction and equipment, both in Australia and New Zealand, are similar to those in this country. The same remarks apply to South African tramways, which, unfortunately, are suffering from the trade depression there.

I was much struck during my recent journey with the development of electric tramways in Tokyo, Yokohama, Shanghai, Hong-Kong, Singapore, Colombo, &c. These follow Western models; indeed, most of them have been built and equipped by British engineers. In Japan, however, they are run by native officials; but in China Europeans are in administrative command, as in those towns in India where tramways have been installed. The natives take well to the innovation. The cars are usually divided into two classes. The main obstacle to greater development in eastern cities is the narrowness of the streets. This is particularly noticeable in Tokyo, the capital of Japan. The city is a network of electric tramways, either in operation or proposed, though there are several important main arteries of traffic too narrow to admit of even a single line of rails. The greatest possible impetus is given to the promotion of important lines of electric railways extending from Tokyo and connecting with the large, and in some cases far distant, provincial business centres.

Europe.

On the Continent of Europe electric traction secured early recognition, and it was in Budapest that the first extensive conduit system was constructed. It was designed by Siemens and Halske, and the conduit is under one of the track rails, which has a slot for the current collector instead of a groove. Germany was the scene of many experiments with the electric accumulator in towns where the local authorities were slow to allow the use of overhead wires. These trials were not financial successes, though they hardly appear to have been so disastrous as the experiments in this country. Speaking of purely street lines, the greatest developments are in Berlin, in the hands of the Great Berlin Tramway Co., and in Paris under a number of companies. There has been a bewildering variety of systems, but the overhead trolley rules in most places. Track construction has also presented many varieties, but is gradually conforming to standards like our own. It is difficult to get details in regard to installations in a number of countries, but an effective bond of association is provided by the Permanent International Tramways Union, of which practically every tramway company of importance on the Continent is a member.

I have spoken at some length on the adaptability and elasticity of the overhead trolley system, and, though time precludes my dealing with the important electric tramway developments in Russia, I may perhaps refer to an extraordinary little trolley line in that country which is equipped afresh and put into operation for five months of every year over the River Neva, at St. Petersburg. Climatic conditions are, in some other lands, comparatively even, though it is difficult for us to conceive it possible; and the company are able to anticipate with certainty the freezing of the river. Sleepers and rails are laid down, standards put up, trolley wires run across, and a system one and a half route miles in extent is running electric cars over the delta of the river, until the approach of the warm season warns this enterprising company to dismantle the line until the following winter.

Conclusion.

Electricity utilised for the purposes of traction has resulted in enormous and world-wide benefits, and we may confidently anticipate further great development in the future. Too often in this country have we lagged behind in the race with other countries, not from any backwardness in our capitalists, inferiority in our engineers, or lack of enterprise in our business men, but because we have been bound by legislative restrictions and innate conservatism. I said in the Paper I read before the Royal Society of Arts in 1902, "Senseless and archaic obstacles to legislation should be ruthlessly set aside, and all personal and vested interests should be made to give way before the clamant cry of London."

My hope is that the public, having tasted the sweets of rapid transit in urban streets, and the pleasures of penetrating cheaply and quickly to such lovely resorts as can now be reached

Digitized by Google

from London and other large cities, will give Parliament "Moving Orders" to substitute for "Standing Orders" that throttle business, inducing class or special legislation and conferring upon certain vested interests a monopoly of roads which should be equally at the service of all.

After Sir Clifton Robinson had delivered his address, the Duke of Argyll proposed a vote of thanks to him, and said that he was obliged to plead guilty not only to being a member of the "inert monster" to which Sir Clifton had referred, but also to having been on some of the Committees which have had to deal with electric traction. He had, however, on most occasions sided with the civil engineer who had been poking up this "inert monster." The monster would, however, still have to keep its hand upon some of these enterprising civil engineers, who were people of such ambition that they had sometimes to be restrained. Sir Clifton had also told them that the Houses of Parliament were senseless and archaic, and he presumed that he meant the former epithet to apply to the lower House, and the second one to the House of Lords.

After a short adjournment, the meeting resumed under the chairmanship of Sir Clifton Robinson, and discussed a Paper by Mr. Alfred Gibbings on "Tramway Rail Joints."

TRAMWAY RAIL JOINTS.

By ALFRED H. GIBBINGS.

The modern permanent way in this country has become almost of standard construction, owing to the great similarity of the conditions under which tramways have been inaugurated. These conditions have their origin in the requirements of Acts of Parliament, the Local Government Board, the Board of Trade, and Local Authorities. The track is usually formed by laying girder rails directly on a bed of concrete, but there are some exceptions, notably at Sheffield and Hull. At Sheffield several experiments have been, and are being, tried with various forms of wooden sleepers laid longitudinally under the rails, to which the rails are anchored down by bolts and plates, and this sleeper forms a good support for the joints. It appears, however, too soon to say whether this method, in addition to forming a cushion for the rail, also results in a satisfactory joint. It would seem that any initial irregularity in the rail ends forming the joint would ultimately result in the well-known knocking, and would produce holes where the wheels jumped forward. At Glasgow, during the last three years, heavy cross timber sleepers have been adopted on all extensions and renewals of track. For the purpose of this Paper, however, the ordinary concrete track will be assumed.

The rails now employed with the electric trolley street railways are of the grooved girder form. Considerable divergence exists, however, in design, width of groove, depth, and composition of metal. In most of the principal towns the rail weighs from 90 to 105 lb. per yard, according to the section. Figs. 1 and 2

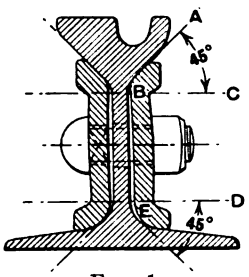

FIG. 1.

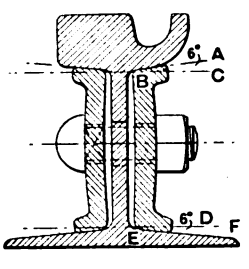

FIG. 2.

illustrate forms of grooved girder rail in section, Fig. 1 being a type employed up to fifteen years ago, and Fig. 2 being the type used recently by the writer on two large tramway undertakings. The illustrations have been chosen to indicate the difference in the angles under the head and over the flange of the two types. With the inauguration of steam and electric street railway systems, deficiencies of jointings were quickly apparent, and all the trouble with bonds and fishplates, through pounding, began to be experienced. The effect of this pounding was, of course, the re-design of the rail section and fishplates, and the introduction of special devices to prevent the destruction of the rail at the joint, and to obviate the damage to rolling stock and the annoyance to passengers in the cars. Many hundreds of patents have been taken out during the last thirty years, improvements in rail joints and fishplates.

FISHPLATES.

In explanation of Fig. 1, it must be pointed out that the angle which the bearing portion of the fishplate makes with the web of the rail is 45°, and with the flange of the rail the angle is 45°. In the modern section (Fig. 2) these angles are respectively 6°, that is, just sufficiently out of the parallel to admit of properly and efficiently tightening up.

The simplest method of comparing the lateral thrust upon the fishplates due to the various fishing angles would seem to be to consider the angles A B C, D E F, as wedges tending to force the fishplates apart, the driving action on the wedges being produced by the weight on the car wheel, when passing over the joint.

If we assume that the fishplates are perfectly rigid, and thereby neglect the effect of the rail web, the formula for the resultant of the top and bottom wedging action becomes :—

$$x = \frac{y}{\text{Tan}\,(a_1 + \phi) + \text{Tan}\,(a_2 + \phi)} + \frac{y}{\text{Tan}\,(b_1 + \phi) + \text{Tan}\,(b_2 + \phi)}$$

where

x = Tension on bolts due to wedging action.
y = Weight on car wheel.
$a_1\ a_2\ b_1\ b_2$ = Angles from centre line of web.
ϕ = Angle of repose (approx. 10°).

Assuming the weight on the car to be 3 tons,

then, for Fig. 1, $x = 2\left(\frac{6720}{2\ \text{Tan}\ 55^\circ}\right) = 4704$ lbs.,

while for Fig. 2, $x = 2\left(\frac{6720}{2\ \text{Tan}\ 94^\circ}\right) = 468$ lbs.

Hence the strain on the bolts in the first case is more than ten times that in the second case. As it is absolutely essential that a tramway joint, when once screwed up, should remain tight, it follows that the rail should be so designed as to relieve the bolts as far as possible of any tensional efforts tending to loosen the fishplates. The formula by no means represents the total strain on the fishplates, but it serves to demonstrate the effect of the varying angles. The difference is really more in practice, for the stress is in the nature of repeated shocks. The angle of slip has also to be considered, which is approximately 10°, so that the angles of the fishplates should not appreciably exceed this.

If the modern type of fishplate for tramway track is compared with the fishplates on steam railways, which fishplates are much lighter and smaller, it may seem strange that no appreciable or serious trouble occurs in this latter case. The reason, of course, is that there is no difficulty in keeping the railway fishplates quite tight, as they are above the surface of the ground, and they receive constant attention.

Experience proves that in all cases joints have a tendency to become loose and "spring" through the continual passing over of the cars, and, however slight this springing may be at first, it is rapidly increased by every car which passes over it. Hence, when the joint is badly worn, it appears that the only remedy is to cut out and renew either the joint or the concrete beneath it, or both. This becomes a very expensive operation, and necessitates removal of setts and paving. It seems to follow, therefore, as a natural deduction from the foregoing remarks that fishplates should not be required to take a vertical thrust.

The function of fishplates should be confined to jointing the web, and the vertical thrust should be taken by some other means.

In order that the latest practical experience might be brought to bear upon this subject, the writer submitted a list of inquiries to several tramway managers, and they very kindly responded to the request for information. Their replies are embodied in the following paragraphs, and they record wide and diverse experiences.

SOLE PLATES.

The original and simplest method of taking the vertical thrust at the joint was by means of sole plates and fishplates. Sole plates are now in use at Hull and Darwen. In the case of Hull the rail ends are cut to an angle of 45° in plan, and the rails are laid on continuous-creosoted sleepers. At Darwen they are apparently being discarded in favour of other types. In neither case has any account been kept of the cost of renewals.

WELDED JOINTS.

The principal welds are the "Falk," the "Thermit," and the electric. One or other of these welds is in use in many towns, including Glasgow, Leeds, Southampton, Nottingham, Liverpool, Brighton, Darwen, and West Ham. The replies from Brighton and Darwen are both favourable to the welded joint, but it does not appear that welds have been extensively used in those towns.* In addition to these places, there are, of course, many others where the welded joint has been adopted.

The advantages which are claimed for the welded joint may be summed up in the statement that it should constitute a continuous rail, both as regards wear and tear and electrical conductivity. There can be no doubt that when two rail-ends are thus fastened together with a close joint, the result will appear theoretically and practically perfect. As a matter of fact, however, the rail-ends in some portion of the rail and rail-head always remain severed, and this occurs principally near the running surface or point where the real wear takes place. All three processes also tend to alter the temper and nature of the rail-ends, and so produce a new fault while remedying an old one.

* These statements were controverted in Mr. Stutz's remarks in the discussion (see p. 105).

Digitized by Google

The opinion at Glasgow is that the welded joint is the most satisfactory from every point of view, except in the case of renewals; at Leeds and Southampton a similar opinion is expressed, but at West Ham no comment is made. It must be noted that in each of these instances the experience with these joints has been only for about three years.

At Nottingham the City Surveyor puts the life of a welded joint at about three years, as at the end of that time fractures begin to occur and renewals are necessary.* It seems to be the practice there, when a renewal is required, to cut out the weld for a distance of about 18 in. on each side of the joint, and then to insert a new piece of rail, thus getting two joints in place of one. In Liverpool the same difficulty of fractures has arisen.† The foregoing remarks apply to new track welds, and it seems to be the general experience that the process is not well adapted to old track. The important question, therefore, with regard to this method is what is going to be the result in a few years when large renewals become imperative.

One of the striking features of the replies received from tramway engineers is the statement in nearly every case that no separate accounts are kept of the cost of renewals or repairs to joints.

ANCHORS.

The more prominent types of anchors in use in this country are illustrated below: The "Winby" anchor (Fig. 3), the "Kirkland" anchor chair (Fig. 4), the "Bull Dog" (Ames-Crosta) anchor (Fig. 5), the "Positive" (Walker & Grant) rail anchor (Fig. 6), and the "Cooper" anchor (Fig. 7).

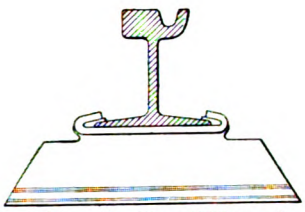

FIG. 3.—THE "WINBY" ANCHOR.

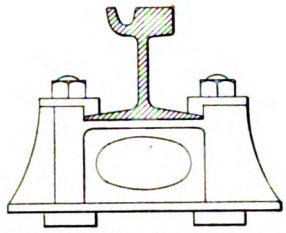

FIG. 4.—THE "KIRKLAND" ANCHOR CHAIR.

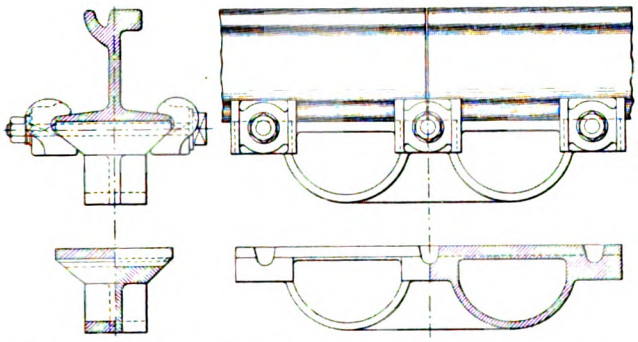

FIG. 5.—THE "BULL DOG" ANCHOR (AMES-CROSTA).

The anchor joint, in one form or another, appears to have appealed to a great number of engineers, and may be found in use on the majority of tramway undertakings. Anchors are preferred or are used in Burnley, Huddersfield, Bournemouth, Wolverhampton, Birmingham, and Darwen. The writer has also put them down throughout a 25-mile system of tramways.

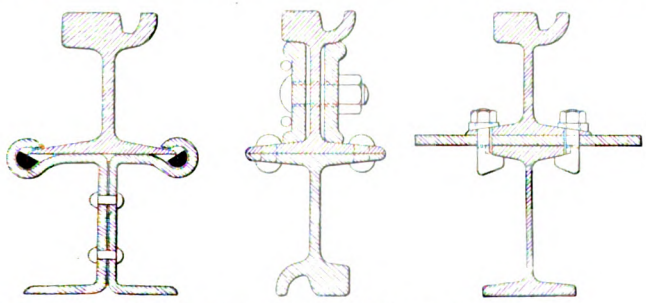

FIG. 6.—THE "POSITIVE" RAIL ANCHOR (WALKER & GRANT).

FIG. 7.—THE "COOPER" RAIL ANCHOR.

FIG. 8.

The Cooper anchor (Fig. 7), or piece of inverted rail, may be fastened to the rail, either by bolts or rivets. Bolts are hardly likely to be satisfactory, as, like fishplate bolts, they tend to work loose.

In all cases of anchors at joints the ordinary type of fishplate is used, the function of the anchor being merely to prevent springing of the rail-ends.

The success of this method of jointing depends absolutely on the stability of the concrete in which the anchor is buried, the nature of the soil beneath the concrete, and getting a true alignment on the running surface, without grinding. From the insufficiency of one or both of these conditions many anchors have failed.

On the London County Council tramways the joint adopted, known as the girder joint, is constructed as follows (Fig. 8),* viz., a piece of steel H joist, 30 in. long by 5 in. wide and 8 in. deep, weighing 30 lb. per foot, and a steel plate 30 in. long by 12 in. wide by ½ in. thick, are fastened to the rail by 2½ in. by ¾ in. hook bolts. The attachment is made by the hooks of the bolts fitting into slots made in the top of the flange of the joist and fastened through holes in the plate and bottom flange of the rail, and the nuts are screwed down to a bevel washer. The bolts are made of mild steel, and are threaded for a length of 1½ in. from the nut.

The experience at Burnley is interesting, and tends to bear out entirely the dependence on the condition of the soil and concrete. It is there claimed to maintain a good joint, but that hammering develops after two or three years, when the rail has to be ground. It is further stated to be bad for the rolling stock, and that rigid foundations and hammered joints break the car axles. With regard to anchor joints generally, it is found here again that their application has been confined to new track work. The expense of excavation and fixing to old track is too great, to say nothing of the problematical satisfactoriness. It would also involve grinding down the surface of the rail, and that, in addition to being expensive, is never satisfactory.

COMBINATIONS.

A combination joint consists of a device in which an attempt is made to distribute the forces and counteract the effects of the hammering and pounding. Several types (illustrated below) have already been tried with considerable success.

Booth's rail joint differs from the "Continuous" rail joint in the separate soleplate which extends entirely under the flange. It

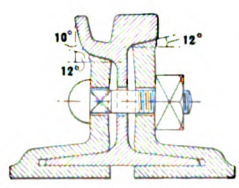

FIG. 9.—THE "CONTINUOUS" RAIL JOINT.

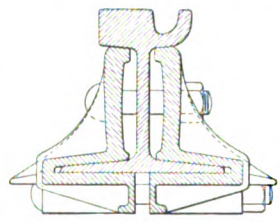

FIG. 10.—THE "ATLAS" RAIL JOINT.

is difficult to see what different effect in practice there can be between the two types, provided that the fit to the rail section is equally good in both cases. It is just this qualification which is likely to constitute the chief difficulty and obstacle in practical application. An examination of the section (Fig. 11) will indicate more clearly than any written description, the absolutely accurate fit which is required. In this respect it seems that Booth's joint would have the better chance, as the fishplates can be bolted into place before the soleplate is rivetted on.

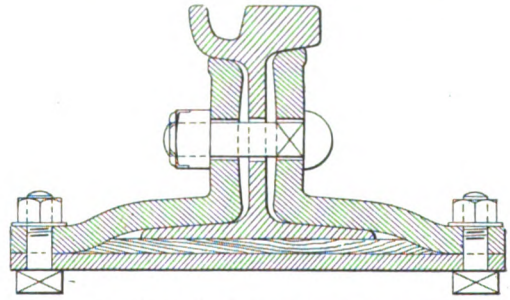

FIG. 11.—BOOTH'S CONTINUOUS RAIL JOINT.

On the Cavehill and Whitewell tramways "Positive" rail anchors are fixed at each end of the "Continuous" rail joint. It would be interesting to know what is the cost for joints and anchors on that line per mile of single track, but, apart from that, the solidity of the joint, if laid on concrete, must be rather more than the rest of the rail.

Reverting to the question of the fitting of these joints, no absolutely accurate fit between the head and flange can be assured, because in practice no two rail-ends which are brought together

* This statement is corrected in the letter which Mr. Gibbings read before the Paper was discussed (see p. 105).

† Mr. Stutz said, in the discussion, that this was incorrect.

* Mr. Welling corrects this statement in the discussion (see p. 106).

Digitized by Google

to form a joint are rolled exactly to the same section. It is this slight difference, either in depth of rail, thickness of head, or variation in the dimension between the under side of the head and the top of the flange, which gives rise to the trouble of knocking and hammered joints. The usual design of fishplates, whether uncombined or in combination with soleplates or anchors, keeps the under sides of the head of the rail in alignment (where it is obvious alignment is not required) and not the top or running surface. Hence this prevents a true surface alignment in the majority of cases.

With regard to the "Dicker" joint (Fig. 12), these have been put down in several towns, and particular reference to them is made by Preston and Darlington. Some experience of these joints has been obtained at Liverpool, and also on the Tooting lines of the London County Council.

Mr. Alexander Millar, in his Paper on "The Electrical Reconstruction of the South London Tramways on the Conduit System" (Inst. Civil Engineers, January 12th, 1904), remarks that "the ordinary track rails are laid at all parts of the line, except the sharp curves, junctions, and crossings, where a slightly heavier rail is used. They weigh 102 lb. per yard, and have a tensile strength of 42 to 49 tons per square inch. The joint formed by cutting a sleeve ¾-in. wide out of the track-rail head for a short distance at the rail-ends, and replacing the metal cut away by a deep fishplate, the upper surface of which is flush with the rail-head, breaks the rail-joint, and provides a continuous-running surface for the car-wheels. This form of joint has been extensively used of late years in tramway undertakings in this country, and the author's experience of it on this and other lines has been favourable. Care must be taken in securing the correct height of the fishplate, and in gauging the extent of cut in the rail-head. A 15° fishing-angle is used, and it will be observed that at the bottom the fishing-angle does not extend to the tip of the flange, as, had it done so, the amount of metal of the flange would have been needlessly increased. At sharp curves a slightly heavier rail, weighing 104 lb. per yard, with wider groove and broader lip, has been employed. It was considered safer to have longer fishplates here, owing to the greater liability of rail-joints to work loose on sharp curves and at crossings, &c."

Mr. Rider, in a discussion on Mr. Alexander Millar's Paper, says:—"The joint used was called the Dicker joint," shown in Fig. 12. "Part of the head of the track-rail was cut away, and one of the fishplates was carried up to the head of the rail, so as to form a running-surface for the car-wheel. That particular fishplate had absolutely nothing to do with taking any

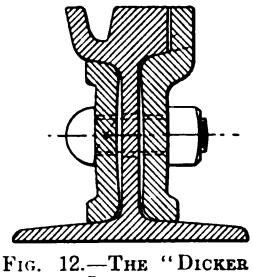

FIG. 12.—THE "DICKER" JOINT.

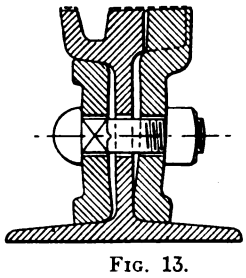

FIG. 13.

of the weight of the rail, because the whole of the fishplate was carried up through the head of the rail, and it was only a four-hole fishplate about 2 ft. long. One of the results of that type of joint was that the fishplate which, under normal conditions was tightened up by the bolts, and lay against the head of the rail, was now showing signs of leaving the rail at the top. It was not so noticeable on the surface, as apparently the hammering effect of the wheels burred the edges of the rail and the fishplates. It was caused by the bolts giving, and the effect was something like what is illustrated in Fig. 13. If those fishplates had been extended under the head of the rail, with an ordinary fishplate on the other side, the joint would have been better. On the new lines that type of fishplate had been given up, and the ordinary pattern had been adopted on either side of the web, an anchor plate, consisting of an inverted piece of rail rivetted to the bottom flange, being put under the joint. Such a joint was quite rigid, but even with it a difficulty had arisen. On account of the variations in the rolling of the rails, it was not possible to get lengths taken indiscriminately which were exactly the same depth. When the soleplate was put under the joints and rivetted to the flanges the bottoms of the adjacent rail-ends were brought exactly into line; consequently, the least variation in the depths of the two rails, due to difference in rolling, showed itself at the head, and was enough to start a slight hammering action under the traffic, which became worse. The only remedy was to grind the heads perfectly flat with a portable grinding-tool after the joint had been made and the soleplate put on; that gave a perfectly good running joint."

It will be observed from the foregoing extracts that the fishing angle on the "Dicker" joints is here stated to be 15° or 5° over the angle of slip. This may account to some extent for the trouble mentioned by Mr. Rider, as he distinctly refers to the giving of the bolts.

FORGED RAIL-ENDS.

Several years ago an attempt was made to forge out the fishplate and rail-end in one, by means of a portable hydraulic press and furnace. The rail-end was formed in such a manner that the joint faces were at an angle of about 30° with the rail edge. The idea was never successful in practice for several reasons. First, the cost was prohibitive; and, secondly, the rails were much shortened in the process. The re-heating also had the effect of softening and injuriously affecting the steel.

ADJUSTABLE JOINT.

This device differs in almost every particular from those which have been described herein. It consists of two plates of rolled mild steel, one being superimposed on the other. In the upper plate are two steel screws, having gas threads, and on each screw is a combined protection and lock nut. The apparatus is shown in cross-section, with the rail, in Fig. 14. The arrangement is

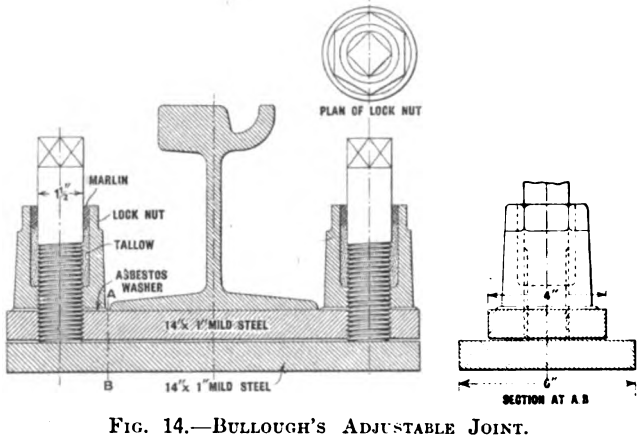

FIG. 14.—BULLOUGH'S ADJUSTABLE JOINT.

simple, and by slightly turning the screws, the upper plate is raised, thereby raising the rail-ends and "supporting" the joint. Any subsequent depression due to the rolling load or any other cause is readily adjusted by the use of a box-spanner without any disturbance of the paving.

In the case of old track or repairs the disturbance of the paving setts in fixing is reduced to a minimum. The heads of the rails are raised and maintained at one level, thereby giving a perfectly true joint, thus preventing the lifting of the setts or paving. Where the rail-ends differ slightly in depth, the fault can be remedied by placing a "skim" or liner of the required thickness on the supporting plate under the flange. This liner must be placed close to the end of the rail, so as to place the weight on the centre of the bolt. It will be observed that this joint-support provides for the natural and inevitable expansion and contraction of the rails.

In order to obtain the absolute and correct adjustment of the support when first put in, and after the concrete has set, several cars should be allowed to pass over the joint, and observation made of any slight knock or spring which may exist; the screws are then given a slight turn, say, a quarter turn at a time, until it is certain that no sound whatever can be detected as the cars pass over. The lock nuts are then tightened, and the joint is complete. The lock nuts are hollow, and the space around the screws is filled in with melted tallow. These supports have been put down on several systems during the last three years.

An interesting "mechanically-locked" joint, illustrated below, was exhibited. In it an eccentric bolt is employed for the fish-

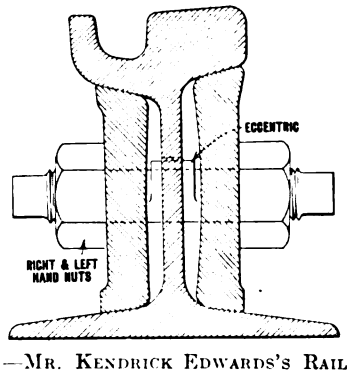

FIG. 15.—MR. KENDRICK EDWARDS'S RAIL JOINT.

plate instead of a circular one, so that the bolt may be turned by a forked spanner to bring the rail-ends tight against one another before the nuts are screwed up. The threads of the bolt

Digitized by Google

and nuts are right- and left-handed, and it is claimed that any tendency for the rails to come apart results in a tightening of the nuts. The joint is the invention of Mr. Kendrick Edwards, of Belfast.

Mr. Gibbing's Paper was taken as read, but before the discussion was commenced, he read the following letter which he had received from Mr. Arthur Brown, City Engineer of Nottingham.

DEAR SIR,—The Thermit Co., Ltd., have sent me a copy of a Paper to be read by you before the Tramways and Light Railways Association on Thursday, the 9th inst., and I enclose for your information a copy of the correspondence which has taken place between the Thermit Co. and myself. Confusion appears to have arisen regarding welding on *new* track and welding on *old* track. I have a quantity of Thermit joints which have been in use over four years, and which are now quite perfect. I believe that the Thermit joint makes the best joint, providing the work can be done in suitable weather. As you will see from the letter I have written to the Thermit Co., I should very strongly object to doing any Thermit welding in very hot weather, as if this is done when the air is at a high temperature breakages are bound to occur.

(*Letter from Mr. Arthur Brown to the Thermit Co., Ltd.*)

GENTLEMEN,—I am in receipt of your letter of the 1st inst., enclosing copy of the transactions of the Tramways and Light Railways Association.

I cannot trace having given any information to Mr. Gibbings as regards my experience of Thermit welding. The paragraph would be correct if it read, "The Nottingham City Engineer puts the life of the welded joint at about three years, as at the end of that time fractures begin to occur and reconstruction of the joint becomes necessary. The practice is to cut out on either side of the weld for a distance of about 5 ft. and put in a closure 10 ft. long. The foregoing remarks apply to the welding of *old* track." This is where I think Mr. Gibbings has made a mistake: he has evidently obtained his information from some other source and not directly from me, and has confused work on new track with work on *old* track.

I should certainly never again weld joints on old track. We did about a dozen of these and over 50 per cent. broke. I have, however, still a firm belief that the Thermit weld for new track work makes the best joint, but I must qualify this by saying that I should never again lay down a track with Thermit welded joints in very hot weather. If it was absolutely necessary for the work to be done in hot weather I should put down ordinary fishplate joints with long H iron anchors under the joint.

Mr. Gibbings also explained that the information upon which the Paper was based was obtained two years ago, and that therefore some slight inaccuracies were inevitable.

DISCUSSION.

Mr. J. R. SALTER (Lancashire United Tramways, Ltd.) pointed out that Mr. Gibbings had said nothing in his Paper upon the very consideration which made the subject of rail joints of such importance, viz., the question of paving. He contended that rigidity in the construction of tramways and in the points was required for the purpose of maintaining the level of the paving to the level of the rails, and that, were it not for this fact, the more we could approximate to the flexible or yielding track construction of our main-line steam railways, the better would it be for smooth running. He pointed out that on his own system he had seven miles of track laid on longitudinal wooden sleepers, and with no concrete, this method of construction having been necessary on account of the tramway being over a 56 in. water main, which burst throughout its length on an average 250 times a year. He also directed attention to the method of construction adopted in Moscow, where no concrete was used, and in this instance also smooth running was obtained; but, of course, the paving suffered and great expense was involved in maintaining it. In Moscow the question of paving was not so serious, as for seven months in the year the roads were covered with snow, the ordinary vehicular traffic being in the nature of sleighs. He recollected a remark made by the Hon. Arthur Stanley, M.P., to him, which was very much to the point, namely, that the present system of constructing tramways was "right in the abstract but wrong in the concrete." In referring to the adjustable joint illustrated in Fig. 14 of Mr. Gibbings' Paper, Mr. Salter pointed out that water would accumulate in the gap between the two soleplates, and, in consequence, the paving around the joint would soon give way. He next criticised the empirical mathematical formula given in the commencement of Mr. Gibbings' Paper, and stated in strong terms that this formula was absolutely inapplicable to the question under consideration, and was based entirely upon a wrong supposition. He contended that there was no wedging action with fishplates, and that it was impossible in considering the action of fishplates to eliminate the web of the rail. The action of the fishplate was an oscillatory one in a vertical direction round the joint as a centre, and that this was so was evident from the fact that it was quite unnecessary for the fishplate to come up under the head or lip of the rail at all. The reason the fishplate was extended to fit closely between the head and lip and bottom flanges of the rails was to overcome the oscillation. With all these new proposals, an "angle of repose" was certainly desirable, but not of the sort that need be designated by ϕ or any other Greek character.

Mr. J. B. HAMILTON (Leeds City Tramways) suggested that it might have been good for the writer of the Paper to have brought it up to date, as, particularly in its remarks about welding, it was obviously quite inaccurate. The remarks with regard to the short life of welded joints must be a clerical error; they could not apply to new track. It was unfortunate that a more careful examination had not been made into the general experience and results obtained from the use of thermit as a welding process. Under the heading of anchors, the writer had referred to five different kinds, all of which were patented, but he had overlooked the very best arrangement of all, which had a further advantage of not being patented, and that was the use of old rails for this purpose. The adoption of anchors for the purpose of keeping rails steady was of the first importance in tramway construction. Experience showed that rails laid on a rigid foundation, such as was used in all streets which are open for general traffic, cannot be maintained in a satisfactory condition to keep the setts firm and maintenance costs low without efficient anchoring. In tramway undertakings, therefore, which have been worked, as in the case of Leeds, for ten or twelve years by electric traction, it had been found absolutely necessary to anchor all rails on new construction or where renewals had been carried out. The standard type of construction adopted in Leeds for the last six years had been to anchor at close intervals, particularly at the rail joints, to weld all joints by the thermit process, and to float them with a strong composition of concrete well up over the base of the rail. Many miles of track which was only half worn out had had to be taken out in Leeds and throughout the country because they were not anchored and welded when put down, and it was found impossible, hammering having set in at the joints, to maintain them in a rigid position.

Mr. A. N. BANISTER (Norwich Electric Tramways Co.) said that Norwich and Coventry were the first two towns in England in which experience had been gained with the Falk joint. They had about 4,500 to 5,000 joints in Norwich; their experience extended over eight years, and had been very satisfactory. Only one joint had broken during that time. Hammered joints were few, and, in fact, it was difficult to find a joint at all. Four years ago, however, they had adopted the Thermit joint, as they found it considerably more economical for renewals and repairs, for the cost of each joint was no more if made one at a time, than if made in batches of fifty or more. With the Falk process, on the other hand, unless there could be a run of 20 or 30 joints at one time, they were very expensive to make. He did not approve of any of the mechanical joints which required accurate fitting, as it was difficult to get the ordinary platelayer to do work of this character efficiently. He believed it was claimed for the joint shown in Fig. 14 that in the event of any settlement, the joint could be raised by means of the screws without touching the paving. But directly the screw was tightened up so as to lift the joint, the adjoining paving must be sprung, cracking the joints and allowing water to get in. Also the rail would be sprung from its seat for a greater or less distance from the joint, admitting water under the rail. Once that happened, both joint and paving were bound to work loose. One great advantage of welded joints was the excellent rail return which was obtained. In Norwich the average drop over the whole system was $2\frac{1}{2}$ volts, and they had no boosters or return feeders. The highest drop was on a route about three miles long, with a ten-minute service, on which the drop averaged about five volts.

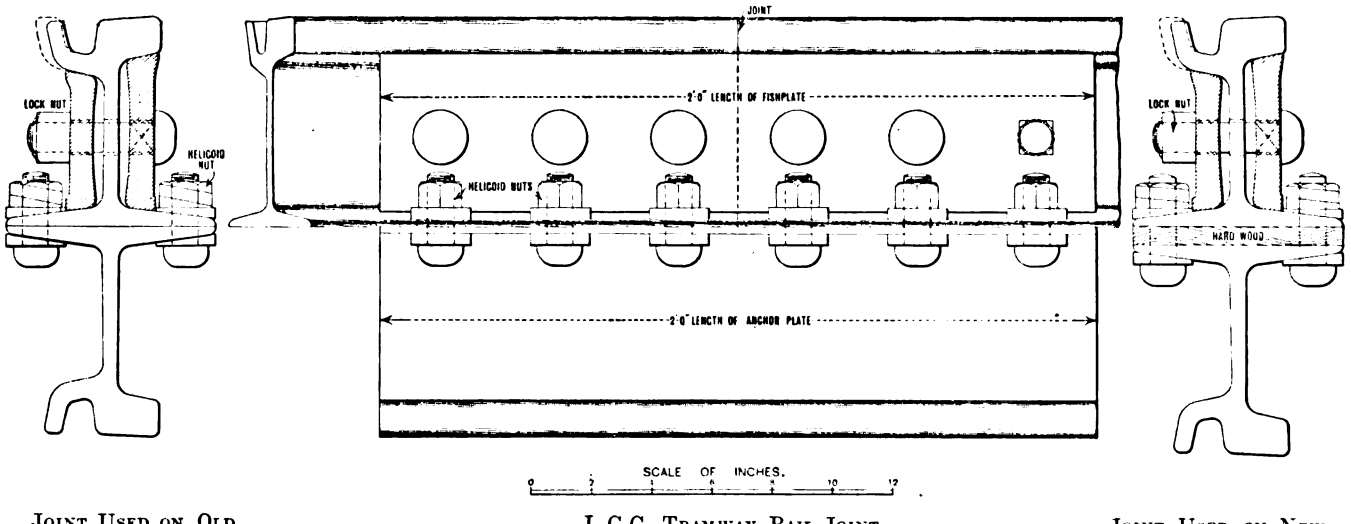
Mr. R. STUTZ (Thermit, Ltd.) said that Mr. Gibbings, in talking about the welded joints, had placed the Falk on the same level with the Thermit and electric welds, but the Falk joint was not a weld; a large quantity of liquid cast iron was poured round the joint, but, although there might be adhesion at points, there was no actual amalgamation. Mr. Gibbings had explained that, by reason of his Paper having been written some time ago, some of the information was not quite up-to-date, and this applied specially to what was said about Thermit welding. He (the speaker) had with him a letter from the Borough Engineer at Darwen, stating that out of a total of $7\frac{1}{4}$ miles of track, six miles had been welded by the Thermit process and had given complete satisfaction. The West Ham system was completed before Thermit welding was thought of by them to any extent, and the few joints made were experimental ones. For Liverpool Mr. Gibbings' information was again incorrect. No joints made by the Thermit Company in Liverpool had given rise to any trouble, nor had there been any fractures. Moreover, the process had been used in a great many other towns since Mr. Gibbings' Paper was written.

Mr. E. BENEDICT, speaking as a railway engineer, and not as a tramway engineer, said that the difficulty with sleepers on tramway routes was, in his opinion, entirely a question of inadequate draining around them. He also hazarded the suggestion that a layer of compressed felt under the rails might prevent the joint from working loose.

Digitized by Google

Mr. H. M. SAYERS said that the chief desideratum was that the rails should be equally rigid or equally elastic at all points. The question of a rigid line as against an elastic line did not really come in when considering the question, but it was differences in the rigidity which promoted the troublesome knocking. Pointing to a specimen of the joint used on the London County Council tramways which was exhibited, he said that a weak point in this was that a large amount of the concrete had to be sacrificed to make room for the anchor which would consequently only be resting on a very thin layer of concrete. He thought that a welded joint was the most promising one, the only thing against it appeared to be that there was a certain softening of the rail on either side of the joint, but apparently this caused no increase in wear. A great advantage of a welded joint was its conductivity, for if copper bonds were used of a greater section than corresponded with 50 per cent. of the conductivity of the rails themselves, they became too expensive, and it was difficult to find room for them under the fish plates.

Mr. JOHN WELLING (Track Superintendent, L.C.C. Tramways) said that rigid foundations were ideal if all bearing surfaces were wide; they prevented destruction of foundations through hammering, but were expensive and almost impracticable to maintain in good condition after repairs and renewals had been made during continuance of service. Elastic foundations, if too elastic, were not good, but a small allowance of give was desirable so as to render repaired joints as good as the original. frequent cause of bad joints, as this difficulty was partly eliminated by filing away the rail surfaces until a level or the same plane is obtained. This, Mr. Welling explained, is now almost universal practice, but its full benefit cannot be maintained long unless the fishing surfaces of the fishplates to the rail are also an absolute fit for each of the rail ends, a result to be only obtained by the "fitting" of each pair of fishplates. The conditions under which hammering joints develop, seeing that an unyielding soleplate and a level surface is easily obtained, seemed, he thought, to point to the varying composition of rails as the chief cause. Many rails, he pointed out, are easily bent, while other rails from the same batch, and possibly made from the same cast, break when being bent under the same conditions; and some again are more easily cut with the cold chisel than others. The welded joint, said Mr. Welling, also hammered after a time. The unequal wear of adjacent rail ends set up a depression on the softer rail (whether the foundation was rigid or elastic), and this became the more accentuated as time passed, and appeared again after repairs had been made. If more care was taken in the mixing of the rail materials, and in the careful and more extensive cropping off of bad and spoilt ends, together with more exactness in the fit of fishplates, defective joints might be very greatly diminished in number. The L.C.C. experience was that bolted joints were as efficient as, and certainly more convenient than rivetted, especially if the bolts had lock nuts embedded in the



JOINT USED ON OLD CONTRACTS.

L.C.C. TRAMWAY RAIL JOINT.

JOINT USED ON NEW CONTRACTS.

This effect might be obtained by bearing rail ends on a thin layer of, say, very hard wood of only sufficient thickness to make it useful and strong enough as a packing or bedding piece, without being so thick as to allow play of the rail ends, owing to the blow of the passing car. Longitudinal sleeper foundations would most probably give too much elasticity for ordinary roads. They were employed in the L.C.C. subway (where there was no wet), but not on the Council's main lines. "Hammering" and "knocking," Mr. Welling continued, result from very minute beginnings of movement in the rails. It was worth considering if there was an even sufficient compression of the rail metal due to the weight of car to cause the slightest depression in the running surface, which would start the hammering. The lateral pressure was also very severe, causing enormous and sometimes sharp vibratory tension on the joint fastenings, and tending to loosen them; and these drawbacks might be avoided or diminished by a thicker and thus stiffer vertical web than the present 7-16 in. or ½ in. for 7 in. rails. The deflection of the usual rail section under the car weight, upon an ill-fitting soleplate would be sufficient to initiate "knocking." Mr. Welling then said that the joint, illustrated in Fig. 8 of the Paper, was not the L.C.C. joint. The figure above shows the actual form employed. The rails weigh 105 lb. per yard, and have fishplates ¾ in. thick and 2 ft. long, weighing 56 lb. per pair. There are six fishbolts per joint, 1 in. diameter, with helicoid locknuts. The soleplates are 2 ft. long, and are of inverted girder rail, fixed by 12 bolts (6 each side), with lock nuts. The whole is embedded in 3 to 1 cement concrete. As to the satisfactoriness of anchor joints, the L.C.C. experience is quite the opposite to Mr. Gibbings'. Anchored tracks cost one-half to maintain than unanchored. Although anchored joints might not be perfect, they enabled tracks to be kept in good order, as otherwise the expense of maintaining after three or four years would be well-nigh prohibitive. Grinding the rail surface on the L.C.C. system had been found satisfactory in the sense of prolonging very considerably the life of joints, and of making the repair of joints effective. The higher rail tread should be ground at least for 12 in. to 18 in. from the joint. Difference of section of adjacent rail ends was not the most concrete; the bolts were rendered practically immovable by this means. Mr. Welling exhibited a joint taken from the Camberwell New Road section of the L.C.C. tramway after a few years' service, in which the hammering had been so serious as actually to embed the flange of the rail in the top of the anchor rail. There is a two-minute service on this route.

Mr. STEPHEN SELLON said that Mr. Salter had put the question in a nutshell. Everybody would have an elastic rail bed were it not for the difficulty of the paving. In consequence, they had to offend every engineering law in the design of tramway track, and yet obtain a satisfactory result. The whole thing depended on the cost of breaking up the road for repairs and remaking it. He was strongly opposed to an elaborate system of anchor joints or anything of that nature, and there were many systems still working quite satisfactorily without these. He referred to the exhibit of the London County Council tramways joint as a "monstrosity," which, he said, would never have been put in except by a Corporation like the London County Council, with whom money was no object. Presumably, as this was the case, they would increase the depth of the concrete below the joint so as to obviate the difficulty which Mr. Sayers had pointed out. The trouble with the various new mechanical devices was that they were new, and that it took five years to ascertain if they were any good. It was, however, of no use to follow a set rule in designing a tramway track, as there were always particular circumstances to be taken into consideration on every route.

Sir CLIFTON ROBINSON, who was in the chair, said that his experience in London was that the more rigid the joint the better. He might suggest a modification to the Hon. Arthur Stanley's saying, and put it that it was all very well in the concrete, but wait until you get to the asphalt. Finally, he suggested that it was advisable for tramway companies to lay their own track and not employ contractors; for it was preferable not to have to follow a rigid specification, so that alterations from the general scheme might be adopted in particular instances.

Mr. GIBBINGS stated that he would reserve his reply, which he would communicate to the official circular of the Association.

Digitized by Google

On Friday morning the proceedings were opened by Mr. A. L. C. Fell (Vice-Chairman of the Association and Chief Officer of the London County Council Tramways), who gave a short address on the work of the Association.

Mr. A. L. C. FELL, referring first of all to the growth of the tramway systems in the United Kingdom, said that the total mileage of track, which in 1878 amounted to 269 miles, had, last year, reached the figure of 2,349 miles. The passengers carried annually had risen from 146,000,000 in 1878 to 2,454,000,000 last year, and the amount of capital invested from £428,139 in 1878 to over £64,000,000 for last year. Turning then to the work of the Association, Mr. Fell said that it was unfortunate that the report of the two sub-committees on brakes was not complete, as it would have provided matter for a good discussion. It was hoped, however, that it would be submitted to the Board of Trade before the end of the recess. The subjects of "Brakes" and "Rail Corrugations" were both suitable subjects for combined action on the part of the two Tramway Associations (namely, the Municipal Tramways Association and their own), and a report signed by the leading members of the Associations would have been more desirable than the separate reports now being framed. Although the headquarters of the Association must of necessity be in London, it was proposed, he said, to hold the Annual Congress in a fresh town every year. This matter would, however, be discussed in the official circular of the Association. With regard to the work of the various committees, that of the Income Tax Assessment Committee had been particularly successful, there being every hope that the Income Tax Commissioners would meet the views of the Association in this matter. After some appreciative remarks on the work of the secretary, Mr. de Turckheim, Mr. Fell called upon Prof. C. A. Carus-Wilson to deliver his lecture on "Rail Corrugation."

RAIL CORRUGATION.

In Introducing his subject, Prof. Carus-Wilson said that it was hardly necessary to explain what rail corrugation was, so he would commence by drawing attention to two facts connected with rail corrugation which seemed to indicate how the problem should be tackled. Firstly, the corrugation seemed, as a general rule, to take place only on one side of the track at a time; and, secondly, corrugation on one rail was generally accompanied by wearing of the check on the other rail, especially on curves. In the latter case the corrugations were to be found on the outside rail, while the check of the inner rail was cut or worn. With new wheels there was generally a clearance of about ¼ in. between the flange and the check, as shown in Fig. 1; but after some

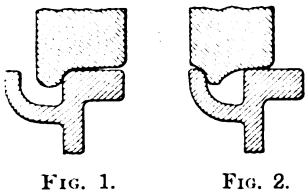


FIG. 1.

FIG. 2.

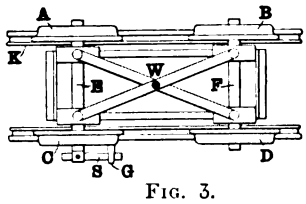

FIG. 3.

amount of wear, the flange could come in contact with the check, as shown in Fig. 2, and cut it.

To see what effect this grinding of the flange on one side of the rail had on the motion of the wheels, Prof. Carus-Wilson had constructed the model shown in Fig. 3. This consists of a three-foot length of 3½ in. gauge brass rail, on which runs a rigid four-wheel truck. A weight is so suspended from the centre of the truck *W* as to be distributed equally over the four wheels. The wheels *A* and *B* are keyed to the axles *E* and *F* respectively, while *C* and *D* are loose. If, now, the flanges of the wheels *A* and *B* are caused to grind against the check *K*, these wheels will run on a larger diameter than the wheels *C* and *D*, and for a given distance the latter wheels will rotate a certain number of times more than the former wheels. By rigidly coupling the wheel *C* to the axle *E*, by inserting a bar *S* through the slots of the axle and the stud *G*, the wheel *C* is forced to rotate the same number of times only as the wheel *A*, and so long as the rail is smooth, the wheel *C* will skid uniformly over the whole of the travel of the truck. With the aid of the model, the lecturer showed that this was the case, and he also described some experiments made on an 8-ton tramcar, with the permission of Mr. T. B. Goodyer, Manager of the Croydon Tramways, which gave evidence of a skidding action of 3 per cent. If, now, a spring is substituted for the rigid bar *S*, so as to allow a slight relative movement between the wheel *C* and the axle *E*, the following will take place. At first the wheel will not skid, but the spring will be bent. When the tension in the spring is sufficient to overcome the force of adhesion, the wheel will skid slightly, but so long as the rail is smooth and clean, the skidding will again be uniform, the spring being kept at a constant tension. The lecturer demonstrated this with the model, but then pointed out that the conditions under which the model was working differed in one important respect from actual conditions, namely, the rails were clean and smooth. Fine sand was then sprinkled on the rails, and on running the truck along the track a difference in behaviour was at once apparent. The skidding was no longer uniform, but intermittent; the spring was put in tension as before to a certain maximum amount, but then, instead of a uniform skidding taking place, the tension was entirely relaxed by a sudden twist of the wheel, and the skidding thus took place at intervals determined by the critical tension of the spring. The presence of grit on the rail has therefore the effect of preventing the uniform skidding which takes place on the clean rail, and of causing intermittent sharp skids of the wheel.

The lecturer said that he had, therefore, come to the conclusion that corrugation was due primarily to the wheels running on unequal diameters, which, combined with the presence of grit on the rail, would produce this intermittent skidding. To bear out this conclusion, the lecturer mentioned that corrugation was exceptionally bad along the Boulevard de Waterloo in Brussels which was flanked by sand-covered avenues; again, in Norwich, where the lines were frequently covered with the hard flint dust, the lines were badly corrugated, whereas in Coventry, where the equipment was exactly similar, no serious corrugation had been noticed. The distance between the corrugation marks, said the lecturer, depended upon the percentage skid and the limiting twist of the axle. If the limiting twist was represented by 1/16 in. at the rim of the wheel, then 3 per cent. of the distance between corrugation marks must equal 1/16 in. The car tested at Croydon had a weight of 4,000 lbs. per wheel, an axle diameter of 3¾ in., an axle length available for twisting of 48 in., and the coefficient of friction was 0·4. The twist estimated from these particulars was 0·073, and this, combined with the measured skid of 3 per cent., corresponded to a corrugation pitch of 2·4 in. The pitch of the actual corrugations varied between 2·25 and 2·75 in. Considering the matter from another point of view, a different value of the pitch was arrived at; thus the system, consisting of the two wheels and an axle, had a natural period of vibration, and a constant period of time would elapse between each swing. If this were the only determining factor, the pitch of the corrugations would be directly proportional to the speed of the car. Thus the pitch of the corrugations will vary under different conditions. The corrugation at Philadelphia, which had been stopped by stiffening the web of the rail with fishplates, was, the lecturer thought, due to the fact that side pressure caused the wheel to run on the throat of the flange, the head of the rail being deflected, as noticed, some 3/32 in. By stiffening the web, the deflection was prevented, and the wheel ran on the tread of the rim. If a groove is choked with dirt, this may also cause corrugation, as the wheel will run on its flange. Referring to the rail corrugation on the Eastern Bengal State Railways, the lecturer pointed out that a very hard brick ballast was used for the boxing between the sleepers on these railways. In some cases this had been replaced by a softer material, and the corrugations had disappeared. On the open girder bridges the corrugations were present only when the approach to the bridge was boxed with brick, which seemed to show that the corrugations were caused in the way suggested, the dust being sucked by the train from the approach on to the rails.

In conclusion, Prof. Carus-Wilson stated that there were four conditions which must exist at the same time to produce corrugation, namely, (1) a defective track producing grinding and check cutting; (2) defective rolling stock, *i.e.*, bad wheel section as shown in Fig. 2; (3) the presence of grit on the rail; and (4) the critical speed. The lecturer suggested no remedy, but stated that the first step towards a remedy was that all should be agreed upon the correct diagnosis of the disease.

The chairman, Mr. Fell, then announced that the lecture would be discussed at a meeting to be held at 4 o'clock on Friday, July 24th, at 35 Parliament Street, when the model shown by Prof. Carus-Wilson would again be on view one half-hour before the meeting. The country and out-of-town members present, who would not be able to attend that meeting, however, were asked to speak at once.

Mr. J. DALRYMPLE (Manager, Glasgow Corporation Tramways) stated that corrugations on the rails at Glasgow cost the Corporation from £10,000 to £15.000 annually, and that any remedy would be most acceptable. With the exception of a couple of

Digitized by Google

miles of rail the whole system was badly corrugated. He thought the lecture was an important contribution to an important question, but regretted that Prof. Carus-Wilson had suggested no remedy. Although the causes of corrugation might be what the lecturer had stated, he was doubtful if a remedy could ever be found. If a remedy was found, he hoped it would cost less to carry out than what the corrugations were costing them at present.

Mr. A. N. BANISTER (Norwich Electric Tramways Co.) said that after the first three years of running the corrugations on the rails at Norwich were very bad, extending over three to five lengths of rail; since getting rid of these in the usual manner, they had reappeared only in short patches of from 5 to 15 feet long. Corrugations had appeared on a slight curve laid in wood paving; at first they were on the outside rail only, but now they were on both. There had been an enormous amount of check cutting going on, but on the Newmarket road, their fastest, it had not been necessary to repair the check, although corrugation on this road was bad. Thus his experience did not agree with Prof. Carus-Wilson's theory.

Mr. G. M. GIBSON (Mountain & Gibson) suggested that the application of a differential gear might prove a remedy. There were trucks running with such gear already. Not only would much wear and tear on curves be saved, but corrugation and the breaking of axles might be prevented as well.

Mr. E. BENEDICT said that during his 22 years' experience on the Eastern Bengal Railways he had never heard of rail corrugation, and that he could not understand how it was that so much was made of it now. He had known cases when men had to be told off to sweep sand off the rails to allow the train to pass, but there had been no trouble with corrugations.

Mr. C. W. SHEPHERD (Edinburgh & District Tramways Co.) hoped that Prof. Carus-Wilson would inspect their tramway system in Edinburgh, as they had no signs of corrugation.

Prof. CARUS-WILSON, in reply, further explained the actual part taken by the grit in causing corrugation, stating that he thought that the presence of grit was essential, but that grit alone would not cause corrugation.

A vote of thanks was proposed by Mr. STEPHEN SELLON and seconded by Mr. J. DEVONSHIRE (Metropolitan Electric Tramways, Ltd.). The proceedings concluded with a vote of thanks to the chairman, Mr. Fell.

THE SUMMER VISIT OF THE INSTITUTION OF ELECTRICAL ENGINEERS, STUDENTS' SECTION

THE annual tour of the students' section of the Institution of Electrical Engineers was this year directed to Newcastle-upon-Tyne and the surrounding neighbourhood. The party numbered about twenty from London, while a considerable number of local students joined them at Newcastle.

Starting at St. Pancras on Monday, the 6th inst., a visit *en route* was paid to the works of the Midland Railway Company at Derby. The first visit in Newcastle on Tuesday was to the works of Messrs. R. W. Hawthorn, Leslie & Co., Ltd., where a considerable amount of marine work is passing through the shops. Probably the most interesting thing to electrical engineers to be seen here was the wire-core method of blading turbines.

These shops afford an excellent example of electric drive applied to heavy marine engineering. The nature of the work requires machines of a massive nature, and individual motor drive is considerably used. A three-phase supply is obtained from the mains of the Newcastle-upon-Tyne Electric Supply Co., Ltd., at a pressure of 6,000 volts, from which it is transformed down to 440 volts for power, and 240 volts alternating, to neutral for lighting. Two complete sets of oil-cooled static transformers are installed on the high-tension side, the low-tension board only being under the control of the works' staff. The lighting and power boards are separate on the low tension side, the latter being divided into five circuits, each having an oil-switch, a fuse in each phase, and an ammeter operated by a Reyrolle current transformer. The motors installed range from 5 to 50 h.p., and the circuits are, wherever possible, aerial, carried in pot insulators. This equipment is typical in general details of a large number of installations on Tyneside, operated by the supply company mentioned.

In the afternoon the works of Messrs. Ernest Scott & Mountain, Ltd., at Gateshead, were visited. One of the most interesting features is the recent addition of a high-tension three-phase supply solely for testing purposes by means of transformers which, operating normally at 6,000 volts from the mains of the County of Durham Electrical Power Distribution Co., Ltd., have tappings whereby voltage reductions of 1,000 volts at each tapping may be made.

On Wednesday morning a section of the extensive Elswick works of Messrs. Armstrong, Whitworth & Co., Ltd., were visited, comprising the electrical department and the gun shops. The principal features of the electric works of Elswick are described in a separate article on page 91 of this issue. In the afternoon Messrs. J. H. Holmes's works were visited, and here, again, the number of items of interest were considerably in excess of the space limits of these notes. The "Lundell" motor, which was amongst the first of the "round-frame" machines, still retains a position as favourite as evidenced by the number of machines passing through the shops. The testing room for small motors is most admirably arranged for the rapid testing of small motors, four benches supplied with special rapid-connection cables from a main test board being used either for direct or indirect Hopkinson testing. For speed tests a standard seconds pendulum operates through a relay into a single-stroke bell every quarter-minute, giving time to each testing assistant and dispensing with the second man usually necessary. A very fine collection of historic lamps was here shown to the students, including an old Maxim high-power lamp, whose filament was made from Bristol board, and an interior-screw Edison lamp. Holnies's original quick-break switch was also shown—interesting, because at one time thirteen firms were licensed to make switches under that patent.

On Thursday morning, Messrs. Clark Chapman's works were visited, where a large variety of electrically-operated winches were shown. Attention may be drawn to a type of motor-starter for ordinary duty, but constructed to the requirements of the Admiralty with an exclusion of slate. The system of electrical supply to the works is a mixed three-phase and direct-current equipment. In the afternoon the visitors emerged from the sphere of influence of the large power companies operating in this area by visiting the Consett Iron Works, where a 400 kw. Parsons turbo-set, running at 2,800 r.p.m., gives 800 amperes at 500 volts. It is assisted by two 350 kw. "Tyne" type Scott & Mountain generators, driven by three-cylinder compound engines. Electricity is used for arc and incandescent lighting, pumps, and small motors. In the pumping station are three sets of eight-pole Scott & Mountain 143 b.h.p. motors, running at 475 r.p.m., driving 3-throw plunger pumps, 16″ diameter by 22″ stroke. Water is used for cooling the rolls of the mills, and for passing round the nozzles on the blowers. To supply 220-volt current for the offices, a motor-generator and battery are installed in the pump room.

On Friday morning the shipyards of Messrs. Swan, Hunter & Wigham Richardson were visited, and also the mines of the Horden Collieries, Ltd., described on page 109. The final visit on Saturday morning was to the Carville Power Station of the Newcastle-upon-Tyne Electric Supply Co., Ltd. The chief feature of interest is the transfer of the distribution panels from the main switchboard in the power-house to a special "control room," where a chart of the whole system, extending in some cases to points 35 or 40 miles distant, shows at a glance the state of every trunk cable. Every operator on the system has to telephone to the control room before moving a trunk switch.

Electrically-propelled Ferry-boat.—According to the *Elektrotechnischer Anzeiger*, an electrically-propelled ferry-boat has been built recently at the Berninghaus Dockyards at Duisburg. The boat contains a battery of 160 cells, and can carry 645 passengers. This boat will take over the ferry service between Codesberg and Niederdollendorf on the Rhine.

The Census of Production.—Evidently the department of the Board of Trade which is carrying out the "Census of Production," is aiming at obtaining very complete statistical returns, far more complete and detailed than the ordinary general census. In our issue of July 2nd, we published particulars of the information that is being asked from manufacturers and others in the electrical and engineering trades, and we have now before us a copy of the form which is being sent out to the building and contracting trades. Information is required with regard to the total capacity of engines that are used, and this is to be divided up into the capacities of reciprocating engines, steam turbines, internal combustion engines, water-power, and other power. The capacity of dynamos used for generating electricity is also asked for, and the number of Board of Trade units which are generated during the year. In this case, also, separate totals are required of machines driven by reciprocating engines, steam turbines, and other power. The amount of electricity purchased during the year is also asked for—the capacity of dynamos to be given in kilowatts and of engines in horse-power, and the information is given in the instructions for filling in the form that a horse-power is 0·746 of a kilowatt, to assist estimates being made. As in the return for the electrical trades, there is both "compulsory" and "voluntary" information. All the questions mentioned above come in the former category, as do also questions relating to the nature of the trade or business, and the output during the year. Included in the details of output, the value of constructional and repair work, on railways, light railways, and tramways, telegraphic lines, telephonic lines, electricity lines, &c., are all to be given. The iron, steel, and fuel used during the year is desired as "voluntary" information.

THE ELECTRICAL EQUIPMENT OF HORDEN COLLIERY

ONE of the most interesting features of the recent visit of the Students' Section of the Institution of Electrical Engineers to Newcastle-upon-Tyne was the visit to a typical colliery, one of the many which abound in that district. The installation was interesting from the point of view of its completeness and self-contained nature, the electric generating plant for power purposes consisting at present of two high-speed compound direct-coupled engines and dynamos of 250 kw. capacity, manufactured by Messrs. Ernest Scott & Mountain, Ltd., of Gateshead, giving at 360 revolutions per minute a potential difference of 500 to 550 volts at the bus-bars. In order to compensate for increased line drop on the distribution system throughout the colliery at full load the generators are slightly over-compounded, and each machine is protected by means of overload and reverse current release circuit-breakers, situated on the switchboard.

The lighting installation consists of two Siemens and Crompton rope-driven generators of a not very modern type, delivering current at the bus-bars at 230 volts. One of these sets supplies the whole of the surface lighting of the colliery during the day shift and the other the street and private lighting of the village, as well as the colliery. The underground lighting is taken from the power set. In connection with this it is interesting to note that throughout the Northumbrian and Durham coal field area it is becoming customary, since the introduction of electric power into mines, to light up the streets of the pit villages adjacent to the mines, and in many cases to provide electricity for the interior lighting of the miners' cottages.

Power on the surface is supplied for the creepers, Zimmer screens, raising and lowering gear and coal belts, each of these being driven through worm-reducing gear running in an oil-bath by a 15 h.p. totally enclosed shunt-wound motor of Messrs. Mather & Platt's make, running at 600 revolutions per minute. Although this is kept going continuously for 20 hours out of the 24, the temperature rise is exceedingly low. The starters, which are of the wire-resistance type, are fitted with double-pole switches, fuses, and overload and no-volt releases. Messrs. Mather & Platt's motors are also installed for running the tiplers, jiggers, &c., which are driven through friction and bevel gearing by 30 h.p. shunt-wound partially enclosed motors running at 600 revolutions per minute, the necessary speed reduction being obtained by various size pulleys on the belt drive. These motors are placed in a special motor-house fitted with a distribution switchboard, on which are placed, besides the main double-pole switches, fuses for every motor and sub-circuit, the whole being protected by a circuit-breaker of the B.T.-H. pattern. The motor starters and overload and no-volt releases for the tipplers and jiggers are placed on panels at the bottom of the switchboard.

One of the most important functions of electricity in coal mines is the ventilation of the system, as by Board of Trade regulations, a current of air has to be kept continuously in circulation under heavy penalties. At the Horden Collieries ventilation is secured by means of a Sirocco fan, driven by two Scott & Mountain multipolar shunt-wound motors, each of 160 h.p., and coupled one at each end of the fan shaft by means of flexible couplings of the interwoven belt type. These motors can be run either singly or together, either in series or in parallel, according to the speed or load required, through the medium of a series parallel switchboard, fitted with automatic circuit-breaker having a no-load release, and also non-inductive resistance to take up back E.M.F. As these motors are of the 10-pole construction and the ampere turns on the fields are heavy, great care has to be taken to deal with the E.M.F. on breaking circuit, necessitating the insertion of non-inductive resistance. Liquid starters are used for these motors, and on an eight weeks' non-stop full load run the temperature rise is quite normal, the field being only slightly warm.

The endless rope haulages are driven by 100 h.p. motors, compound wound and fitted with commutating poles, made by Messrs. Crompton & Co. The speed and torque are varied by means of B.T.-H. controllers permitting of reversal and a good range of speed. The motors run at 620 revolutions per minute, the necessary reduction being obtained by belt-drive and spur gearing. In order to operate each motor a specially enclosed watertight and gas-proof switchboard is provided, containing an automatic circuit-breaker, double switch and fuses, ammeter and voltmeter, and non-inductive resistance frames. In order to prevent any danger from electric shock, the motors, with their resistance frames and other accessories, are well earthed.

Pumping is undertaken, both for the water supply to the colliery and town, and for the removal of drainage water from the shafts and workings. For the former purpose motor-driven turbine pumps are installed, capable of pumping 200 gallons per minute to a 400 ft. head when running at a speed of 1,000 revolutions per minute, while the drainage water is pumped to the surface by means of a 35 h.p. Scott & Mountain motor-driven three-throw pump, situated down the mine in the five-quarter seam. The speed of the motor is 800 revolutions per minute, a belt drive being used for the pump. In the Hutton seam is another three-throw pump capable of delivering against a 1,020 ft. head, having 9 in. rams, and being rope-driven by a Scott & Mountain shunt-wound variable speed motor of 160 h.p.

Among the minor applications of electricity in this mine may be mentioned the operation of the granary, workshops, &c., which are all motor-driven by 15 h.p. and 30 h.p. shunt-wound Mather & Platt motors, whose switches are operated from distributing boards in the shops, and whose starters are fitted with overload and no-load releases. The lamp-cleaning machines are also motor-driven, and the miners' lamps are lit by electricity on bank and below ground by specially designed air-tight igniters, operated by induction coils and accumulators. The lamp is lit in the secondary circuit of the coil, and the accumulators are charged on bank by means of a motor-generator. The lighting below ground is obtained from the 500-volt circuit by means of two 250-volt lamps in series. The top and bottom decks and pass-byes are illuminated by two light gas-tight oyster fittings at every 12 yards, while the staples and haulages are fitted with single light air-tight ship fittings, each circuit being protected by a fuse in each pole, and all conduits are sufficiently earthed. The shaft signalling is done by bells from each seam to bank and winding engine, on the Morse system. The signalling underground is accomplished by simple bell circuits, the wires extending right in-bye.

In order to secure continuity of supply, the current is conducted down the shaft by means of bitumen insulated double steel armoured cables, 61/12 size, supported in clamps at intervals of about 20 fathoms, the ends terminating at specially designed change-over junction boxes, allowing the current to be changed over through the seams and down the other shafts in the minimum of time in case of breakdown of a section. The main gas-proof switch-boxes underground are very massive, and fastened about three feet from

Digitized by Google

the ground. A brick cabin is built around them and the door locked, a danger plate in red letters being very conspicuous at the shaft bottom. The switches are let into the wall, and the door plates in front of them locked as before, these collieries being worked strictly on the basis of the Mining Acts. We are indebted to the management of the Horden Collieries, Ltd., for their courtesy in giving us the particulars of the well-arranged and up-to-date electrical equipment of their colliery, which is of considerable interest, in view of the rapid extensions in the application of electricity to mines.

THE USE OF ACCUMULATORS FOR PEAK LOAD

MR. A. M. TAYLOR, replying to the discussion on his Paper, reported on pp. 65–67 of our last issue, says that Mr. Wilmshurst, Mr. Watson, and Mr. Raphael had evidently gained the impression that he had based his costs on a one-hour basis. The Fig. 1 of his Paper, which we published, he now explains, was a purely hypothetical curve upon which none of his deductions were based. For his estimates, he states, the kilowatt capacities were based on a three-hour rating. He has analysed dozens of load curves, with a view to introducing batteries, and says that, fogs excepted, the estimates in his Paper will hold for towns having large power and tramway loads, such as Manchester, Liverpool, Glasgow, and Birmingham, provided that only some 33 per cent. of the peak is taken up by the cells. In such towns, he maintains, the fog load rarely exceeds the equivalent of 66 per cent. of the peak load (maintained over eight hours), and consequently the steam plant is capable of meeting it, with very little, if any, assistance from the batteries, so that these need be no bigger than those considered in his estimates.

"While on this question," Mr. Taylor adds, "I may point out that if the batteries are put in for 50 per cent. of the peak, a 'fog load' *averaging* 75 per cent. of the mid-winter peak, maintained over 7–8 hours, can be dealt with by the combined plant without *any* extra expenditure on battery power. I know of no towns out of London where this demand is exceeded, and think the above will show that I have carefully considered the question of 'fog loads,' and have not, as some critics appear to think, ignored it."

He has authority to state that responsible makers will maintain cells at their full initial capacity for ten years on a 9 per cent. basis. The watt-hour efficiency, he argues, is really hardly material "with current at 0·2d. per unit (including repairs)."

In reply to the demand for figures and further information as to the American batteries, he states that he has first-hand information that the first battery in Chicago was put down absolutely in place of new steam plant, and to give 11,000 amperes for 1¼ hours; and he has every reason for believing that subsequent batteries were put down for a similar purpose. For New York, Sir William Preece recently published a curve showing a distinct proportion of the immense peak taken up by cells. [Reference to this curve, published in ELECTRICAL ENGINEERING, Vol. III., p. 462, will show, however, that the cells supply only about 5,000 kw. of the total peak load of 117,000 kw., which hardly supports Mr. Taylor's argument.—ED. E.E.] As regards the cost of working in Chicago, he thinks Mr. Parshall recently stated this to be only 0·25d. per unit in his evidence before the London Committee.

Electrical Coalcutters in Staffordshire Mines.—From the report of Mr. H. Johnstone upon the inspection of mines and quarries in the Stafford inspection district, abstracted in the *Iron and Coal Trades Review*, it appears that 17 electrical coalcutters are in use in that district, as compared with 32 worked by compressed air. The amount of coal cut during 1907 by the electric cutters is, however, more than double the amount cut by compressed air, being 286,507 tons against 130,225 tons. The electrically-driven machines are classified as follows:—13 of the disc type, three of the bar type, and one of the chain type.

Tungsten in Queensland.—A report to the *Queensland Government Mining Journal* states that a large amount of tungsten is present in the quartz seams of Noble Island, situated about 80 miles north of Cooktown. The veins have been worked on the surface only for about four years with good results. There is, however, no permanent water supply and no serviceable timber for mining purposes on the island.

ELECTRICAL SCIENCE

British and American

Electrolysis of Water Vapour by Sparks.—In the year 1861 Perrot showed that if sparks from an induction coil be passed through water vapour, the decomposition into hydrogen and oxygen occurred all along the spark and not merely at the electrodes. He found also that the gas collected at the electrodes was a mixture of hydrogen and oxygen, an excess of oxygen occurring at the anode and an excess of hydrogen at the cathode. J. J. Thomson, on repeating these experiments, found that the length of the spark had some influence, for with short arc-like sparks hydrogen appeared mostly at the anode and oxygen at the cathode, while with long sparks the gases changed places. In 1902 Chapman and Ledbury noticed that the separation of the products of electrolysis had something to do with the position of the inflow of the vapour into the spark. The excess of oxygen occurred, they found, at the pole furthest from the point of inflow of vapour. In the *Philosophical Magazine* for July, A. Holt and E. Hopkinson inquire experimentally whether the separation of the gases is a diffusion phenomenon. One of their experiments consists of arranging the spark between platinum wires sealed into the leg of a T tube, and making a stream of water vapour at 15 mm. pressure enter the tube at one end of the cross-piece, divide, and leave the tube at the end of the leg and the other end of the cross-piece. Of course, only the vapour passing along the leg of the tube is submitted to the spark, yet a large proportion of hydrogen is found in the vapour stream emerging from the end of the cross-piece. An excess of oxygen appears, of course, in the stream from the leg of the tube. This shows that the hydrogen diffuses against the stream of vapour much more rapidly than does the oxygen. By analogous means the decomposition of carbon-dioxide was examined; and as carbon-monoxide and oxygen have much the same rate of diffusion, neither gas preponderates at any place. This does not account, however, for another observation of Chapman and Ledbury: that the total amount of water vapour decomposed when the vapour enters the tube near the cathode is very much greater than when the vapour enters near the anode. The present authors suggest that the vigorous disintegration of platinum cathodes, which is well known to be greater than the disintegration of platinum anodes, is the chief cause of this phenomenon. To test whether this metallic spray from the anode can affect—catalytically or otherwise—the total amount of decomposition, the authors made parallel experiments, in a special form of tube, on electrodes of platinum and aluminium. The latter metal disintegrates very slightly, and is, besides, not affected by water vapour at moderate temperatures. The tube resembled an ordinary vacuum tube, but was provided with an inflow pipe at one end, and with an outflow pipe at the other. The figures given by the authors show that with platinum electrodes the decomposition when the inflow of vapour occurs near the cathode is four times as great as when it occurs near the anode; while with aluminium electrodes the difference is one of only three per cent.

Continental

Positive Electrons.—Jean Becquerel has got one step further in his attempts to prove the separate existence of positive electrons, *i.e.*, positively charged particles having numerically the same ratio of charge to mass as the negative electrons hitherto known. His method is described in the *Comptes Rendus* for June 22nd. Two vacuum tubes, A and B, communicate through a capillary portion. An anode is mounted in A, and a perforated cathode in B, so that B contains canal rays. On approaching the finger or an earthed wire to the tube B, a new cathode is formed, which attracts the positive rays and produces a whitish patch inside the tube. This is best seen at a pressure of 1/500 mm. of mercury. The patch follows the finger, and may be made fairly small and well-defined. If now a magnet is brought near the tube, the spot is displacement with exceptional ease, and the displacement is always in the sense indicating positively charged particles. Now an easy displacement in a magnetic field has hitherto only been obtained in the case of cathode rays, which are negatively charged particles. The author isolated a beam of these new rays by attracting it out of the tube B by means of another cathode placed at the further end. The beam colours the gas in the third tube blue, and the glass orange. When a screen of willemite is used, the beam colours it a greenish yellow. This beam behaves much like an ordinary canal-ray beam, so long as the cathode rays are not prominent in the region of the second cathode. But when the pressure is made so small that cathode rays are freely developed in that region, the beam is easily deflected in the sense which indicates a positive charge. This action of cathode rays in eliciting positive electrons is made evident by directing an independent cathode stream on to the second cathode, so as to cross the path of the canal rays. As soon as that takes place, the positive electrons are freely produced. The author supposes that negative electrons, impinging upon positively charged atoms, are capable of extracting some positive electrons from them. If positive electrons are produced without such special facilities, they probably have a very short free path, and rapidly re-enter into combination. In doing so, they may possibly build up the same species of matter from which they were extracted, or perhaps a new species of matter.

THE FIRE ON THE LANCASHIRE AND YORKSHIRE RAILWAY

MR. A. P. TROTTER has now issued his report to the Board of Trade on the fire which broke out in a "trailer" coach on the Liverpool and Southport Railway, on April 30th, soon after the train left Freshfield Station, on the down line. There were but few passengers, and no one was injured. The fire may be divided into two kinds, (*a*) the primary fire due to and supported by and in the immediate neighbourhood of the electric arc which started it, and (*b*) the secondary fire which spread by ordinary combustion when inflammable woodwork had caught fire. The cause of the primary fire may be divided into two considerations: (*a*) the defect, undoubtedly a short circuit from a positive cable to "earth," that is, to the underframe of the carriage, and (*b*) the persistence of the electric current after it had been automatically cut off. The effects of the electric arc were confined to a distance of a foot or so from the spot where the fire broke out below the floor, at the extreme corner of the under-frame, where the cables turn to rise up and pass through the floor. The cable which probably was the cause of the fire is called, on this railway, the "main trolley cable," and consists of 37 strands of No. 13 S.W.G., insulated with pure and with vulcanised rubber, and is taped and braided with fire resisting braidings. This and other cables are run "bunched" in a wooden casing lined with thin uralite. Where they bend upwards the uralite is cut away, and the braiding of the cable lies against the wood. After passing up through the floor they are well taped and compounded, but such protection against the descent of moisture is of a highly inflammable nature.

Mr. Trotter continues:—If I had been asked to make a critical comparison between the wiring of this carriage and those of the London lines and of the North-Eastern Railway lines before I examined this accident, I should have said that (1) the "bunching," that is to say, the running of several cables side by side in a common trough or casing, (2) the cutting away of the uralite and the exposure of bare wood at the upward turn, (3) the number of bunched cables and wires between the panel and the end of the carriage, compare unfavourably with the practice elsewhere of running each cable in a separate iron pipe, these pipes in the case of the North-Eastern Railway being carefully arranged not to cross each other and all carefully "earthed" to the frame. The woodwork of the Underground Railway Company of London is treated with chemicals which render it non-inflammable. The exact nature of the defect which resulted in the short-circuit is not ascertainable. There had been much rain, and a defect such as a stab through the insulation of a cable by a chisel, which would give no trouble and might escape detection under insulation tests while everything was dry, would certainly develop in the presence of moisture.

When cables are run in iron piping, moisture sometimes condenses in them and may accumulate in considerable quantities. It has been suggested that drain holes should be provided. While these would prevent any accumulation of water they would leave the cables subjected to damp air in wet weather or under the conditions, whatever those may be, of condensation or sweating. I recommend that when cables are run in iron pipes, they should be sealed by wooden ferrules, parallel inside, slightly tapered outside, split in two or perhaps three parts, and driven well into the pipes. Uralite, while capable of standing the temperature of ordinary red heat, will melt when close to an arc, and is not an insulator. It is quite incapable of resisting the primary fire of an accident of this kind.

In this case, the arc was more severe than any that I have known in London. This is no doubt because it was a dead short from positive to negative. It is estimated that it lasted not more than two or three minutes. Its intensity was shown by the considerable amount of iron which was melted. A stout knee, a diagonal, and the headstock were fused. Several pounds of iron were melted from these.

The report then dealt with the persistence of the electric current after it had been automatically cut off. The part of the line where the accident occurred is supplied with current from the Formby Power Station and the Freshfield Battery Station. Automatic circuit breakers are provided between the three converters and the bus bars at Formby, each breaker being set to open at 1,800 amperes. Breakers are also provided between the bus bars and north and south feeders, set at 3,500 amperes each. Each breaker has a knife switch in series with it. At the Freshfield Battery Station one breaker, set at 2,800 amperes, and its knife switch are placed between the battery and the bus bar, and between the north section (the up and down conductor rails being coupled together at a section pillar), there is a breaker set for 2,800 amperes, and a knife switch, but for the south section, that is, the section between the battery station and Formby (the up and down rails being connected together at a section pillar) there is a knife switch and no breaker. It appears that at 1.8 p.m. the converter breakers opened at Formby and on being replaced they stayed in. Two minutes later they opened again. Simultaneously with the first opening of the breakers at Formby the battery breaker opened at Freshfield with a loud report. They were replaced and opened two minutes later. It must be assumed that the short-circuit started after the train left Freshfield Station, since nothing was noticed at the stop at Freshfield. Formby could supply 3,500 amperes through the north feeder, Freshfield could supply 2,800 from the battery, and could pass another 2,800 amperes from a sub-station further north at Birkdale, reverse way through its line breaker, bus bar and knife switch, making a total of 9,100 amperes. It is not improbable that a current of 2,000 to 8,000 amperes, insufficient to open the breakers, did most of the mischief of the primary fire, and the apparently simultaneous opening of the breakers, and the explosive opening of the one at the battery sub-station, indicate that at a certain stage it quickly increased and largely exceeded 9,000 amperes. During the two minutes after the breakers were replaced the fire started again, and reached the same point, again opening the breakers. Had the sub-station attendants, after the current had been cut off by the opening of the automatic circuit-breakers, guessed that there was something wrong, and kept them open, it is probable that the fire would not have spread, and it certainly would have been less severe and easily controlled. But circuit-breakers frequently open, and it is the practice on this line to put them back at once, on the supposition that they have come out in consequence of a momentary over-load. The practice about replacing circuit-breakers differs with different companies. The rule of the Lancashire and Yorkshire Railway is that:—"If the rotary circuit-breakers alone open without opening the line circuit-breakers, the attendant then trips one line circuit-breaker, and replaces the rotary circuit-breakers, and then replaces the line circuit-breaker which he has tripped. If a line circuit-breaker blows, this is always accompanied by the blowing of the rotary circuit-breakers: in this case the rotary circuit-breakers are replaced and then inquiries are made from the adjacent sub-stations and signal-boxes as to whether anything has been noticed wrong; if the reply is satisfactory, the line circuit-breaker is then closed again. If the rotary circuit-breakers blow violently (even if a line circuit-breaker does not blow) it is probable that the attendant would make some inquiries before replacing. In any case, if a circuit-breaker blows on its first replacement, full inquiries would be made before it is again replaced. The sub-station attendant is guided to a certain extent by the manner in which the circuit-breakers blow."

Meanwhile, the driver of the train put his short-circuiting bar across the rails and prevented any further supply. The fire was then subdued by chemical extincteurs, and the train started again after a total delay of only eighteen to twenty minutes.

The current fed to a line may be of three kinds, first, the ordinary working current used by the motors; second, general leakage current, and third, current due to such an accident as this. To these may be added the current used for lighting the trains, but this is perhaps insignificant. It would be an advantage if attendants at sub-stations could discriminate between these currents. It might be worth while trying if a telephone working on an induced circuit in shunt to such a length of conductor as is available in a sub-station would indicate (1) a hum due to the motors, (2) comparative silence due to leakage, or lighting, disturbed perhaps by the sliding of the shoes, (3) a possibly characteristic roar due to an arc. It appears that while attention may be given with advantage to details of wiring and to gradual alteration of the carriages, most careful consideration is immediately necessary as to the arrangement of the circuit-breakers, their time limits, and length of line controlled by each, and to the procedure to be adopted by sub-station attendants in replacing them. Shoe fuses appear to be of minor importance. They must be so rated that two can easily take the maximum starting current of a train. Should a short-circuit occur between a shoe-fuse and a bus-line, that fuse may go, but the other three in parallel with it will pass a serious current The severity of this fire was the result of the heavy current which passed. The feeders at Formby and at Birkdale, though supplying the up and down rails through separate knife switches, are controlled by a single circuit-breaker, and the rails are cross-connected at the section pillars. If each feeder were provided with a circuit-breaker, and the switches at the section pillars were kept open, except for emergency, repairs, or tests, the breakers could be set at a much smaller current. This alteration would not increase the number or length of the feeders. Any one section of up or down line would then be limited to the current (with reasonable margin) required to start a train.

The report concludes with the following recommendations:—(1) In construction of new rolling stock, and in alterations and repair of the present stock, care should be taken to protect cables, not only against water under ordinary conditions of weather, but under conditions of high wind or driving snow. (2) The lay-out of feeders, circuit-breakers, and section switches should be arranged with the view of limiting for each section the current distributed to that section, with a reasonable margin in excess of the maximum requirements of that section, and the sections should be, where possible, of such a size that one train only is likely to start on it.

ELECTRICITY IN AGRICULTURE*

By Sir Oliver Lodge

Results of Experiments on an Industrial Scale

INTRODUCTORY.

SOME thirty years ago a Swedish professor named Lemström sought to elucidate the aurora borealis by trying to imitate its appearance by electrical experiments. For this purpose he produced high-tension discharges of various kinds, and sent them through vacuum tubes until he got an appearance very like those of the Northern Lights. Some of these experiments he conducted in his greenhouse, and he noticed incidentally that the plants seemed to thrive under the treatment, and that the electrification thus produced in their neighbourhood appeared to do them good. He also noticed, as remarkable, the flourishing development of plants in Arctic regions, where the sunlight was very weak; and he attributed part of this growth to the influence of electric discharges.

He says that when the plants in the North of Norway, Spitzbergen, and Finnish Lapland have resisted the frequently destructive night frosts they show a degree of development which greatly surpasses that of plants in more southern regions, where the climatic conditions are more advantageous. This rich development appears principally in the fresh and clear colours of the flowers, in their strong perfume, in the rapid development of the leaves on the trees, and their scent, but particularly in the rich harvest which different seeds—such as rye, oats, and barley—will produce when, as before stated, they are not destroyed by the frosts. From a bushel of rye sown they will often produce 40 bushels, and from barley 20 bushels, and so forth. It is the same with grass. These results are attained although the people cultivate their soil very imperfectly, using only ploughs and harrows of wood.

He pursued the matter by careful observation, taking test plants in pairs or groups, electrifying one group—that is to say, discharging some electricity into the air above them—and keeping a similar group away from the electricity, in order to be able to compare them. Then he photographed the two groups side by side, and found in nearly all cases a marked improvement as the result of the electrical treatment. He concluded that the needle-like shape of the leaves in fir trees, and the beard on the ears of most cereals, have the discharge of electricity as their function, and finds that they do act in this way.

This observation and these experiments of Professor Lemström were not, indeed, the beginning of the application of electricity to plant growth, because pioneer attempts had been made long before, as will be mentioned directly, but it was the beginning of a thorough and scientific treatment of the problem. Attempts of a different kind had also been made. Plates had been sunk in the ground, and a current passed between them among the roots of plants; but whatever effect is thus caused is of a totally different kind to that excited by high-tension electricity supplied to the air above them. Both in a manner are natural processes. There are natural earth currents, and these must flow among the roots of plants, though whether they produce an appreciable effect may be doubted.

There is a natural atmospheric electrification, and this must be playing an important part in many phenomena. Atmospheric electrification is responsible for the formation of rain and hail. During fine weather the electricity in the air is usually of one sign, mainly positive. When wet weather sets in, the electricity in the air usually changes sign, becoming negative. The whole subject is a large one; a great deal is known about it, and vastly more remains to be known; but meanwhile it can hardly be doubted that the electrification of the air has some effect on growing plants. For it is found that, under the influence of sunshine, electrified plants can give off electricity into the air from the leaves; and the fact that the air is electrified relatively to the soil requires that the plants shall be electrified too, so that in all probability they are in a constant state of slow electrical discharge, which becomes more rapid when the sun is up. In what way this discharge of electricity from the growing tips, and hair, and surface generally, really acts must be studied and reported on by physiological botanists; but it is natural to suppose that it cannot be without influence, and reasonable to think that that influence must be beneficial—a hypothesis which direct experiment confirms.

Possibly in some sunny countries the effect is excessive, and might with advantage be moderated; but in this climate it turns out that artificial supply of electricity does increase the rapidity and assist the amount of growth. At any rate, the experiments of Lemström, which were repeated and extended by others, clearly pointed in that direction. So when, after some preliminary experiments at Bitton, Mr. J. E. Newman, of Gloucester, acting in conjunction with Mr. R. Bomford, of Salford Priors, determined to try the phenomenon on a really large scale, and came to me to see if I could help them electrically, and enable them to maintain a continuous high-tension discharge for hours together each day over ten or eleven acres by means of power furnished by an oil engine and dynamo, I very willingly assented, and set my son, Mr. Lionel Lodge, upon the job.

Those interested in the experiments are much indebted to the enthusiastic co-operation of Mr. Bomford. It may be interesting to note that it was at a farm belonging to Mr. Bomford's father that the first steam ploughing in England was done.

Professor Lemström was undoubtedly the pioneer in this sort of work, though circumstances connected with the natural electrification of the atmosphere, and with the discharge of electricity from various surfaces, have been pertinaciously examined by Professors Elster and Geitel

THE ELECTRICAL ARRANGEMENTS

The method is to stretch over the field to be treated a number of wires on poles, something like low telegraph wires, but high enough for loaded waggons and all the usual farming operations to go on underneath the wires without let or hindrance. The wires are quite thin, and are supported by elaborate high-tension insulators on posts. They extend over all the acreage under experiment, a "control plot" of similar land under similar conditions being, of course, left without any wires.

The overhead system of wires covered about 19½ acres of ground. The wires were mounted on insulators placed upon larch poles, some 15 ft. high, which were placed in rows, the rows being separated by a distance of 102 yards, and the poles in a row being 71 yards apart. Stout telegraph wire carried the current along each row, while thin galvanised iron wires, placed some 12 yards apart, were stretched between the rows, and acted as the discharge wires. In this way 22 poles were sufficient to support the wire over the 19 acres.

Roughly, only one pole per acre is required; therefore, the inconvenience is practically nil. Owing to the flexible suspension, risk of breakage to the wires is very small. (During the two years the wires have been up at Bevington, apart from a few wires broken at harvest time by catching in top of extra high waggon load, only one wire has fallen.)

The system of conductors is connected at one post with a source of positive electricity at a potential of something like a hundred thousand volts, and with sufficient power to maintain a constant supply of electricity at this kind of potential. Leakage immediately begins, and the charge fizzes off from the wires with a sound which is sometimes audible, and with a glow which is visible in the dark. Anyone walking about below the wires can sometimes feel the effect on the hair of the head, as of a cobweb on the face. They are then feeling the stimulating action of the electrification.

The electrification is maintained for some hours each day, but is shut off at night: it is probably only necessary to supply it during the early morning hours in summer time, and in spring time or in cold cloudy weather for the whole day, or during the time of the

* Appended to the article sent us by Sir Oliver Lodge were some interesting notes and details supplied to Sir Oliver by Mr. Newman and Mr. Bomford, who have carried out the experiments with the assistance of Mr. Lionel Lodge. To facilitate reading and subsequent reference, and to avoid repetitions, we have recast the article to some extent, by bringing these additional notes into the body of the article.—ED. *E. E.*

Digitized by Google

plant's greatest activity. But at what stages of the growth of a plant the stimulus is most effective has still to be made out. However, in the case of wheat, both the ear and the straw is valuable, and the electrification is accordingly applied for a time each day during the whole period of growth until stooling begins.

The power required to generate the electricity is very small, for although the potential is high the

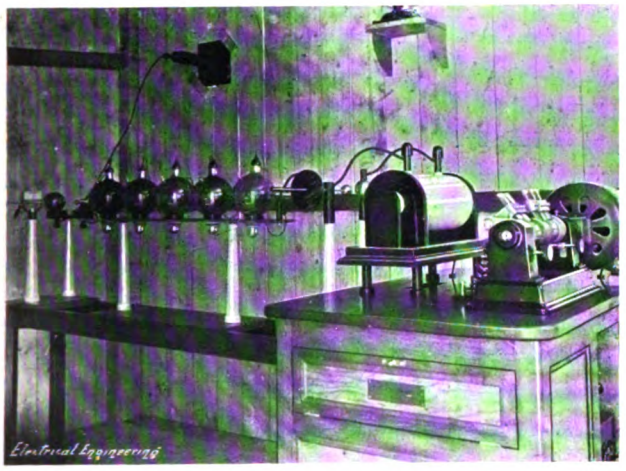

FIG. 1.—INSIDE THE TRANSFORMER SHED, SHOWING SIR OLIVER LODGE'S INDUCTIVE BREAK, SPECIAL COIL AND HIGH TENSION VALVES; FOR SUPPLYING CONTINUOUS CURRENT AT 100,000 VOLTS.

quantity is insignificant, and the energy is accordingly comparatively trivial. It is known that even when natural atmospheric electricity has accumulated intensely, and has become a thunderstorm, the quantity even then is quite small, though the potential is so enormous that the flashes are of astonishing violence and power while they last. The electricity can be generated in more than one way. It can be generated by the revolving glass plates of a static influence machine, usually known in this country as a Wimshurst machine; or it can be generated by transforming the current from a dynamo up to high tension, and rectifying to one direction. The first is in many respects the simplest, and was used in the early and small-scale experiments, but it can hardly be regarded as an engineering method adapted to continuous or rough use. The latter is the one which was adopted for the present trials.

The power is generated by a two-horse oil engine driving a small direct-current dynamo (3 amperes at 220 volts) in an outhouse of the farm. Thence the current is taken by ordinary overhead wires to a suitable weather-tight hut in the field, which contains a large induction coil and the rectifying apparatus. The only moving part here is the make and break contact in the primary circuit, and if the original dynamo had been an alternator, even this might be dispensed with. The high tension current from the secondary coil is rectified by means of vacuum valves in accordance with a patented device of my own, and then the negative pole is connected direct to earth, and the positive electricity is led by a specially insulated conductor out of the shed to the nearest post of the overhead insulated wires, which are thereby maintained at continuous high-positive potential.

In 1906, owing to the late delivery of some of the apparatus, the work had to be carried on with a somewhat improvised generating station at the commencement on March 16th; by the end of May, however, the installation was completed, and worked fairly continuously during the rest of the season, the current being supplied intermittently until July 10th, by which date the wheat had been in ear about a fortnight. From March 16th to July 10th, 1906, inclusive, the plant ran 621¾ hours on 90 days, and the average pressure corresponded to a ¾ in spark. In 1907, the plant was run 115 days, from March 28th to July 27th, 1,014 hours, and the average pressure corresponded to a ½ in. spark.

EXPERIMENTS IN 1906.

The acreage under treatment was spread over two different fields. One was a wheat field 18½ acres in extent. Eleven acres of this were under treatment, 2½ acres sown with Canadian wheat and 9 acres with English wheat. As a "control plot," seven acres of the field were sown with the same wheat, Canadian 5½ acres and English 1½ acres. The Canadian wheat was "Red Fife," and the English "White Queen." In the second field, 6½ acres of barley was under treatment, and a half-acre lot was planted with potatoes, mangolds, &c.

The results on the barley field, including the small plot, had to be neglected owing to the great local variations produced by the very irregular manuring the field had previously undergone; the wheat field, however, as far as one could judge, had been very uniformly treated previously.

In the wheat, difference was noticeable at an early stage, the young blades on the electrified part being, in the opinion of many observers, of a darker green. The crop was judged as considerably heavier by several practical observers, and the straw was, on an average, from 4 in. to 8 in. higher. Both experimental and control plots came into ear at about the same time, but the Canadian wheat under treatment was ready

CONTROL. ELECTRIFIED.

FIG. 2.—COMPARISON OF ELECTRIFIED WHEAT WITH WHEAT GROWN IN THE CONTROL FIELD UNDER THE SAME CONDITIONS; AN AVERAGE PLANT BEING TAKEN IN EACH CASE. NOTE THE BROADER LEAVES AND GREATER NUMBER OF SHOOTS OF THE ELECTRIFIED WHEAT.

for cutting some three or four days before the control area.

The crops were gathered separately from the electrified and unelectrified plots, and the resultant yields were as under:—

Bushels of Wheat per Acre.

(Estimated corresponding increase in straw not measured.)

	Electrified.	Non-electrified.	Increase.
Canadian (Red Fife) ...	35½	25½	39 per cent.
English (White Queen)...	40	31	29 ,,

Moreover, the electrified wheat sold at prices some 7½ per cent. higher, several millers in baking tests finding that it produced a better baking flour. No

Digitized by Google

theoretical conclusions can be drawn from this fact, owing to the uncertainty existing as to what factors determine the strength of wheat, but it is interesting to note that greater strength is usually accompanied by increase in percentage of total nitrogen. [Later researches indicate that it is a function of the sugar present.]

Mr. J. Kirkland, of the National School of Bakery, Borough Polytechnic, found the evidence from baking tests supported by the average of dry glutens from all his tests thus:—

In the electrified	11·15 per cent.
In the unelectrified	10·35 ,,

The somewhat poor yield of wheat obtained from the unelectrified portion of the field is probably explained by a deficiency in lime, which has now been rectified. Further, the wheat was spring sown, and Red Fife, under this condition, does not usually yield good crops. The experiments are being repeated upon wheat during the present season, and strawberries are also under treatment once more.

EXPERIMENTS IN 1907.

In 1907, wheat was grown again in the 1906 wheat field. Current was cut off from most of the barley field, which was down to clover and rye grass. $8\frac{1}{4}$ acres in an adjoining field were planted with strawberries (Stirling Castle) in March, approximately $2\frac{3}{4}$ acres having a wire network erected over them. Mangolds were planted between the strawberry rows.

The wheat field was during the early spring given a dressing of lime, 10 cwt. to acre, 4 cwt. to acre bone meal drilled in, the unelectrified part given $1\frac{1}{2}$ cwt. sulphate of ammonia, and the electrified part $\frac{3}{4}$ cwt. Barley had been grown on the strawberry field in 1906, and this was given 10 tons to acre of farmyard manure, which was ploughed in.

Result of Wheat Crops, 1907.

(*Variety, Red Fife, Spring Sown.*)

$7\frac{1}{2}$ acres un-electrified gave 239 bus, 38 lbs. Head Wheat, 15 bus., 1 lb Tail.
11 ,, electrified ,, 455 bus., 50 lbs. ,, ,, 17 bus., 27 lbs. ,,

Or, summarising as before:—

Bushels per Acre (Head Wheat).

Electrified.	Un-electrified.	Increase.
41·4	32	29 per cent.

Electrified wheat brighter and a better sample. Increase due to better stooling and also better filling out of ears.

Strawberries.—This being the first year, the crop was necessarily very small, and was picked chiefly to see if any increase had been obtained. The result showed a 35 per cent. increase. Earlier ripening was also observed.

Mangolds.—It was found impossible to weigh either the whole or a part of this crop. Estimated increase (from number of cartloads removed), 25 per cent. Analysis showed an increase in the sugar where electrified, but the results varied considerably.

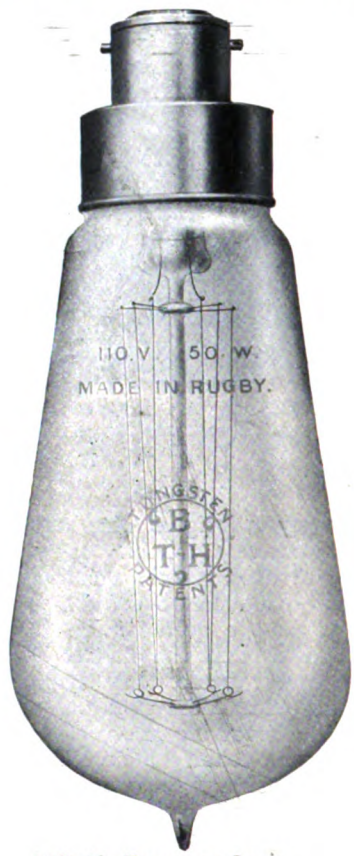
Raspberries.—Small plots of raspberry canes showed a marked improvement in growth. (A curious point about the raspberries was that the foliage and fruit on the old canes showed no difference, but that the new growth, particularly after the old wood was cut back, showed an enormous difference in favour of the electrified. Manurial treatment exactly similar.

Tomatoes.—Small plots of tomatoes also showed large increase in the crop.

Details of some earlier experiments made by Mr. Newman, and also a review of the history of the subject, were given in a Paper read by Mr. J. H. Priestley, B.Sc., before the Bristol Naturalists' Society (*Proceedings* of the Society, Fourth Series, Vol. I., Part III., 1907; or ELECTRICAL ENGINEERING, Vol. III., p. 477).

THE B.T.-H. TUNGSTEN LAMP

WE referred briefly in our description of the collective exhibit of the electric supply companies of London at the Franco-British Exhibition to the metal filament lamp which the British Thomson-Houston Co. are putting on the market. We are now able to give an illustration of one of these lamps. These lamps are the outcome of experiments which have been in progress for a considerable time, and, like the B.T.-H. Edison lamps, are made entirely at Rugby. In view of the patent complications which only too often impede the progress of new industries, it is interesting to note that the company definitely undertakes to defend all claims or actions for infringement of British patents in respect of the sale of tungsten lamps of its manufacture. The lamp illustrated is of the 110-volt 50-watt size, which has a bulb $6\frac{1}{4}$ in. long by $2\frac{3}{8}$ in. diameter, gives approximately 40 British candle-power. We are not able to give very full particulars as to the nature of the filament beyond stating that it is composed of pure tungsten, and can be used with equally satisfactory results on continuous or alternating current circuits working a temperature corresponding to an efficiency of 1·25 watts per British candle-power. In addition to the standard 100-125-volt 40-c.p. lamp, smaller lamps are made for 25 and 50 volts. The bulbs of these are $4\frac{1}{2}$ in. long and similar to ordinary carbon lamps, for which they may be substituted without alteration of shades or fittings. The 25-volt lamp is made in two sizes, $12\frac{1}{2}$ and 20 watts (approximately 10 and 16 candles); the 50-volt lamp is made in one size only, 20 watts (approximately 16 c.p.).



B.T.-H. TUNGSTEN LAMP.

Care is taken in marking those suitable for running in series with a distinguishing number. A special form of holophane shade is supplied, which gives an excellent distribution of light with these lamps. This can be supplied either clear or sand-blasted, but the best lighting effect can be obtained by using a clear holophane shade with a lamp having the tip end frosted. The sand-blasted shade, however, gives a very soft, bright effect with a clear lamp, and eliminates all the glare incident to the clear type. Where lamps hang in the direct line of vision the sand-blasted shade is desirable, but as this type somewhat modifies the candle-power distribution, it is recommended that the clear type be used whenever the lamps are out of the direct line of vision. The dimensions are $4\frac{3}{4}$ in. deep, $6\frac{3}{4}$ in. wide, and the shade is attached by a gallery fitting the ordinary shade ring.

The Telephone and Consumption.—Those who have been interested in the recent endeavour to create a feeling of alarm with regard to the danger of infection from telephone mouthpieces should read a logical and well-written review of the subject in the *Times* of last Saturday, evidently from the pen of a medical man who is in a position to speak with authority. The article concludes:—"To keep a telephone clean must, from æsthetic as well as sanitary reasons, be regarded as desirable, but to be scared by the discovery of a few hungry tubercle bacilli is neither logical nor justified."

Robertson Lamp Works Sports.—On Saturday last the Robertson Social and Athletic Club held their second annual sports at Mill Hill Park, Ealing. A very full programme, including running races, "lamp" races, cycle races, and tugs-of-war, was provided, and in the evening a concert by the Robertson Choral Section was followed by a dance. The Enfield Town Band played selections during the afternoon and in the evening for dancing. A "relay" running race for the Wilson Challenge Cup, competed for by Robertson's and the G.E.C., London, was won by the latter team. The prizes were presented by Mrs. C. Wilson. The Hon. Secretary, Mr. G. H. Freeman, is to be congratulated on the success of the afternoon.

CONTROLLERS FOR LARGE MOTORS

THE increasing application of large motors to industrial purposes has rendered it necessary for designers to carefully consider the construction of suitable controllers. Owing to the difficulties experienced in the construction of satisfactory metallic controllers, there has been some tendency to adopt controllers of the liquid type for motors of 100 h.p. and upwards. The liquid type of controller has the advantage of being cheaper to construct than the metallic type; on the other hand, it is quite unsuitable for installing in many situations, and has disadvantages owing to the insulation difficulties and the use of liquids which are more or less evaporated and steamed according to the working conditions, with the consequent introduction of moisture in the atmosphere, which in many cases is not permissible. The usual standard method of building metallic controllers has been to employ a series of fingers, which, under spring pressure, make contact on a series of segments on the controller barrel. This type of construction has been generally satisfactory for dealing with small motors and with continuous current, which permits of the use of blow-out magnets; destructive arcing has been successfully dealt with. The great disadvantage, however, of this type of construction is the very small break obtainable, and with controllers for two- and three-phase motors the tendency has been to immerse the controller in oil in order to damp the arc, and it is now generally admitted that oil-immersed controllers are most suitable for alternating current motors, and they have therefore been standardised by most makers.

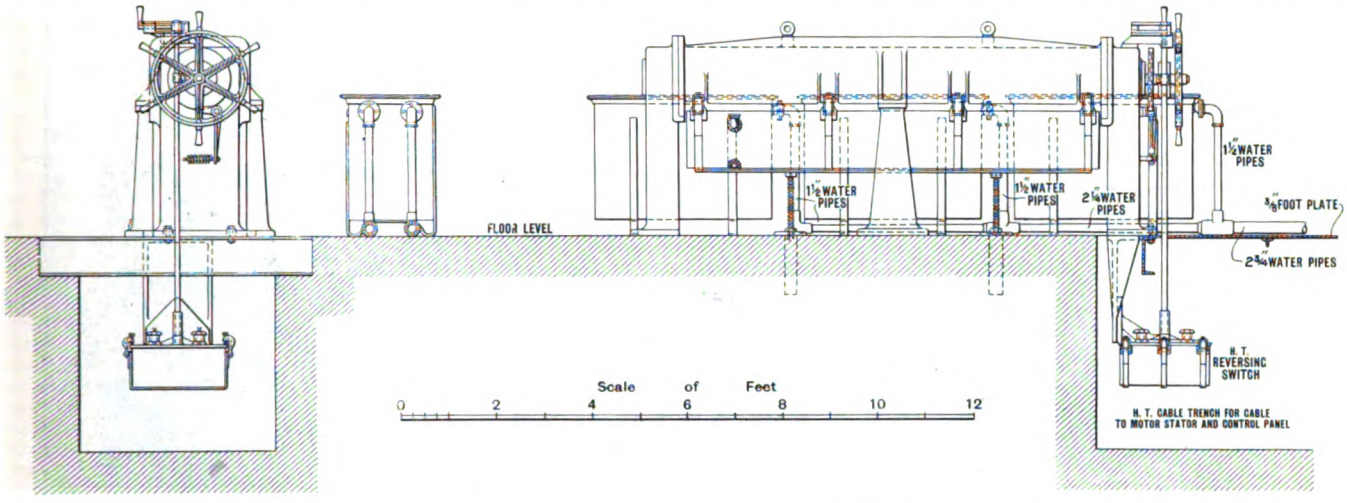

FIG. 1.—GENERAL ARRANGEMENT OF 400 H.P. 2,750-VOLT 3-PHASE OIL-IMMERSED CONTROLLER, WITH RESISTANCES AND SEPARATE REVERSING SWITCH.

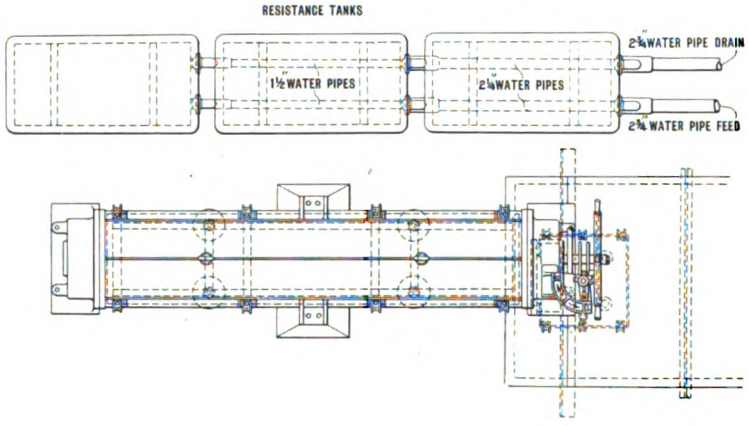

FIG. 2.—REVERSING SWITCH.

Serious difficulties, however, have been encountered with large controllers in oil built on the finger and drum principle owing to the difficulty of dealing with large currents with this type of contact, and also where many contacts are necessary the very small breaks obtainable. The supervision and maintenance costs owing to pitting and destructive arcing have therefore been considerable.

In order to overcome these difficulties, a new line of controllers have been designed to meet heavy conditions of service. A large example of the new pattern controller is illustrated in Figs. 1 and 3. This is for use with a 400 h.p. 2,750-volt three-phase reversible haulage motor, and it is arranged to provide 50 per cent. continuous speed regulation if required, and also provision is made for running dead slow for winding in the haulage rope.

The reversing is arranged for in the usual way by crossing two of the stator phases by means of a high-tension change-over switch, shown in Fig. 2, placed below in the cable trenches and operated by a lever near the controller hand-wheel. With this arrangement all the high-tension gear is situated away from the operator. The reversing switch is interlocked with the controller hand-wheel, and can only be operated when the hand-wheel is in the off position. The controller is arranged to cut resistance in or out of the rotor circuit, and is provided with 16 steps per phase, the rotor being wound for 520 volts. Each step of the controller consists of a quick make and break knife switch, giving 4½ in. break, and each switch is individually operated by

Digitized by Google

its own cam fixed on the main spindle, the whole series of switches being oil-immersed. The controller is constructed on the loose-handle principle, and the speed of the break is independent of the operator, and therefore the controller cannot be held in an arcing position. The usual brake-drum is provided to define the various steps. With this type of apparatus the makers claim that the upkeep and maintenance is reduced to a minimum, and they have therefore adopted the same principle of construction for controllers of all sizes and types.

cooling pipes through which water is pumped being used to cool the oil. This arrangement keeps the space occupied by the resistances to a minimum, and provides a flexible arrangement, as more or less water may be used to cool the oil according to the working conditions of the load from time to time, and the heat generated is conveyed out of the haulage room. It is usually possible to obtain an ample supply of water in most mines from the existing pumps.

The resistances are built up on the unit principle, thus no

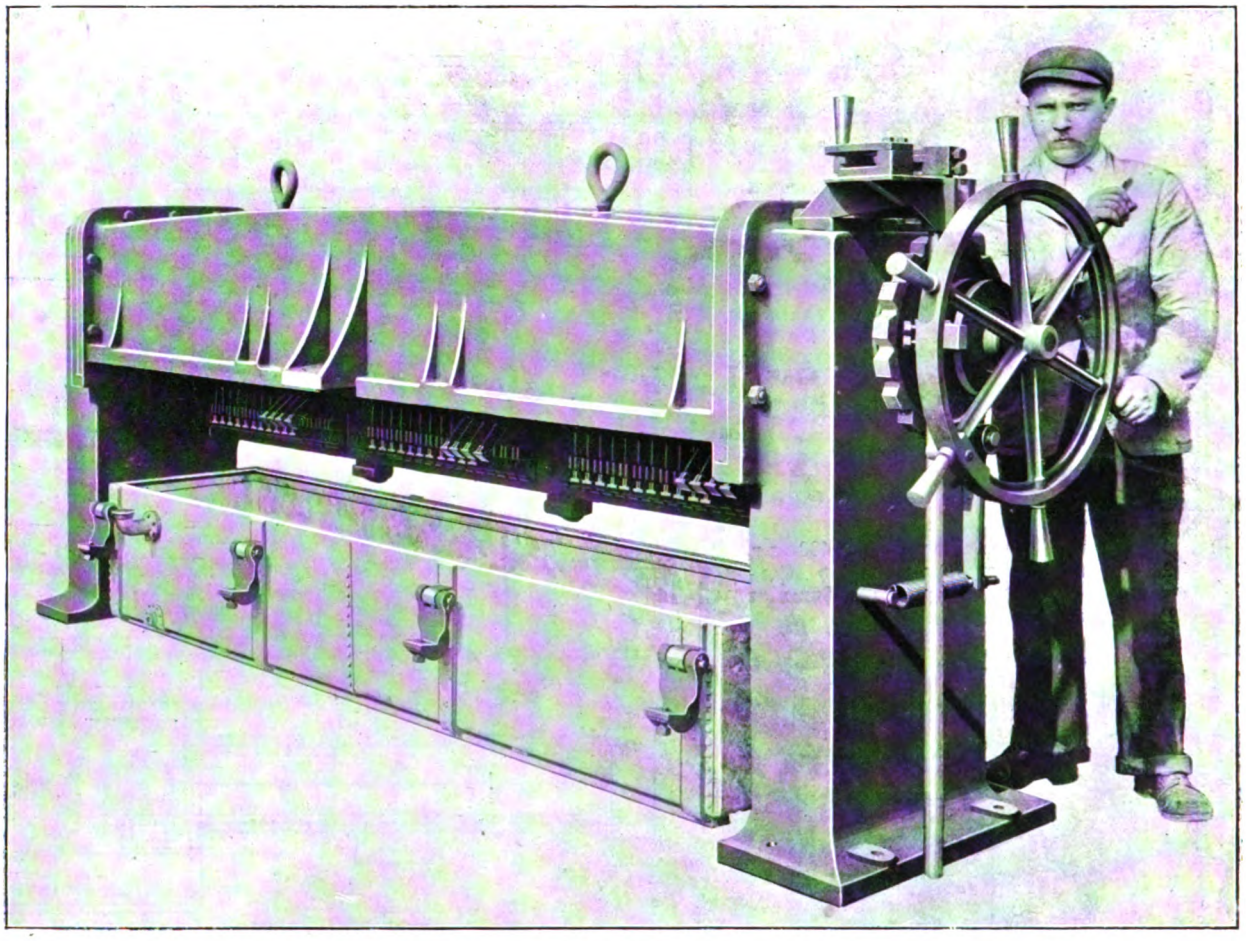

FIG. 3.—CONTROLLER FOR 400 H.P. 2,750-VOLT THREE-PHASE REVERSIBLE HAULAGE MOTOR.

The question of resistances for use with these large controllers has also received very careful attention. Where considerable energy has to be dissipated in resistances in confined spaces, such as haulage rooms, the questions of providing space and keeping the temperature of the room normal have to be considered. In order to deal with these problems and to produce resistances particularly suitable for colliery work, the resistances have been placed in enclosed tanks filled with oil, a system of copper cables whatever are used other than the cables from the controller to the terminals shown on top of the resistance frame.

These patent controllers have been put on the market by Messrs. Engineering Instruments, Ltd., and are made in two patterns. For alternating- and continuous-current motors they are made in a vertical type, with self-contained resistances, and in the horizontal pattern oil-immersed for alternating-current motors only.

Visit of Electrical Engineers to Germany.—Last October we had the pleasure of taking part in a tour organised by Mr. Leonard Andrews and his colleagues of the Key Engineering Co. to the Continent, the main object of which was to afford an opportunity to English engineers of inspecting examples of large gas engines and electrical installations, and a full account of the trip appeared in ELECTRICAL ENGINEERING, Vol. II., page 599. The success of this trip has led to the organisation of a further tour of a similar nature for the benefit of those who were unable to accompany the party last year. The itinerary has been somewhat modified, but some of the same installations are included. The party left London on Monday, travelling *viâ* Calais to Brussels, and on Tuesday took train from Brussels to Metz, whence they were conveyed on motor-cars to the German Government mines at Heinitz, where a large installation of gas engines running on coke oven gas was inspected. The journey was then continued by motor-car to Saarbrucken. Yesterday morning, after visiting the works at Saarbrucken of Messrs. Ehrhardt & Sehmer, the manufacturers of most of the engines inspected, the party again drove over to Metz and crossed the frontier to Homecourt, where there is a fine installation of gas engines at the French Government's rolling mills. To-day is devoted to a trip down the Rhine in a private launch from Bingerbruck to Coblence, and to-night will be spent at Dusseldorf. To-morrow's programme includes a visit to Messrs. Thyssen's work at Muelheim in the morning and the large gas-engine installation at the Bruckhausen Iron and Steel Works in the afternoon. The return to London is to be made on Saturday. The party includes the following gentlemen:—Mr. H. Talbot (City Electrical Engineer, Nottingham), Alderman Sir John Turney (Chairman of the Electricity Committee, Nottingham), Mr. Councillor Clarke (Nottingham), Mr. W. W. Lackie (City Electrical Engineer, Glasgow), Mr. J. Dalrymple (Manager, Glasgow Tramways), Mr. J. Ferguson (Engineer, Glasgow Tramways), Mr. R. H. Chattock (City Electrical Engineer, Birmingham), Mr. Councillor Ellaway and Mr. Councillor Freeman (Birmingham), Mr. S. J. Watson (Borough Electrical Engineer, Bury), Mr. A. C. Cramb (Borough Electrical Engineer, Croydon), Mr. Percy Allen (Runcorn), Mr. Lymn (Power Gas Corporation, London), Mr. Crampton, Mr. H. B. Mathews, Mr. E. W. Cowan (Messrs. Cowans, Ltd.), and Mr. R. B. Slacke & Mr. Leonard Andrews, of the Key Engineering Co.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published July 9th, 1908

A full list of these was published in our last issue. The following are abstracts of the more important specifications.

Names in brackets indicate communicators of inventions from abroad.

1907 Patents

8,445, **Electric Induction Furnace.** GRÖNDAL KJELLIN CO. AND J. HÄRDÉN. This invention relates to induction furnaces consisting of an annular fusion chamber surrounding an iron core, the primary winding being wound on the iron core, and the material in the fusing chamber serving as the secondary winding. The lining of these fusion chambers needs to be frequently repaired, and, to avoid the delay due to the slow hardening of a new lining, the present invention provides means whereby a damaged lining, which is formed in a metallic casing, can be quickly removed and a new one substituted in a very short time. An illustration of this type of furnace was given on page 18 of ELECTRICAL ENGINEERING for July 2nd, 1908. Two claims, three figures

8,947, **Manufacture of Metal Filaments.** ALLGEMEINE ELEKTRICITÄTS-GESELLSCHAFT. Thin filaments are made from finely powdered tungsten or molybdenum, or from oxides of these metals, with the addition of a binding material. To free the filaments from the carbon contained in the binding material, they are moderately heated in a limited quantity of air. Afterwards they are heated to a temperature higher than 1,500° C. in a reducing, carbon-free gas, for instance hydrogen, in order to reduce the oxides and sinter the filaments together. If this is done in an electric vacuum furnace, the latter must be lined with thorium or magnesium oxide to prevent fusion of the filaments to the sides of the furnace. Three claims.

21,584, **Three-wire Generator.** J. BURKE. A direct-current generator for supplying a three-wire distribution system. One or more auxiliary windings are wound in the same slots as the main armature winding, but with half the number of turns. If one auxiliary winding is used, one end is connected to a point on the main winding, and the other end to a slip-ring on which bears a brush in connection with the neutral conductor of the three-wire system. If more than one auxiliary winding is used, they are connected together at the slip-ring, the other ends being connected to equidistant points on the armature winding. The neutral conductor is thus maintained at a pressure half-way between the two outer conductors, as an E.M.F. is generated in each auxiliary winding, which, if added to the instantaneous value of the potential of the point of the winding to which it is connected, gives a constant potential at the slip-ring. The auxiliary windings also afford a path for the out of balance current. Where the system is much out of balance, better results are obtained with more than one auxiliary winding. The auxiliary winding must be so distributed that its parts are subjected to magnetic variations similar to those to which the main winding is subjected. Five claims, eleven figures.

22,302, **Method of Neutralising Induction.** BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). To protect telegraph or telephone conductors which run adjacent to rails used as return conductor on alternating-current railways from induction, a neutralising conductor connected in shunt to the rails is placed near the conductor to be protected. This will neutralise the electromagnetic induction, and, since the rails are earthed, will also partly neutralise the electrostatic induction. Resistances may be required in the shunt circuit to reduce the current to the proper amount. For the same purpose a transformer may be used, the primary winding being in series with the rails and the secondary with the neutralising conductors. Four claims, four figures.

1908 Patents

1,159, **Voltage Regulator.** W. H. THOMPSON. A synchronous machine and a series commutator machine are connected in parallel with the mains, and the shafts are connected by a differential gear mechanism. The synchronous motor will rotate at a constant speed irrespective of pressure variations, but the speed of the series motor will vary with the mains pressure. The rotation of the annulus of the differential gear, when the speeds are not equal, is caused, by a suitable mechanism, to vary the number of turns in the primary of a transformer, to the secondary of which the load is connected. The synchronous motor can be excited with direct current supplied from its own armature if this is supplied with a commutator. One claim, two figures.

6,409, **Suspension of Metal Filaments.** C. PAULI. It has been proposed to keep metal filaments in tension, and at the same time allow contraction, by inserting a spring in a glass tube between the yokes or carriers of the filaments. It has been found that the tensile strength of the filaments is so low when incandescent, that the spring is strong enough to break the filaments. According to this invention, the expansion of the spring is limited by suitable means. One claim, one figure.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.

Summaries of the more important of these patents will appear in our next issue.

1907 Patents

6,528, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Motor control systems.
9,009, RITCHIE. Telautographs.
11,926, BRITISH THOMSON-HOUSTON CO. (*Allgemeine Elektricitäts Ges.*). Controllers for cranes and lifts.
14,183, ENDERLEIN, LANDWEHR, & SCHULZ. Electrical signalling system for railways.
14,259, BLUNDELL. Ignition devices.
14,262, BROWN. Electric telegraph apparatus.
14,263, STONEHAM. Thermally-actuated contact makers.
15,058, KING. Separating iron from flour and grain.
15,079, ADLARD. Electrical heating apparatus.
15,100, STRAY. Electric primary clocks.
15,555, PECK. Equalising-devices for alternating current circuits.
15,966, VANDERVELL. Electric lamps for motor cars.
16,911, ELECTRIC IGNITION CO. & HALL. Electric ignition apparatus.
16,912, ELECTRIC IGNITION CO. & HALL. Magneto-electric ignition apparatus.
16,959, LAKE (*Brown Automatic Indicator Co.*). Reply or tell-tale telegraph.
17,457, HICKLEY. Electrolytic current rectifiers.
18,112, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Vapour condensers.
18,790, LAIRD. Electric time switches.
18,881, BRITISH THOMSON-HOUSTON CO. & DAWSON. Dynamo-electric machines.
21,255, COLLER. Electrical fuses or cut-outs.
21,403, DE CASTILHO. Electric and percussion primers.
21,551, COOPER. Control systems for electrically propelled vehicles.
22,123, TURNER. Brakes for tramcars.
22,648, SCHAFFLER *recte* GLOSSL, & WEISS. Apparatus for electrically firing mines.
23,708, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Control of alternating current motors.
24,299, TIMAR & VON DRECER. High-tension electric lamp.
24,363, PRINCE (*Dr. Paul Meyer Akt.-Ges.*). Switching devices for advertising purposes.
26,810, RUTHERBURG. Concentration of tungsten ores.
27,750, ROSING. Electrical transmission of optical images.
27,790, HELBIG. Electrical process for oxidising nitrogen.

1908 Patents

1,131, CAMPBELL & WILLIAMS. Magnetic stands for tools.
1,532, SIEMENS & HALSKE AKT.-GES. Electric signalling.
1,547, LANGE. Radio-telegraphy.
3,986, ALLGEMEINE ELECTRICITÄTS-GES. Electrically-driven rolling mills.
4,602, WEHRSEN. Discs for influence machines.
4,757, GRAHAM. Electric bells.
6,587, EGNER & HOLMSTROM. Microphones.
7,374, WOLHAUPTER. Insulated railway rail joints.
8,300, CREED & COULSON. Telegraphy.
10,394, SIEMENS BROS. & CO. & FERREIRA. Mechanism for electrically-operating railway signals.

Complete Specifications open to Public Inspection before Acceptance.

1908 Patents

9,449, F. KRUPP AKT.-GES. GERMANIAWERFT. Electrically operated heating devices.
13,101, WILLIAMS. Party-line telephone selectors.
13,133, DEGOUMOIS. Brakes for electric cars.
13,184, ZANDER. Electric melting furnaces and pots.

Expiring Patent

The following patent expires during the current week after a life of fourteen years :—

14,001 of 1894. **Single Line Railway Control.** E. TYER. Apparatus for electrically controlling the issue of a staff or similar pass at stations on a single-line railway by electrically locking or opening a box containing the staff at a distant station.

Digitized by Google

LOCAL NOTES

AUSTRALIA: *Brunswick and Coburg.*—Proposals have been made for installing an electric light and power plant in these districts. According to the *Australian Mining Standard*, the suggestion of the company from which the scheme emanates is that a power house shall be erected at Brunswick, and that a tram service shall be inaugurated between the two places. A 25 years' lease is required.

BELFAST: *Tramway Employees' Grievances.*—The district secretary of the Tramcar Cleaners' Union in Belfast has complained to the Corporation with regard to the treatment of the men for having taken part in meetings calling attention to the conditions under which they are working. The men have passed a resolution leaving the matter in the hands of the union officials, and, in the event of a climax being reached, it is stated that assistance will be rendered by the Belfast Trades Council and other labour organisations in the country.

BOURNEMOUTH: *Tramway Accounts.*—The Borough Electrical Engineer's report to the Tramways Committee for the year ended March 31st shows that 1,908,938 units were generated, an increase of 31,135 units over the previous year; 1,654,026 units were used for traction, 138,444 for street lighting, 43,919 for car-shed lighting, 30,763 for car-shed power, 39,777 for generating station lighting, and 12,009 for generating station power. The total working expenses, including interest and sinking fund, amounted to 1·262d. per unit, or 2·75d. per car mile, and the money value was £12,939. The expenses are slightly higher than last year, owing to the increased cost of coal. The Electrical Engineer recommends the installation of further generating plant and condensing plant. The Traffic Manager, in his report, stated that the system now covers 21·718 miles of route, comprising 29·44 of track, of which the Corporation owns 17·08 miles in Bournemouth, 5·26 miles in Christchurch, and are lessees of 7·10 miles in Poole. The traffic receipts amounted to £85,745, an increase of £2,404, whilst motor-omnibus receipts decreased by £44 to £278. The total receipts amounted to £86,225, an increase of £2,044 over the previous year. The number of passengers carried was 13,924,418, an increase of 498,229, whilst the car miles only showed an increase of 1,845, the total being 1,760,239. The working expenses amounted to £52,753, a decrease of £485, notwithstanding extra expense incurred by reason of the Workmen's Compensation Act. Including the expenditure upon the motor omnibuses, this figure was increased to £53,163, which is about £2,000 below the estimates for the year. The total tramway expenses were 7·19d. per car mile, a reduction of 0·07 per car mile over the figure for the previous year, whilst the working expenses, exclusive of electric power, amounted to 5·26d. per car mile against 5·28d. The cost of power was reduced from 1·98d. per car mile to 1·93d. There was a gross balance of £33,062, which is £2,479 in excess of the previous year's gross balance. The ratio of working expenses to receipts has been reduced from 63·66 to 61·66.

BRENTFORD: *Condition of Tramway Track.*—A letter from the Board of Trade was read at the last meeting of the Council, stating, with reference to complaints as to the condition of the tramway track, that Col. Yorke would be sent to inspect the line. It was arranged that the Chairman and other members of the Council, and the Surveyor, should meet Col. Yorke when the visit took place.

BRIGHTON: *Electricity Accounts.*—At the last meeting of the Corporation, the accounts of the electricity department, which were abstracted in our issue for June 25th, were passed.

BROMLEY: *Electricity Staff Outing.*—The annual outing of employees of the Bromley Electric Light & Power Co. took place last week at Margate.

BURNLEY: *New Plant.*—In connection with the putting down of a 750-kilowatt generator, a deputation is to visit Durham to inspect a direct-current turbo-generator. The Electricity Committee is in doubt whether to instal a turbine or reciprocating engine.

CARDIFF: *Tramway Administration.*—A discussion took place by the Electrical and Tramways Committee on Thursday with reference to the 10 per cent. which is charged to the tramway account upon all work in connection with tramway track allocated to the Public Works Committee. This amount has hitherto been regarded as a contribution towards the establishment expenses of the Public Works Committee, and the Finance and Public Works Committees have each been asked to appoint five members to discuss the matter with the Tramways Committee. Last year the amount paid by the Tramways Committee to the Public Works Committee under this head amounted to £700, and it is stated that in the current year it will be about £1,400.

CHATHAM: *Runaway Tramcar.*—As a car belonging to the Chatham & District Light Railways Co. was descending a sharp hill in Middle Street, Old Brompton, on Thursday, the brakes refused to act, and the car gradually increased its speed until at the bottom of the hill it left the rails and dashed into the wall surrounding the Chatham Dockyard. There were only three passengers on the car, but there were no serious injuries.

COATBRIDGE: *Electricity in Mining.*—A few years ago, owing to the lessees of the Summerlee Colliery being unable to come to terms with the owners, this property was compelled to be shut down. The Summerlee Iron Co., however, has now negotiated a long lease of the collieries, and they have been re-opened. The new arrangement for the working of the pit includes electrically-driven tipplers, screeners, washers, and centrifugal pumps. The only use which will be made of steam in connection with the pit will be for the winding engines.

COVENTRY: *Electricity Accounts.*—The accounts for the electricity undertaking for the past year show a profit, after meeting capital charges, of £5,647, against £5,114 for the previous twelve months. The number of consumers has increased from 951 to 1,020, and the connections from 140,177 to 171,133 8-c.p. lamps equivalent. The number of units sold has increased from 3,950,785 to 4,822,114, and the revenue from £27,145 to £31,852. Working expenses have increased from £11,028 to £15,388, this being largely attributable to the increased price of coal. The capital expenditure during the year amounted to £38,947, bringing the total to date of £218,907.

CRETE: ***Telephones.*—A British Consular report states that in January last the Crete Government called for tenders for the establishment of a telephone system in the island. The only tender received, however, was from a Cretan firm, but it could not be considered as it was unaccompanied with the necesary financial guarantee.

DARTFORD: *Electric Supply by Power Company.*—The Rural District Council has received notice from the South Metropolitan Electric Light and Power Co., Ltd., of their intended application to the Board of Trade for a Provisional Order authorising the supply of electricity in the Council's district.

DOVER: *Admiralty Supply.*—The Admiralty Electrical Engineer has notified the Corporation that it will probably be necessary to modify the clause of the contract with regard to electric supply relating to the maximum demand, in order that this may be increased to 500 kw. for power and 150 kw. for lighting. The Electrical Engineer, reporting upon this, states that the larger supply will necessitate an expenditure of £1,100. The matter is still under consideration, and further report will be presented.

DUNDEE: *Trolley Omnibuses.*—The proposal to adopt trolley omnibuses for the outskirts of Dundee has been further discussed by the Tramways Committee in conjunction with other members of the Town Council. Mr. Peter Fisher, the Tramways Manager, has planned a car suitable for local requirements, which will accommodate 24 passengers, and cost from £600 to £700 each, three such cars being contemplated. It has been unanimously agreed by the Tramways Committee to adopt the system, and details are to be placed before the Board of Trade for their sanction.

EALING: *Electricity Supply by Private Owner.*—At the meeting of the Town Council on Thursday, the Town Clerk reported the result of the proceedings against the Ealing Hippodrome for having supplied Messrs. Lipton's, Ltd., with electricity. In view of future action the matter was discussed in private. At the police court hearing at Brentford it was stated that an arrangement was entered into by the Town Council with Mr. Walter Gibbons for the supply of current to the Hippodrome on special terms. There was a restaurant attached to the Hippodrome, leased by Messrs. Lipton, and, Mr. Gibbons supplied them with current, the effect being to put the Council in the position of supplying electricity in bulk, which it had no power to do. For the defence it was urged that the agreement entered into with the Town Council by Mr. Gibbons covered the whole of the buildings at the Hippodrome. Mr. Gibbons, giving evidence, said when he first took over the Hippodrome he approached the Council with a request to be supplied at cheaper rates. He was refused, and thereupon obtained expensive machinery to generate his own current. Before it was installed the Council came to him with an offer to supply at a lower rate, and he got rid of the machinery at a loss of £250. The Bench held that a technical offence had been committed, but decided to dismiss the information under the powers of Section 1 of the Probation of Offenders Act, 1907, on payment by the defendants of two guineas costs.

EDINBURGH: *Electric Lighting Tariff.*—The Electricity Committee recommend that consumers using electricity during restricted hours should be allowed a reduction of $\frac{1}{8}$d. per unit, and that consumers who use their motors for three or four hours per day throughout the year should also be granted a similar reduction. It is further recommended that the price to lighting consumers for the current year shall be reduced by $\frac{1}{8}$d.

Non-statutory Power Supply.—At a Convention of royal burghs in Edinburgh on Friday, Bailie Murray reported that he had brought the question of the supply of electric power by non-statutory companies in Scotland before the Annual Convention of the Incorporated Municipal Electrical Association, and it had been left to the Council to deal with the matter. It was decided to appoint the Town Clerks of Partick and Dundee to represent the Convention at any meetings or representations to Parliament, and a circular is to be sent to all burghs owning electrical undertakings drawing their attention to

Digitized by Google

the matter, and asking them to support the attitude of the Convention.

EPSOM: *Position of Electricity Undertaking.*—The Lighting Committee have held a special meeting to consider the financial position of the electricity undertaking. The accountant submitted an approximate statement as at September 30th next, showing an estimated excess of liabilities over assets of over £400. The Committee asked that the Council should transfer £475 from the district fund to the electric lighting account forthwith, this sum to be subject to adjustment at the close of the Council's financial year. After long discussion at the last meeting of the Council a motion for the adoption of the recommendation for the supply of £475 from the district fund was withdrawn, the recommendation not being adopted.

ERITH: *Tramway Intercommunication.*—Negotiations are still proceeding between the Urban District Council and the Bexley District Council with a view to effecting tramway intercommunication. The Bexley Council offered to lease to the Erith Council, on certain terms, the Bexley tramway from a point in Market Place, Bexley Heath, to Northumberland Heath. The Erith Council, not being prepared to accept this offer, have submitted alternative terms to the Bexley authority. At the last meeting of the Erith Council it was reported that the Highways Committee of the London County Council in connection with the suggested junction between the L.C.C. tramways at Abbey Wood and the District Council's trams, and the through running of the latter to Beresford Square, Woolwich, state that they were not at present prepared to make any arrangement. They suggested that the deputation should further interview them in three months' time, and that in the meantime the tramway officers of the respective Councils should keep in touch.

EXETER: *Officials' Salaries.*—At the last meeting of the Corporation an endeavour was made to have a recent recommendation of the Electric Lighting Committee, to increase the salaries of certain employees at the eletric lighting works, rescinded. The Chairman of the Electric Lighting Committee, however, defended the recommendation, and argued that, having good men, it was best to retain their services. The motion that the recommendation should be rescinded was lost by a large majority.

FARNHAM: *Overhead Wires.*—The Council is still discussing the question of consenting to the erection of overhead wires by the Farnham Electric Lighting Co. The Council are insisting upon a plan showing where it is proposed to erect poles, but the company state that until they have canvassed the district, and know where their consumers will be, they will be unable to prepare this.

FELTHAM: *Electrically-Driven Sewage Pumps.*—At the last meeting of the Urban District Council the Drainage Committee submitted a scheme for drainage by electric pumps, gravitating systems being unsuited to the level nature of the locality. The Committee recommended that Mr. Midgley Taylor, of Caxton House, Westminster, be employed to advise as to the best scheme for sewage disposal, including, if practicable, arrangements for street lighting by electricity. Notice has been received from the United Electric Supply Co. of their intention to apply for a Provisional Order to supply current in the Feltham and surrounding districts.

GLASGOW: *Tramways Accounts.*—At the last meeting of the Corporation the tramways accounts, which we abstracted in our issue for June 25th, were discussed. Mr. J. Macfarlane, Convener of the Tramways Committee, moved the adoption of the report, and gave a general *resumé* of the position of the undertaking. After a long discussion it was agreed to take back the report for further consideration as to how the Common Good item of the surplus should be disposed of.

HAMPTON WICK: *Electric Lighting.*—The Council has received notification from the United Electric Light & Traction Co. of their intention to apply for a Provisional Order to supply electricity within the Council's area. The Council has resolved to dissent formally.

HEYWOOD: *Joint Tramway Working.*—The Bury and Rochdale Corporations have hitherto worked the tramway system in Heywood as a joint concern, upon agreed terms. The Heywood Council is now pressing for a revision of these. A conference of representatives of the three authorities has been held, and there is every prospect of an agreement being come to.

HULL: *Electricity Accounts.*—The annual report and balance-sheet of the electric supply undertaking was presented to the Council last week. After charging all expenditure, and allowing £1,500 for switchboard renewals, the gross profit for the year amounted to £2,083 more than that of the previous year, notwithstanding that reductions in price took effect for the full year as against a half-year only for the corresponding period ended March, 1907. The gross revenue increased from £45,433 to £49,555, and, although the price of coal had been approximately 40 per cent. higher than during the previous year, the expenditure had risen but very slightly. In fact, the coal cost had dropped from 0·41d. to 0·39d. per unit. The sum of £1,069 has been added to the reserve fund.

ITALY: *Genoa Tramways.*—The following are the statistics of the electric tramways in Genoa and district for 1907:—Total length of lines, 89 miles; length of lines worked (131·355 kilomts), 82 miles. The car stock consists of motors, 230; trailers, 144; funicular, 4; omnibuses, 33; making a total of 411 vehicles. The distance run last year was 7,139,739 car miles, and the number of passengers carried was 52,027,355. The receipts amounted to £283,672, and the expenditure to £184,609, leaving a gross balance of £99,063.

Genoa-Busalla Electric Railway.—On October 10th, 1907, was announced the formation of a private company to construct an electric railway from Genoa to Busalla *via* San Pantaleo, Torazza, Busaletta, Crocetta d'Orero and Casella. The works for applying electric traction to this line are in course of construction by the Italian Westinghouse Co., and the central power station is being erected at the Chiappella Quarry, at the west end of the port of Genoa.

Savona: Electric Traction.—The State railway authorities have decided to convert to electric traction the branch railway line Savona-S. Giuaeppe. This conversion is rendered necessary by the mountainous state of this line. There is a probability of a company being formed with the object of constructing and running an electric tramway line from Savona to Vado.

KINGS LYNN: *Electricity Accounts.*—The accounts of the Electricity Department for the past year show a profit of £563, after providing £3,213 for interest and sinking fund.

LAUNCESTON (TASMANIA): *Proposed Tramways.*—A proposal is being made to form a local company for the construction of tramways in this town.

LLANDUDNO: *Generating Station Smoke Nuisance.*—At the Llandudno Petty Sessions last week, the District Council was summoned for creating a nuisance by allowing black smoke to be discharged from the chimney at the generating station. For the defence it was pointed out that the Council had done all they reasonably could to prevent a nuisance. Some months ago £300 were spent in fitting mechanical stokers to two boilers, and to a certain extent this had prevented the emission of black smoke. It was now proposed to fix similar apparatus to two more boilers. The Bench, however, made an order for the abatement of the nuisance.

LONDON: *London County Council Tramway Guide.*—The guide to the tramway system of the Council, which is now in preparation, will consist of (1) an alphabetical list of places of interest in London, together with, in the case of those which are accessible by tramway, an indication of the route by which they may be reached, and (2) a list of the various tramway routes, with route diagrams and particulars of the car service, &c. A number of photographs and other illustrations will also be included in the guide, which will be of octavo size and sold at 1d. per copy.

North London Tramways.—The electric tramcar service between Finsbury Park and Moorgate Street was inaugurated last week.

Lambeth: Tramway Speeds.—In reply to a communication from the Council that the speed of the electric trams in South Lambeth Road and Stockwell Road should not exceed 12 miles an hour, the Board of Trade have written that they see no reason to vary the maximum speed of 16 miles an hour, as there are no sharp curves or steep gradients on the route.

Kennington Tramway Brotherhood.—An appeal is made for contributions to make good the deficit of £350 upon the hall for meetings of the St. Mark's Tramway Brotherhood, which was opened at Kennington Oval this year. The hall has been designed mainly for use of men employed on the tramways. The membership of the brotherhood, the principles of which are the avoidance of betting, gambling, intemperance, &c., is now about 2,000.

Shoreditch: London Electric Power Bills.—A conference was held in the Town Hall last week of representatives of Borough Councils owning electricity undertakings. The object of the gathering was to consider the London and District Electric Supply Bill, and the London Electric Supply Bill, as amended in the House of Lords, and the decision of the Conference was that both Bills should be opposed by petition.

Streatham: Tramways.—A local landowner has made an offer to the London County Council to contribute £1,000 towards the cost of laying a tramway from the High Road, Streatham terminus, to the county boundary in Mitcham Lane.

LOUGHBOROUGH: *New Telephone Exchange.*—The National Telephone Co. has opened a new telephone exchange at Lutterworth.

LUTON: *Tramway Results.*—At a recent meeting of the Corporation, it was stated that the tramways, which were recently opened, and are being worked by Messrs. J. G. White & Co., under a lease from the Corporation, had been a great success up to the present.

MANCHESTER: *Damages against Corporation.*—The Corporation were sued at the Manchester Assizes on Monday by a Mrs. Ellisson for damages for the death of her husband. Mr. Ellisson, it appears, carried on business as pawnbroker and jeweller in Ducie Street, and it was claimed that his death was directly attributable to the after-effects of inhaling, in his bedroom, fumes arising from the fusing of an electric cable belonging to the Corporation. On the suggestion of Mr. Justice Bucknill, before whom the action was heard, the parties arrived at a settlement, the Corporation agreeing to pay £125 damages, and costs.

NEWCASTLE: *Tramway Receipts.*—During the week of the Royal Agricultural Show at Newcastle, the number of passengers carried upon the tramway system was 1,151,685, an increase of

Digitized by Google

314.899 over the corresponding week of last year, and the receipts amounted to £5,232, an increase of £1,423 over the corresponding week of last year. The average receipt per car mile for the week went up to 14·24, against 10·85 last year.

NOTTINGHAM: *Tramway Accounts.*—The annual report of the Tramway Manager states that the total income for the past year amounted to £153,745, and the expenditure, including sinking fund, interest, &c., amounted to £131,586. Of the balance, £17,000 have been contributed to the rates, the last instalment of £900 written off the cost of motor omnibuses, and the remaining £4,457 has been carried to reserve fund, which now amounts to £59,812. The number of passengers carried, viz., 34,411,860, showed an increase of 3,193,169 over the previous year, and the car miles run, viz., 3,299,283, show an increase of 567,631 over the previous twelve months. The average fare paid per passenger amounted to 1·05d., compared with 1·06d. for the previous year. The receipts per car mile dropped from 12·30d. to 11·18d., owing, to some extent, to the unsatisfactory results upon two new routes, including one to Trentbridge. The receipts upon these particular routes were 1·90d. per car mile less than the amount required to meet the charges for interest and sinking fund.

OLDHAM: *Electricity Accounts.*—At the last meeting of the Corporation, Alderman Bolton, in moving the adoption of the electricity accounts, said he had much pleasure in being able to say that there was a profit of £1,723, in spite of the fact that they had had to pay 1s. 4½d. per ton more for coal, which amounted to £1,230 during the year. They had also had to pay out of revenue £504 on account of boilers, and £511 on accounts of the water purifiers. With regard to next year, it was estimated that boiler repairs would entail a further expenditure of £800, that the water purifiers would involve a payment of a further £500, and that the assessment would be increased by £116. He also drew attention to the fact that the profit had been placed to reserve, and mentioned that at one time the undertaking had had a reserve of £10,000. Owing to the Local Government Board inspector, however, refusing to pass certain accounts out of revenue, this reserve fund had now dwindled down to nothing, and he hoped the Council would not ask the electricity Committee to pay a penny in relief of rates until they had a reserve of £50,000.

PENARTH: *Proposed Tramway Scheme.*—The District Council having communicated with the Local Government Board as to the legality of taking a poll in reference to the proposed tramways to Cardiff, has been referred to the district auditor.

RICHMOND: *Tramways.*—Sir Clifton Robinson has informed the Town Council that unless consent is given to the adoption of the overhead trolley system the Bill authorising the tramways in Kew Road and over Kew Bridge will be dropped. He intimated that in the light of recent experience the surface-contact system of traction was not one that the directors, on the ground of public safety alone, would be prepared to instal along so important a route.

SHEFFIELD: *Electric Lighting.*—At the last meeting of the Corporation Councillor Bennett, in an explanatory speech with reference to the accounts of the electric lighting undertaking, which we gave in our last issue, stated that the people who thought the undertaking should be making larger profits and contributing large sums to the relief of rates, did not realise the difficult competition which it had to face. In his opinion the progress of the undertaking had been satisfactory. The output had increased by more than 1,500,000 during the 12 months just ended, and in 10 years it had increased from under one million to over 8,500,000 units. Similarly, the revenue had increased by £9,067 during the year, and during the past 10 years it had increased by over 400 per cent. Further, the undertaking had paid to sinking fund in nine years £109,490, and in interest £189,997, or an average of £33,274 per annum. The profit for the current year would have been £7,280 instead of £4,796, but for the increased cost of coal. Councillor Bennett also drew attention to the works costs, namely, 0·57d. per unit sold, and pointed out that in his special report Sir Alexander Kennedy regarded an average cost of less than 0·6d. per unit sold as a very good one under all the circumstances. For the first time in the history of the undertaking the amount of energy sold for power purposes now exceeded that sold for lighting.

Tramway Employees' Appeal.—At the last meeting of the Corporation, it was decided to allow tramway employees to appeal to the committee in serious cases involving dismissal.

SOUTH SHIELDS: *Electricity Accounts.*—The accounts of the electricity undertaking for the year ending March 31st, 1908, show a revenue of £25,608, which is an increase of £2,907 over the previous year, whilst the expenditure amounted to £13,538, an increase of £4,140. The gross profit of £12,070, however, is a decrease of £1,232 compared with the previous year, and after meeting interest and sinking fund charges there is a net profit of £1,358, which the Electricity Committee recommend should be placed to reserve.

SUNDERLAND: *Electricity Accounts.*—The annual report of Mr. A. S. Blackman, the Corporation Electrical Engineer, shows that during the year ended March 31st the number of units generated was 10,933,825, or 1,625,482 over the figure for last year, whilst the number of units sold was 8,644,523, an excess of 1,067,000 over the number sold during the previous year. Power users have consumed 4,344,854 units, or 794,180 over last year. The number of consumers, as distinct from power users, now amounts to 1,224, an increase of 54 during the year, and the number of units sold for lighting purposes was 1,401,501, an increase of 142,450. The horse-power of motors installed is now 694,504, an increase of 91,509. The consumption for tramway purposes amounted to 1,834,026 units, an increase of 7,919. The capital expenditure during the year amounted to £57,467, bringing the total upon the undertaking to £403,295. This new capital expenditure had had the object of reducing the expenditure per kilowatt installed from £51 to £42 9s. The total costs, excluding capital charges, were 1·614d. per unit, a reduction of 0·052d. over the previous year. The total expenditure amounted to £35,224 and the revenue to £58,202. Capital charges, however, amounted to £24,886, thus leaving a debit balance of £1,908. In his report Mr. Blackman recommends the re-designing of the plant in order to make it up-to-date by the provision of new motor-driven pumps. The approximate cost of this he puts at £1,200, and considers it would be amply repaid in its effect upon the running costs. At last week's meeting of the Corporation some severe criticisms were made upon the results for the year, but it was decided to postpone serious discussion until the next meeting, when the chairman of the Electricity Committee, Mr. Alderman Bruce, will be present.

Telephone Tariff.—A number of telephone users in Sunderland, who are also land owners, have expressed their intention of not giving the company facilities for erecting poles upon their property except at greatly increased rents until the terms of the agreement now put before the telephone subscribers are modified.

SWANSEA: *Electricity Accounts.*—The net profit upon the electric lighting undertaking for the year ended March 31st amounts to £1,231, against £741 for the previous year. The gross profit was £10,246, from which interest and sinking fund, proportion of expenses on debenture bonds, and allowance of £64 due to defective meters, bad debts, &c., absorbed £8,950.

WADEBRIDGE: *Electric Lighting.*—A scheme of electric lighting has been placed before the Council by a syndicate, under which it is proposed to supply electricity by means of overhead wires fixed on poles about 30 ft. high. A representative of the syndicate attended the last meeting of the Council and explained the scheme, and it was agreed to sanction an application by the syndicate for a Provisional Order on the understanding that the work would be completed within twelve months, and that the Council should be entitled to purchase at the end of 15 years, or any other period which might be stipulated in the agreement.

WALSALL: *Tramway Supply.*—The Electricity Committee has provisionally approved an agreement for supplying the South Staffordshire Tramways (Lessee) Co., Ltd., with the current required for working the tramway lines leased to them, the price, subject to revision every three years, being 1½d. per unit, less 10 per cent. discount. The company is to take a minimum of 60,000 units per annum for the remainder of the term during which the lines are leased to them, viz., up to December 31st, 1921. The Local Authority is to bear the cost (estimated at £800) of laying the necessary cables.

WALTON-ON-NAZE: *Electricity Supply.*—Mr. H. R. Spence, of the Coast Development Co., which owns the pier at Walton, has notified the Council of his intention to apply to the Board of Trade for a Provisional Electric Lighting Order for the district.

WEYMOUTH: *Electricity Accounts.*—The third annual report of the Electricity Committee for the year ended March 31st shows that of the capital of £52,165 sanctioned, there has been expended £46,608. The number of consumers was 321, an increase of 59, whilst the total number of connection was equivalent to 23,893, 33 watt lamps, being an increase of 3,658 during the year. 176,644 units were sold for private lighting, 27,243 for power purposes, and 149,528 for public lighting, making a total of 353,415, an increase of 49,471. The gross receipts amounted to £5,672 and the gross expenditure to £2,727. Capital charges, &c., amounted to £3,043, leaving a deficiency on the year's working of £98, against £895 for the previous year.

WORCESTER: *Electric Signs on Lamp Posts.*—The Electricity Committee recommend that the street arc-lamp posts should be let for supporting electric light signs on such terms as the committee might approve. A number of members objected to the disfigurement of the district by such advertisements, and at the last meeting of the Corporation an amendment was carried authorising the committee to bring up a report showing what advertisements it was proposed to allow and the prices to be charged.

Electricity Accounts.—The Council has approved of the electricity accounts which we abstracted in our last issue.

WORKSOP: *Meter Rents.*—The Worksop Traders' Association has been informed by the Urban District Council that they cannot see their way to make any reduction at present in the charges for meter rents. At a meeting last week dissatisfaction was expressed with this decision, and the secretary was instructed to again write to the Council with regard to the matter.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

AUSTRALIA (SYDNEY).—Specifications are in preparation for a new storage battery at the municipal electricity works. The estimated cost is put at £22,500, exclusive of buildings.

According to the *Australian Mining Standard*, pending the introduction of a complete scheme to finance expenditure upon new telegraph and telephone work in the Commonwealth, it will be necessary to provide for the immediate appropriation of a sum of £32,345 for special work required during the year 1908–9.

BO'NESS.—The National Electric Construction Co. have reported to the Council with regard to extensions in the electricity works. They state that since the completion of the works the two original generators of 100 kw. capacity each have been heavily taxed, the peak load at times reaching 190 kw. In order to cope with present demands, it is proposed to instal a 300-kw. generating set, including a surface condenser and motor-driven air and circulating pumps; a new feeder panel and generator panel will be added to the switchboard, and a new feeder cable will be run to Kinneil and Grangepans. The estimated cost of extension is £6,000, and the Council has agreed to the scheme.

ECCLES.—A Local Government Board inquiry has been held into the application of the Corporation for sanction to borrow £16,270 for the extension of the electricity plant and mains.

FAREHAM.—A Local Government Board inquiry is to be held shortly in connection with the application of the Council for sanction to borrow £10,000 for electric lighting purposes.

FARNWORTH.—A Local Government Board inquiry was held last week into an application for sanction to borrow £7,000 for electric lighting. It was stated that the Council proposed to take a bulk supply from the Lancashire Power Co., with whom they have made very favourable terms upon an agreement to take 400,000 units per annum. Mr. R. B. Leach, the Electrical Engineer, explained to the inspector that the present works had never been designed for a motor load, and that the growth of such a load necessitated the expenditure proposed. Under the agreement with the Power Co. they would take energy at 10,000 volts three-phase and convert it themselves. The details of the expenditure proposed are as follows :—New engine house, stores, &c., £1,281; transforming plant, £2,500; switchboards, £450; extensions to battery, £300; new services, £700; contingencies, £100; floating expenditure, £383; whilst £1,284 have been spent in advance.

HEYWOOD.—A Local Government Board inquiry is to be held here into the Corporation's application for sanction to borrow £16,000 for extensions, &c., at the electricity supply works.

HORNSEY.—The Borough Council has authorised the extension of cable in Southwood Lawn Road at a cost of £43.

IPSWICH.—Tenders are invited for twelve months' supply of (1) rubber insulated wires for insulation work; (2) paper insulated lead-covered cables for laying underground; (3) bare copper trolley wire and bare copper strands. Particulars from the Chief Engineer and Manager, fee £1 1s. for each specification, and tenders by July 22nd.

KRUGERSDORP.—The Council will shortly be requiring additional electrical machinery.

NATAL.—The Natal Government is expected to be in the market for electrical plant during the next few months.

SPAIN.—The *Gaceta de Madrid* of June 28th states that tenders are invited for the supply to the Department of Posts and Telegraphs of 8,000 metres of aerial and subterranean telephone cable. Tenders will be opened 30 days from the above. Tenders must be accompanied by a deposit equal to 5 per cent. of the total value of the tender. Local representation is understood to be necessary. Copy of the form of tender, and the general and special conditions under which the contract will be granted, may be seen by British makers on application at the Commercial Intelligence Branch of the Board of Trade, 73 Basinghall Street, London, E.C.

Miscellaneous

LONDON: *London County Council.*—An expenditure not exceeding £400 is recommended by the Highways Committee for temporary turn-outs during the reconstruction of the tramways in Caledonian Road and Seven Sisters Road.

MANCHESTER.—Tenders are invited for the supply of special permanent-way track-work. Particulars from the General Manager (fee £2 2s., returnable) and tenders to the Chairman of the Tramways Committee, 55 Piccadilly, Manchester, by July 28th.

PORTSMOUTH.—The Tramways Committee invite tenders for six or twelve months' supply of best smokeless Welsh steam coal from August 13th, 1908. Particulars from the Engineer, Fratton Grove, and tenders to the Town Clerk by July 20th.

RAINHILL.—The Committee of Rainhill County Asylum invite tenders for an electrically-driven plunger pump. Particulars from the Clerk and tenders by July 23rd.

SIERRA LEONE.—Tenders are invited by the Municipal Corporation of Freetown for the lighting by electricity of the municipal buildings and streets by arc and incandescent lamps. Tenderers to quote price per 1,000 units. The exclusive right to supply electricity for private lighting for a period of at least 30 years will be granted to the successful tenderer. The right to instal electric tramways may also be acquired. Tenders to Town Clerk, Freetown, not later than August 22nd, 1908. The Corporation do not bind themselves to accept the lowest tender. The notice may be seen at the office of Messrs. Wilkinson & Broadbent, 4 Queen Street Place, E.C.

SUNDERLAND.—A main is to be extended to the Hendon Branch Library at a cost of £150.

Wiring

LONDON.

E.—The Trafalgar Square school is to be altered and reconstructed at a cost of £507. Architect, T. J. Bailey, L.C.C., Spring Gardens, S.W.

E.C.—Alterations and additions to the theatre at the Guildhall School of Music by the City Corporation

S.E.—The Vauxhall (L.C.C.) fire station is to be enlarged. Architect, W. E. Riley, L.C.C., Spring Gardens, S.W.

A factory is to be erected at Norwood for the trustees of the Stockwell Orphanage. Mr. R. Milnes, Stockwell Orphanage, Clapham Road, S.W.

W.C.—Premises in Holborn are to be adapted for trade classes, for L.C.C. (£5,460.) Architect, T. J. Bailey, L.C.C., Spring Gardens, S.W.

PROVINCES.

ALDERLEY EDGE.—Extensions to the David Lewis Colony (£4,500). Architect, Mr. George H. Willoughby, 3 York Street, Manchester.

BANGOR (CARNARVON).—Extensive additions to the Carnarvonshire and Anglesey Training College (£26,000). Architect, Mr. Hare, c/o Committee of Bangor Normal College.

BIRKENHEAD.—Council school at Hemingford. Estimated cost, £18,000. R. T. Jones, Secretary to Education Authority.

BLACKBURN.—The Blackburn District Co-operative Society are building a central boot and shoe establishment in Northgate.

BOURNEMOUTH.—Proposed municipal buildings at an estimated cost of £16,000.

BRENTFORD.—Additions to isolation hospital. Surveyor, J. W. Croxford, Clifden House, Boston Road, Brentford.

CARDIFF.—The County Council of Glamorgan has decided to erect a County Hall and offices.

The Wholesale Co-operative Society has acquired the old Cardiff Town Hall for conversion to a depôt.

CAMBRIDGE.—Extensions to the Baptist Church at Histon. Architects, George Baines & Son, 5 Clement's Inn, W.C.

CHELMSFORD.—New County Council education offices in Duke Street.

DARTFORD.—Council school at Crayford, Northend. Architect, C. E. Lancaster Parkinson, 44 Bedford Row, W.C.

Extensions to Bow Arrow Hospital by Rural District Council.

DURHAM.—New Council schools. A. J. Dawson, Clerk to Education Committee, Shire Hall, Durham.

DEVONPORT.—A County Council school at Camel's Head, providing 1,000 places. W. H. Crang, Secretary to Education Authority, Devonport.

ECCLES.—The Education Committee invite tenders for electric wiring at the new Clarendon Road Council school. Specifications, &c., from Mr. H. Lord, architect, 42 Deansgate, Manchester, and tenders by July 25th.

EVESHAM.—New public elementary school at Swan Lane. Plans by Worcester County Architect, Worcester.

FLINTSHIRE.—County Council school at Ewloe Green; estimated cost, £2,100. Director to Education Authority, Mr. J. Bevan Evans, M.A., Mold.

GLAMORGAN.—A County Council school at Llest. Dr. J. James, M.A., Director to Local Education Authority, Cardiff.

GOLDERS GREEN.—Church to seat 300. Messrs. F. W. Brodie and Arthur Waugh, of Golders Green, joint secretaries.

GOSPORT.—New school in Grove Road; estimated cost of £7,474. Architect, E. J. Trench, Upper King Street, Norwich.

GRAVESEND.—A Council school; estimated cost, £8,800. C. E. Hatten, Secretary to Local Education Authority, Gravesend.

HERTS.—County Council school at Cheshunt; estimated cost, £4,540. Director to Local Education Authority, A. R. S. Hallidie, Hertford.

HESWALL.—A new school for the Liverpool Juvenile Reformatory. Architect, H. Langton Beckwith, 3 Cook Street, Liverpool.

HULL.—New Wesleyan Church at Marfleet; estimated cost, £2,000.

Digitized by Google

ILFORD.—The Education Committee invite tenders for electric wiring and fittings for about 200 16-c.p. lamps at the Uphall School. Tenders to the Secretary by July 20th.

ILFRACOMBE.—Council elementary school. Builder, R. Pickett, Fore Street, Ilfracombe.

ILKLEY.—New Wesleyan Methodist Church at Ben Rhydding; estimated cost, £2,800.

KINGSTON-ON-THAMES.—Adaptation of "The Grove," Penrhyn Road, Kingston, for Education Committee's office accommodation; estimated cost, £400. Ramsay Nares, Secretary to Surrey Education Committee, Kingston.

LEEDS.—New Catholic College; estimated cost, £10,000. Architect, Mr. Benedict Williamson, c/o Rev. J. Kerr, S.J.

LEYTON.—New houses; estimated cost, £2,000. Builders, Messrs. Rowley Bros., of Tottenham. Architect, Herbert Riches, 3 Crooked Lane, King William Street, E.C.

LINCOLN.—Extensions to the City Diseases Hospital (£850). City Surveyor, Mr. R. A. MacBrair. Builder, Joseph M. Harrison, Melville Street, Lincoln.

MANCHESTER EXHIBITION.—The management of the Manchester Electrical Exhibition are open to receive tenders for wiring the buildings, but tenders will only be considered from contractors who are exhibitors. Particulars from the offices, 2 Queen Anne's Gate, Westminster.

MUSWELL HILL.—Blocks of residential flats. Architects, Messrs. Coleman & Holmes, Archway Road, Highgate.

NEWTON HEATH (LANCS).—Wesleyan Sunday School. Architects, Smith & Matley, 14 Ridgefield, Manchester. Builders, Young, Tinker & Young, Monsall Street, Queen's Road, Manchester.

NORTHWICH.—Free library (£4,500), and secondary school (£14,000). Sir John Brunner, M.P., donor.

NOTTINGHAM.—Alterations and additions to the School of Arts (£10,000). Particulars, Town Clerk.

OXFORD.—Reconstruction of Cattle Market (£5,000). Surveyor (Corporation), W. H. Castle.

RADCLIFF.—Municipal buildings (£13,500). Samuel Mills, Clerk to Urban District Council.

RAMSGATE.—New School (£13,000). E. B. Sharpley, secretary to Education Authority, Ramsgate.

RICHMOND.—Additions to the Town Hall. Alterations at Richmond Theatre. Architect, Mr. B. Crewe, 75 Shaftesbury Avenue, W.C.

ROCHDALE.—New schools, Church Army headquarters, and social club. Architects, Sykes & Evans, 7 Chapel Walks, Manchester.

SOUTHGATE (MIDDLESEX).—Additions to Colney Hatch Asylum (£450). Architect, W. E. Riley, L.C.C., Spring Gardens, S.W.

SWANSEA.—Forty-four working class dwellings. Borough Surveyor, Geo. Bell.

WAKEFIELD.—Wesleyan Sunday school and church (£2,200). Architects, Messrs. Garside & Pennington, Pontefract, Yorks.

WALTHAM ABBEY.—Messrs. F. Joyce & Co., Ltd., are to erect a factory at Waltham Abbey at a cost of £14,318. Builders, W. Lawrence & Son, Waltham Cross.

TENDERS RECEIVED AND ACCEPTED

AUSTRALIA.—The following were the tenders received for the new submarine cable connecting Tasmania with the main land. As we have already announced, the tender of Messrs. Siemens Bros. & Co., at £47,955, was accepted. The India Rubber, Gutta Percha & Telegraph Works Co., Ltd., £61,000; Norddeutsche Seekabelwerke, A. G., £58,000; the Société Industrial des Telephones, £87,200; the Telegraph Construction & Maintenance Co., Ltd., £56,000; W. T. Henleys Telegraph Works Co., Ltd., £97,000; and Siemens Bros. & Co., Ltd., £47,955.

BURNLEY.—The tender for alterations and additions to the offices at the electricity works has been placed with Mr. C. Brierley, of Fishpool.

CRAWLEY.—An order has been placed with the D.B. Battery Co. for a battery.

DERBY.—The tender of Messrs. E. Morley & Sons, at £43 15s., for fixing a weighbridge at the electric power station, has been accepted.

DUNDEE.—The tender of Messrs. Lowden Bros., for the electric wiring of the new Peters' Electrical Engineering Laboratory at the Dundee University College has been accepted at £49.

EDMONTON.—The Board of Guardians at the last meeting decided, on a report by Messrs. May & Hawes, of Westminster, to enter into a five years' agreement with the North Metropolitan Company for the supply of current for power and lighting to the new infirmary at 2½d. per unit.

EPSOM.—The Council has accepted the tender of Messrs. Dorset, at £17 18s. 9d., for placing telephone instruments at new pumping and fire stations at the waterworks.

FELIXSTOWE.—The D.P. Battery Co. has received an order for a battery of 110 cells of the L.S. 17 type, 224,000 watt hours, together with a Lancashire Dynamo Co.'s booster and accessories. The battery is under maintenance option.

HORNSEY.—The Borough Council has accepted the tender of Herbert Clarke, Ltd., for the supply of wharf slack for the electricity department; that of Charrington, Sells, Dale & Co., for hard steam coal (Ibstock); and the tender of Rickett, Smith & Co. for anthracite peas (Aberpergwym).

JOHANNESBURG.—An order for 200 street lamps, brackets, and fittings have been placed with the A.E.G. Electrical Co. of South Africa by the Johannesburg municipality. The tender of the Universal Electrical Manufacturing Co. has been accepted by the Corporation for the supply of 1,200 pairs of S.P. cut-outs, 1,200 sealing chambers, and 600 connectors. Five hundred Osram lamps are also being supplied by the General Electric Co.

KING'S LYNN.—The tender of Messrs. William Cory & Sons for 1,500 to 2,000 tons of Bestwood nut slack for the generating station at 9s. per ton has been accepted.

LONDON: *London County Council.*—With reference to the G.B. Surface Contact tramways, which are now in use between Aldgate and Bow, the Highways Committee report that in connection with the supply and fixing of magnet skate equipments upon these cars, it has been found that a single equipment, owing to large size of the Council's cars and other circumstances, do not give satisfactory results, and they recommend that these cars shall be fitted with a double equipment. The G.B. Surface Contact Co. offer to supply the equipment for 12 cars at £137 a car, and for the remainder of the 48 cars at £125 per car, and it is recommended that this offer shall be accepted.

The following tenders have been received for the manufacture, supply, and delivery of high and low tension switchgear for the second portion of the Greenwich generating station :—

Spagnoletti, Ltd. (recommended)	£2,212 0
Whipp & Bourne	2,349 11
Johnson & Phillips, Ltd.	2,403 2
The Electric Construction Co., Ltd. ...	2,646 6
British Westinghouse Electric & Manufacturing Co., Ltd.	2,864 0
A. Reyrolle & Co., Ltd.	3,700 0

The following tenders have been received for the supply of about 100,000 tons of coal required at the Greenwich generating station for the 12 months ending July 31st, 1909 :—

		s.	d.
Wm. Cory and Son, Ltd. (recommended)	100,000 tons	11	0
G. Owen and Co., Ltd.	100,000 ,,	11	1½

* Not in acordance with specification.

The Highways Committee recommend that the wiring and fitting for the electric lighting and power of the second portion of the Greenwich generating station should be carried out by the Tramways Department. It is recommended, however, that the wiring and fitting of the central car repair depôt should be done under contract.

The following tenders have been received for the heating and ventilating of the central car repair depôt :—

	£	s.	d.	£	s.	d.
Davidson and Co., Victoria Street, S.W.	1,447	10	0	1,520	0	0
The Standard Engineering Company, Queen Victoria Street, E.C. (recommended)	—			1,477	0	0
Musgrave and Co., Victoria Street, S.W.	2,158	13	1	—		
Jas. Keith and Blackman Company, Farringdon Avenue, E.C.	2,524	3	0	—		

The first set of figures represent the specified requirements, and the second set represent alternative schemes.

Poplar.—The following tenders have been received for an additional water-tube boiler at the electricity works :—

Stirling Boiler Co., Ltd. (*accepted*)	£2,225
Clarke, Chapman & Co., Ltd.	£2,573
Turner Bros.	£2,605
Babcock & Wilcox, Ltd.	£2,750
Davis & Co	£2,100

Digitized by Google

The tender of Messrs. Nicholls & Reynolds, at £737, has also been accepted for a new sub-station at Millwall. The structure will consist of a steel frame with hollow concrete block walls.

Stepney.—The Electricity Supply Committee has provisionally accepted the tender of the Reason Manufacturing Co., Ltd., at £175 for meters up to a capacity of 10 amperes. For meters above a capacity of 10 amperes, the tender of Messrs. Ferranti, Ltd., has been provisionally accepted at £328 10s. The following tender has been provisionally accepted for demand indicators, Reason Manufacturing Co., Ltd., £359 11s. For the annual supply of carbons the tender of the Sloan Electrical Co. has been provisionally accepted at £766 17s. 2d. For time switches the tender of Messrs. Venner & Co. has been provisionally accepted at £303 6s. 9d. In connection with the extension, now in progress, of street lighting by flame arc lamps, the Electricity Supply Committee has decided that 73 "Gilbert" magazine flame arc lamps be purchased from the Gilbert Arc Lamp Co., Ltd., at a cost not exceeding £8 10s. each, subject to the company making one or two slight modifications in the lamps as required by the Borough Electrical Engineer. For the supply of 70 switches and cut-outs, the tender of the Universal Electric Manufacturing Co. has been provisionally accepted at £1 3s. 3d. each.

MALTON (YORKS).—The Northern Counties Electricity Supply Co., at the request of the Council, has submitted a tender for street lighting. This tender, which is recommended for acceptance, contained a provision that on the nights of full moon, and two nights before and after, the street lamps shall not be lit. When the matter came before the Council it was unanimously decided to strike out this clause.

NEWCASTLE.—Messrs. R. McAlpine & Sons, of Glasgow, have been awarded the contract for the buildings in connection with the new power station of the Newcastle Electric Supply Co. The contract, which amounts to £60,000, involves the laying of a raft of concrete 5 ft. thick, upon piles, to form the foundation. The same firm have also in hand the formation of tunnels under the rivers Tyne and Weir, which are to be used for carrying cables.

RAWTENSTALL.—Messrs. Underwood Bros., of Dukinfield, have secured the contract for track work for reconstructing the tramways from steam to electric traction.

STOWMARKET.—The D.P. Battery Co. is supplying to the Suffolk Electricity Co. a battery of 130 cells of the company's L. 15 type, 1,800 watt hours, with a Lancashire Dynamo Co.'s booster and accessories. The battery is under maintenance option.

WEST AUSTRALIA: *Cottesloe.*—The D.P. Battery Co., Ltd., have received an order for the renewal of the Central Station Battery of 120 cells of their W.L. 9 type.

WALSALL.—The Electricity Committee have provisionally accepted the tender of T. Boston & Son, Ltd., Birmingham, for the supply of coal to the electricity department for one year; the Chloride Electric Storage Co., Ltd., for cleaning out the Hospital Street battery; Messrs. Jones & Horsfield, at £40, for covering new steam pipes at the generating station; and of Callender's Cable & Construction Co., Ltd., for laying a new feeder cable along Wednesbury Road Messrs. Baker & Co., of Rotherham, are to supply 60 car-wheel tyres at £16 2s. 6d. per ton, and the tender of Worthington & Co., at £22 17s., for the supply of line material, including mechanical ears, large and medium Brooklyn strains, and lignum vitæ strips has been accepted.

WILLESDEN.—The following tenders have been received for converting plant:—

Name.		
Crompton and Co., Ltd.	Motor generator	£713
Schorch	,, ,,	726 10s.
British Thomson Houston Co., Ltd.	,, ,,	735
Electric Construction Co., Ltd.	,, ,,	750
British Westinghouse Co., Ltd. (accepted)	Rotary converter	786
General Electric Co., Ltd	,, ,,	873
Siemens Bros. Dynamo Works, Ltd.	Motor generator	874
British Electric Plant Co., Ltd.	,, ,,	955
Bruce Peebles and Co., Ltd.	,, converter	1045
Mavor and Coulson, Ltd.	,, generator	1070
Johnson and Phillips, Ltd.	,, ,,	1104

The specification was for a 300 kw. set for converting alternating current at 3,000 volts to direct current at 480 volts. The tender accepted, as will be seen, was not the lowest, but the Council decided that it was the most economical having regard to the efficiency guarantee. The full-load efficiency in the case of the accepted tender was 94 per cent.

Rent of Cable.—In the Appeal Court last week the National Telephone Co. appealed against the decision of Mr. Justice Warrington that they are not entitled to lay a cable upon the bridge at Tonbridge Station except upon the payment of an annual rental of £30 and with the consent of the plaintiffs. We reported the action before Mr. Justice Warrington in our issue for April 16th, 1908, and the appeal against this decision was dismissed, with costs.

COMPANIES' MEETINGS AND REPORTS

CONSOLIDATED ELECTRICAL CO.—At the ordinary general meeting on Monday, Mr. H. Allen, Chairman, presiding, it was stated that the income for the past year amounted to £6,941 against £7,532 in the previous year, but this loss is more than accounted for by the fact that in the previous year the cash profit of over £1,200 was made by underwriting. The company has investments in the Private Wire & Telephone Installation Co. and the Anglo Portuguese Telephone Co., the latter of which has proved a remunerative investment. With regard to the former, however, it was pointed out that remunerative orders are becoming more and more difficult owing to the impossibility of small concerns competing successfully with powerful undertakings like the General Post Office and the National Telephone Co., and so their investments in this company, the Chairman remarked, must be regarded as a loss. The report and accounts were adopted.

DUBLIN UNITED TRAMWAYS CO.—Subject to final audit, the directors recommend the payment of dividends for the June half-year at the rate of 6 per cent. per annum on the preference shares and 6 per cent. per annum free of income tax on the ordinary shares, carrying forward £6,494, in addition to £7,494 unexpended of the sum provided last year for reconstruction and maintenance.

ELECTRIC CONSTRUCTION CO.—The report for the year ended May 31st, 1908, states that there has been a satisfactory increase in the volume of the company's business during that period. The amount of work in progress is considerably greater than at this time last year, including large power installations for India and the Midlands, in addition to machines of all sizes for home and abroad. The industry, however, is still suffering severely from over-production, and a small margin of profit only is obtainable. The net profit for the year, after payment of £10,250 for debenture interest, and crediting £5,000 as formely to depreciation account, is £5,932 6s. 9d. The sum brought forward from last year is £208 16s. 4d., and the amount available for distribution is therefore £6,141. The directors recommend that this profit be appropriated in payment of the dividend on the preference shares for the year ended May 31st, 1907, viz., £4,395, leaving a balance to be carried forward of £1,746. In view of the volume and character of the work in progress, the directors hope to declare about the end of December a dividend on the preference shares for the year ended May 31st last. In accordance with the arrangements described by the Chairman at the last annual general meeting, the directors have subscribed for £5,000 4½ per cent. preferred ordinary shares of the Madras Electric Tramways (1904), Ltd. A portion of the company's holding in the tramways has now been disposed of, and a depreciation of £2,000 on the realisation has been debited to general reserve fund. Your directors are pleased to report a marked improvement in the traffic receipts from the tramways during the past few months. The meeting will be held on Monday.

ELECTRICAL POWER STORAGE CO.—The directors' report and accounts to May 31st, 1908, show that the profit for the year, including the balance of £786 brought forward, is £4,860, out of which the directors recommend the payment of a dividend of 5 per cent. on the paid-up ordinary share capital, which will absorb £4,491, and leave £359 to be carried forward. The buildings, plant, tools, &c., have been maintained in thorough repair and condition at a cost of £3,046, which sum has been provided out of revenue. The debentures, amounting to £28,400, which appeared in the last balance sheet, have been redeemed. These have been replaced to the extent of £10,000 (part of an authorised issue of £30,000), thus reducing the debentures outstanding by £18,400. Owing to the fluctuations in the price of lead and other raw materials, together with the general depression in trade, the volume of business has somewhat decreased as compared with the previous year. The meeting is to-day.

HENDON ELECTRICITY SUPPLY CO.—At the first annual meeting of this company, Mr. C. F. Tufnell, who presided, referred to the good progress that had been made in the laying of mains and erection of sub-stations for the distribution of the bulk supply from the North Metropolitan Electric Power Supply Co. Pending the completion of these arrangements a temporary generating station was being worked. This supply was, however, not being carried on under statutory authority, but the permanent supply was to be given under the terms of the Hendon Electric Light Orders of 1889 and 1903. These Orders were originally in the name of Messrs. Crompton & Co., but an unopposed Bill was now before Parliament for their transference to the company.

LANCASHIRE POWER CONSTRUCTION CO.—The report for the past year states that the total liabilities amount to £53,765, and that a committee of shareholders has recommended the creation of £300,000 5 per cent. debenture stock, of which £150,000 will be offered to the shareholders at par, with a bonus of 50 per cent. in 4 per cent. income bonds. The stock will be secured by a specific first mortgage on all the debenture stock and shares of the Lancashire Power Co., and by a floating charge on the other assets and undertaking. There will also be created £100,000 non-cumulative 4 per cent. income bonds, ranking in priority to the present A and B shares. At the

Digitized by Google

meeting on Tuesday the report and accounts were adopted, and Mr. H. F. Parshall was appointed chairman of the company.

NATIONAL TELEPHONE CO.—The directors' report for the half-year ending June 30th, 1908, states that the income amounted to £1,452,826, as compared with £1,315,038 for the corresponding period of 1907, being an increase of £137,787. The working expenses amounted to £832,638, as compared with £749,760 for the corresponding period of 1907, being an increase of £82,878. The net result for the half-year (after deducting the Post Office royalties amounting to £139,546) is a profit balance of £480,641, as compared with £439,979 for the corresponding period of 1907, being an increase of £40,661. The rentals carried forward for unexpired terms of running contracts amount to £1,314,591, as compared with £1,210,117 at the corresponding period of 1907, being an increase of £104,474. Out of the available balance of £369,427, the Board recommend the payment for the half-year of a dividend at the rate of 6 per cent. per annum on the first and second preference shares, 5 per cent. per annum on the third preference shares, 6 per cent. per annum on the preferred stock, and 6 per cent. per annum on the deferred stock, less income tax in all cases. It is also proposed to transfer £140,000 to the reserve fund account, which now stands at £2,804,961, and to carry forward the balance of £10,677. The sume of £496,584 has been expended on capital account during the half-year in the erection of 16,761 additional exchange and private stations, and in the construction of underground works. The following three directors retire, and, being eligible, offer themselves for re-election viz., Mr. Charles Swain Agnew, the Right Hon. Lord Harris, and Sir Albert Kaye Rollit. The meeting will be held at Telephone House, Victoria Embankment, on Wednesday, July 23rd.

NORTH MELBOURNE ELECTRIC TRAMWAY & LIGHTING CO.—The accounts from October 11th, 1906, to September 30th, 1907, after providing for debenture interest, show a deficit of £8,897.

SIEMENS BROTHERS & CO.—The report for 1907 recommends a dividend of 4s. per share for the year, carrying forward £1,116. The sum of £3,500 has been written off the value of shares held.

YORKSHIRE ELECTRIC POWER CO.—An extraordinary general meeting was held at Leeds on Thursday, when the following resolution was passed:—"That the resolution passed at the extraordinary general meeting of shareholders of the company, held on the 26th day of September, 1905, authorising the borrowing of sums not exceeding £80,000 upon the terms therein mentioned, be rescinded so far as it authorises the borrowing of any further sums in excess of the sum of £40,000 already borrowed. And, further, that under the powers of and in exercise of the provisions contained in the Yorkshire Electric Power Act, 1901, and the Acts incorporated therewith, this special meeting orders that the directors be and they are hereby authorised to borrow a further sum or sums not exceeding in the whole £45,000, on mortgage of the company's undertaking, ranking after the £40,000 already advanced by Messrs. Barclay & Company, Limited, bearing interest at the rate of 6 per cent. per annum, and repayable with a bonus or premium at the rate of £5 per cent. after five years on six months' notice being given by the lender, or after two years on six months' notice being given by the company." Mr. A. G. Lupton, who was in the chair, stated that the new capital was required in connection with the supply at Brighouse and other places, and for the general development of the company. The directors had been giving very careful attention to the best way of raising the money, and had hoped to be able to issue debentures for the full amount authorised by their Act and so pay off the £40,000 which had been borrowed from the bank. On the advice of their brokers, however, they had come to the conclusion that the best plan was to obtain money by a second mortgage on the company and to ask the shareholders to find this capital, which would rank directly after the money owing to the bank. The money would be repayable in five years, if desired by the lenders, or at the option of the company any time after two years, repayment being made at the rate of £105 for every £100 invested, the rate of interest being 6 per cent. per annum paid half-yearly. With regard to the future prospects of the company, the chairman mentioned that, in addition to the Brighouse Corporation, which was arranging to close down its generating station and take the whole supply from the company, negotiations were also being carried on with the West Yorkshire Tramways Company for the supply to the tramways which it was supposed to run in Brighouse. Agreements had also been made to supply electrical energy at Hipperholme and to the Distributing Company which would supply the tramways at Ossett. Arrangements were also being made to construct an overhead main to supply in the Barnsley district. When all these were connected, a revenue of £18,000 per annum was anticipated, which would leave a considerable balance for dividend after meeting working expenses and interest.

Telegraph Traffic.—The Indo-European Co.'s lines between Tauris and Teheran were interrupted for one day only on the 6th inst. There is also one interruption to cable communication to report, viz., between Kwandang and Menada, both these places being in the Island of Celebes. But the island can, of course, still be reached by telegraph.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars net c.i.f. port of arrival quoted on Tuesday night was £59 to £59 10s. per ton. (Last week same price.)

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—A meeting of the creditors of the Kevan Electric Co. will be held on July 28th, at 35 Carey Street, Lincoln's Inn Fields, London, at 11.30 a.m.

The first meeting of creditors of T. A. Evans, trading as T. Evans & Co., electrical and mechanical engineers, Swansea, was held at the offices of the Swansea Official Receiver, on Thursday. Liabilities were put at £2,699, and assets at £68. The failure is attributed to speculation in a colliery undertaking. No creditors attended, and the official receiver remains trustee.

BERGMANN - ELEKTRIZITATS - WERKE AKT. - GES., BERLIN.—This company has for some time past been making experiments in connection with electric traction for main line railways; and, in order to be able to take advantage of the experience gained in this direction, has acquired the Westinghouse Company's patents in Germany.

CHANGE OF ADDRESS.—The Ebonestos Manufacturing Company inform us that owing to the largely increased demand for their moulded ebonestos insulators they have moved their works and offices to 127 Pomeroy Street, Old Kent Road, London, S.E. Telephone No., Deptford 887.

MESSRS. COWANS, LTD.—We are informed that Messrs. Cowans, Ltd., have now completed the reconstruction of their Salford works, which were destroyed by fire on January 21st last, and are now in a position to accept business for prompt delivery.

OUTING.—Some 200 employees of Simplex Conduits, Ltd., together with various managers of departments and branches, took part in a most successful outing to Matlock, Bath, on Saturday, July 4th. During the sports a challenge cup, presented by Mr. L. M. Waterhouse, was competed for.

PORTABLE VOLTMETERS.—Messrs. Elliott Bros. ask us to announce that they are in a position to supply portable indicating and recording voltmeters for direct-current and alternating-current circuits that comply with the requirements of the Board of Trade and local authorities for measuring the supply voltage on consumers' premises. These instruments have been approved for this purpose.

COMPANY MORTGAGES, &c.

COATBRIDGE & AIRDRIE ELECTRIC SUPPLY CO.—Particulars have been filed of a charge of £7,235, dated June 29th, secured upon the undertaking and all property of the company present and future, including benefits of certain agreements. The holders are the County of London Electric Supply Co., Ltd.

RHONDDA TRAMWAYS & ELECTRIC SUPPLY CO.—Particulars have been filed of £44,000 debentures created August 7th and secured by a trust deed dated August 8th, 1907. The property charged is the benefit of a trust deed, the benefit of an assignment of leasehold redemption policies dated March 16th, 1908, and the company's undertaking and property present and future, including uncalled capital. The trustees are Mr. C. A. Scott-Murray, director of the Sun Life Assurance Co., 63 Threadneedle Street, London, and Mr. L. B. Schlesinger, 21 Cornhill, London, E.C.

NEWCASTLE ELECTRIC SUPPLY CO.—A memorandum of satisfaction in full of mortgage debenture dated January 2nd, 1908, securing £300,000, has been filed at Somerset House.

STOTHERT & PITT.—Particulars have been filed of £50,000 second debentures created by a resolution on June 17th, 1908, the property charged is the company's undertaking and property present and future, including uncalled capital, subject to £250,000 prior debentures. There are no trustees. An issue of £30,000 debentures, part of the above series, has been registered.

SWITCHGEAR CO.—Particulars have been filed of mortgage and modifying deed, dated June 5th, 1908, of an issue of £3,000 debentures registered on August 24th, charged on £3,000 second debentures issued by Cowans, Ltd. The holders are Mr. E. A. M. Bindloss, 253 Monument Road, Birmingham, and Mrs. E. Clarke, Kanawha, Newton Abbot.

COWANS.—A memorandum of satisfaction to the extent of £2,000 of debenture stock, dated February 26th, 1908, securing £5,000, has been filed.

Municipal Tramways Association.—A meeting of the Lancashire and Cheshire Managers' Section of the Municipal Tramways Association was held at Bury last Friday. The meeting was held in the Council Chamber, where the visitors were welcomed by the Mayor (Alderman Collinge), who is also chairman of the local Tramways Committee. After the meeting, at which various topics relating to the management and working of tramways were discussed, the delegates visited the Bury car depot, and the works of Messrs. Mountain & Gibson, of Elton Fold.

PARLIAMENTARY INTELLIGENCE

HIGHGATE HILL TRAMWAYS.—The Bill promoted by the Highgate Hill Tramways Co. for the conversion of the line to electric traction and running powers over certain portions of the London County Council tramways, has now been formally withdrawn in consequence of the agreement to sell the undertaking to the London County Council.

TELEGRAPH CONSTRUCTION BILL.—Standing Committee C of the House of Commons had this Bill under consideration on Thursday. The Bill relates to the construction and maintenance of telegraph lines, and gives the Postmaster-General additional powers in the case of owners or occupiers refusing consent to the erection of telegraph and telephone lines upon their land; it also deals with flying wires over adjoining land roads, and the lopping of trees ostructing the telegraph lines. The Bill, with some amendments, was passed.

The Bill was read a third time in the House of Commons on Tuesday.

PATENTS AND DESIGNS BILL.—This Bill was considered in Committee of the House of Commons last week, was reported to the House without amendment, and was subsequently read a third time. The Bill only consists of one clause, and, as pointed out by the Attorney General, makes good a drafting mistake in the Patent Act of last year, the effect of which was to deprive litigants the right of appeal in cases where the patentee was alleged not to be the first inventor, where the invention was alleged not to be new, where there was alleged to be no subject matter for a patent, and in a whole group of similar important cases in connection with which the Government never intended to restrict the right of appeal.

PROGRESS OF ELECTRICAL BILLS.—The Lords' amendments to the Electric Lighting Provisional Order Confirmation Bills Nos. 1 and 2 were agreed to in the House of Commons on Wednesday last week. The Doncaster Corporation Bill and the Leeds Corporation Bill were read a third time in the House of Lords on Wednesday last week.

Electric Lighting Provisional Order Confirmation Bill 3, and Tramways Provisional Order Confirmation Bill No. 2, were read a second time in the House of Commons on Monday. The Wolverhampton Corporation Bill was read a third time in the House of Lords on Monday.

LONDON ELECTRIC POWER BILLS.—The London and District Electricity Supply Bill was read a third time in the House of Lords on Monday.

APPOINTMENTS AND PERSONAL NOTES

The Poplar Borough Council has increased the salary of Mr. J. H. Bowden, Borough Electrical Engineer, from £500 to £600 per annum as from July 1st, 1908.

Herr Robert Dahlander, Chief Engineer in the Electric Traction Department of the Swedish State Railways, has resigned in order to take over the management of the State Electricity Supply Works in Stockholm.

Mr. E. White, Superintendent of the Hilton Road generating station, has resigned.

Mr. J. Hebb, who was recently appointed canvassing engineer to the Derby electricity undertaking at 25s. with commission, will in future be paid £2 10s. per week inclusive.

The Journal.—The July number of the *Journal* of the Institution of Electrical Engineers (No. 190, Vol. xli.) contains the following Papers and reports of the discussions thereon :—"Electrical Power in Railway Goods Warehouses," by H. Henderson; "Electrical Power in Docks," by C. E. Taylor; "Fuse Phenomena," by Prof. Schwartz and W. H. M. James; "Artificial Load for Testing Electrical Generators," by R. K. Morcom and D. K. Morris; and "Rules of the Society of German Electrical Engineers," by W. P. Steinthal. Sir William Preece's lecture on "America Re-visited" is also included, and an original communication, entitled "The Potential of Partially-Insulated Systems in Relation to the Potential of Earth," by M. B. Field.

Electric Lifts with Push-button Control.—The electric lift at the new offices for the National Pension Fund for Nurses, at Buckingham Street, opened by the King and Queen recently, was installed by Archibald Smith & Stevens. It is fitted with push-button control, and requires no attendant. On each floor served is an ordinary button push, pressure of which will call the lift if it is not already in use. If the door is not locked after entering the cage the control circuit is interrupted and the cage cannot be moved. In the cage are placed a number of button pushes corresponding to the number of floors served, and pressure of any one button will send the cage to the corresponding floor. A stop-button is also provided to stop the cage if a wrong button has been pressed. When the lift is in use all the controlling buttons are dead, so interference with the passenger using the lift is impossible. No door can be unlocked or opened when the cage is not standing opposite that particular door. We understand Messrs. Archibald Smith & Stevens have also erected eight lifts worked on this principle at the new offices of the *Morning Post* newspaper, Strand.

MISCELLANEOUS CITY NOTES

BRITISH INSULATED & HELSBY CABLES.—The transfer books will be closed from July 18 to 25 inclusive, for the preparation of warrants for dividends on the preference shares. The warrants will be posted on July 30th.

COMPANIES STRUCK OFF REGISTER.—Among the companies which have been struck off the register under date July 10th is the New Electric Light Syndicate, Ltd., which was registered on December 12th, 1895.

The following companies will be struck off the register at the end of three months from July 10th, unless cause is shown to the contrary :—Cox Thermo-Electric Co., Ltd.; Simplex Electric Tramway Conduit Syndicate, Ltd.; Standard Dynamo & Motor Manufacturers Co., Ltd.; United Electric Wire & Telegraph Works, Ltd.

CITY & SOUTH LONDON RAILWAY CO.—The directors recommend a dividend at the rate of 1½ per cent. per annum on the ordinary shares for the June half-year. The dividend for the corresponding period of 1907 was 2½ per cent. £1.500 are carried to renewals fund, and £1,800 carried forward.

HESWALL DISTRICT POWER CO.—This company has just issued a prospectus inviting subscriptions to £30.000 £1 shares. Messrs. T. L. Miller, Wilson & Pegg are consulting engineers to the company, which has entered into an agreement with the Parish Council and the Wirral District Council, who are the ruling authorities, under which an application will be made to the Board of Trade for a Provisional Order. The District Council has the option of purchasing at the end of 21, 28, or 35 years.

MEXICAN TRAMWAYS CO.—A dividend of 4 per cent. per annum for the three months to June 30th has been declared.

NEWCASTLE-ON-TYNE ELECTRIC SUPPLY CO.—An interim dividend of 2½ per cent., less tax, has been declared on the ordinary shares for the June half-year.

TELEGRAPH CONSTRUCTION CO.—An interim dividend of 12s. per share is recommended.

THOMAS PARKER.—Owing to the increasing demand for Rees Roturbo pumping and other machinery, for which Thomas Parker, Ltd., holds the sole manufacturing right for Great Britain and Ireland, the present working capital of the company has been found to be inadequate for the increased business. Consequently a new company is being formed, entitled the Rees Roturbo Manufacturing Co., Ltd., which will take over the whole of the assets and liabilities of Thomas Parker, Ltd., and carry on the business as a going concern. The directors of Thomas Parker, Ltd., intended originally to transfer the business under the powers given them in the Memorandum and Articles of Association of the company, and at a meeting of shareholders in April this scheme was passed unanimously. Owing, however, to a judgment given in the High Court immediately after this meeting, the directors were advised that it would be necessary to proceed by a voluntary liquidation and a transfer by the liquidator under the 161st section of the Companies' Acts of 1862. The necessary meetings of shareholders have now been held, and the scheme has been passed, and the company is now in voluntary liquidation for the purpose of carrying out the scheme, in full accordance with the advice of counsel. In the meantime, the business will go on as usual.

UNITED RIVER PLATE TELEPHONE CO.—A final dividend of 5 per cent. on the ordinary shares, making 8 per cent. for the year, free of tax, is recommended. The amount carried forward is £4.904.

NEW PUBLICATIONS

"Journal" of the Institution of Electrical Engineers. July, No. 190, Vol. 41. (London : E. & F. N. Spon.) Price 5s.

"Handbook of Farm Buildings, Ponds, &c., and their Appurtenances." By Thomas Winder. With a chapter on the "Application of Electricity to Farming and Agriculture," by J. W. Beauchamp, Deputy Manager of the Sheffield Corporation Electric Supply Department. (Sheffield : Pawson and Brailsford.) Price 6s. 6d.

Arrangements for the Week.—The Institute of Marine Engineers is holding a meeting in the Congress Hall, at the Franco-British Exhibition on Saturday next, July 18th, at 7 p.m., when Mr. W. P. Durtnall will read a Paper on "The Generation and Electrical Transmission of Power for Main Propulsion and Speed Regulation."

Obituary.—We regret to have to announce the death, on Wednesday last week, of Lord Blythswood, at his residence, Blythswood House, Renfrewshire. Apart from his work in the social and political life of West Scotland, Lord Blythswood was one of the comparatively few members of the House of Lords greatly interested in science, and carried out a considerable amount of research work in connection with Röntgen rays, as well as experimenting in connection with physics, having a private laboratory of his own at Blythswood House. Glasgow University conferred an honorary degree upon him in recognition of his scientific work. His Lordship was born on February 22nd, 1857. The funeral took place on Saturday at Inchinnan Churchyard, near Glasgow.

SUMMARY

A fire occurred upon the City & South London Railway near Moorgate Street station on Thursday. An official inquiry was opened by the Board of Trade on Monday, at which Mr. P. V. McMahon, Electrical Engineer to the Company, expressed the opinion that the fire was not an electrical one. The inquiry was adjourned *sine die*. (Page 130.)

The following books are reviewed in this issue:—"Industrial Electrical Measuring Instruments," by K. Edgcumbe; "Modern Electrical Theory," by N. R. Campbell; and "Wireless Telephony," by E. Ruhmer (translation). (Page 131.)

An article on "Rail Corrugation" summarises a recent essay by the Belgian engineer, M. Lassalle, in which he suggests a connection between the characteristics of the series motor, which will set up a condition of alternate slip and roll, and this form of rail wear. As contributing to the effect, he shows that the normal load impressed by car-wheels upon the rail-heads approaches the elastic limit of the steel. (Page 132.)

The annual report and accounts of the Manchester Corporation Electricity Department records a considerable increase in the load and a reduction in the total expenses per unit sold as compared with last year, notwithstanding the increase in the price of coal. The figure now stands at 1·379d. per unit, with the inclusion of all capital charges. A surplus of £17,545 has been obtained on the year's working. (Page 133.)

In view of the opening of the section of the Midland Railway equipped on the single-phase system, a good deal of interest has been directed to the progress of the work on the London, Brighton and South Coast Railway, which was the first to decide upon this system. We are able to give a few notes on the form which the equipment will take. Considerable difficulties have had to be overcome owing to wide variations in the height of the overhead conductor enforced by local conditions, and the most elaborate precautions are being taken to minimise interference with neighbouring telegraph and telephone lines. (Page 134.)

In his annual statement in the House of Commons on Friday, the Postmaster-General said that the Government was determined that the telephone system should be placed upon a paying basis. With regard to complaints as to overcharging on the measured rate system, experience, he said, had shown this to be impossible. On the question of wireless telegraphy Mr. Buxton said he was glad that the relations between the Post Office and the Marconi Co. had entirely changed, and were now of a most friendly character. (Page 134.)

Digitized by Google

A STATEMENT sent by Mr. MILES WALKER, at the request of the Sub-committee on Symbols of the British Electrotechnical Commission, relates to the creation of a number of new symbols to represent physical quantities. It is proposed that the use of initial letters, such as "R" for resistance, "C" for current, &c., should be avoided, as such letters are not international. The substitution of entirely new signs is put forward as a way out of the difficulty, and some examples are given. It is further suggested that the name of the symbol should be the name of the unit represented. (Page 135.)

THE replies of Mr. C. M. SHAW to the discussion on his Paper on "The Reconstruction of an Electric Lighting Scheme," and of Mr. H. A. RATCLIFF to the discussion on his Paper on "The Standardising and Testing Department," both read at the Nottingham Convention of the Incorporated Municipal Electrical Association, are given in full. (Page 136.)

THE annual report of Mr. G. SCOTT RAM, his Majesty's Electrical Inspector of Factories and Workshops, reports that the increase in accidents due to electric causes reported under the Factories Acts is smaller than might be expected from the growth of the applications of electrical power in factories. A number of the accidents mentioned are due to easily preventable causes, of a nature that has been frequently commented upon in previous reports, and many are due to pure carelessness. In view of several fatal accidents that have occurred through faulty electric handlamps, Mr. Ram goes into the design of these in some detail, giving illustrations of lamps in which exposed metal work is liable to become "live" through accidental contact with conductors, and some better forms in which this risk is practically eliminated. Several fatal accidents with voltages in the neighbourhood of 250 are recorded, but it is noticeable that all these are on alternating-current circuits. Some interesting statistical tables are included. (Page 137.)

A SHORT note calls attention to rather an amusing aspect of the telephone difficulties in Paris. (Page 139.)

A VERY simple electrolytic prepayment meter has just been put on the market. The insertion of a coin lowers an electrode into a caustic soda solution. Current can then be drawn from the supply until the level of the liquid falls, on account of the electrolytic action, below that of the electrode, when a resistance is inserted in series with the consumers' lamps. The electrode can be immersed again by the insertion of another coin. The chief features of the meter are simplicity and low cost. (Page 140.)

A DESIGN for an arc-lamp standard for the streets in the City has been submitted to the Electrical Engineer to the City of London by a firm of iron-founders. The design includes no means for lowering the lamp, so that the use of a tower for cleaning and adjustment would be necessary. (Page 140.)

THE electrical equipment of the Stanningley Ironworks, near Leeds, includes the electrical driving of a great variety of machinery for general engineering work. The supply is taken from the mains of the Yorkshire Electric Power Co., and transformed down on the premises from 10,000 volts to 400 volts. There are over fifty motors, aggregating nearly 1,000 h.p., and vary in size from 2 to 140 h.p. each. (Page 141.)

OUR fourth illustrated article on matters of electrical interest at the Franco-British Exhibition, contains some further particulars of the electrical engineering exhibits, including some additions to the collective exhibit of the electric supply companies of London which have been made since our last description. An account is also given of the method of control employed for the electrical driving of the large newspaper press in the *Daily Mail* Pavilion. Some further notes of the power plant in the Exhibition will appear in our next issue. (Page 143.)

IN a Paper read before the Institute of Marine Engineers on Saturday by Mr. W. P. DURTNALL, the application of the "Hart-Durtnall" electrical power transmission system to main marine propulsion was dealt with. The author estimated the possible saving in necessary boiler capacity and coal consumption to be gained by utilising electrical transmission with polyphase induction motors, and described how different economical speeds could be obtained by variations in the number of effective poles of the motors. (Page 147.)

A LETTER from Mr. A. M. TAYLOR refutes some of the criticisms made on his Paper discussed at the Nottingham Convention of the Incorporated Municipal Electrical Association, and one from Mr. A. BENNIS relates to the relative advantages of certain types of automatic stokers referred to in the discussion on another Paper read at the Convention. (Page 148.)

NOTES are given under "Electrochemistry and Electrometallurgy" of an electrical method of maturing wines and spirits, and on experiments which are being conducted at Marseilles on the electrical stimulation of vegetable growth by current-carrying conductors buried in the ground. A new primary cell in which aluminium and magnesium electrodes are employed, and which, on addition of hydrogen peroxide will give an E.M.F. up to 1·7 to 2·1 volts is described. Other subjects dealt with are the electrolytic oxidation of copper and the electrolysis of pure hydrochloric acid. (Page 149.)

UNDER "Electrical Science," in the British and American section, is a note on the results of some investigations into the magnetic properties of the iron alloys known as "stalloy" and "lohys" iron. In the Continental section a method of obtaining a high-potential direct pulsating current from an induction coil with a Wehnelt interrupter is described. A Paper by C. TISSOT, referring to the composition of thermo-electric detectors for electromagnetic waves, is abstracted, and particulars of an automatic repeating ballistic galvanometer constructed by GUILLET are also given. (Page 149.)

SOME novelties in the way of telephone apparatus and branch switches are illustrated and described. (Page 150.)

A PATENT specification by the BRITISH THOMSON-HOUSTON CO., referring to a simple system of multiple-unit control, was published on Thursday last. The system consists in operating motor-controllers on the separate cars of a train by relays and an independent control circuit. An arrangement for equalising the load on alternating-current systems is described in a specification by J. S. PECK, and the BRITISH THOMSON-HOUSTON CO. have a second specification relating to the control of compensated series commutator motors. A specification by the ALLGEMEINE ELEKTRICITÄTS GES. describes a method of control for three-phase rolling-mill motors to enable the control to be effective at speeds considerably below the normal synchronous speed. The improvement of microphones by the substitution of hydrogen for air in the granule chamber is the object of a patent by C. E. EGNÉR and J. G. HOLMSTRÖM. Application for the amendment of a specification relating to induction furnaces has been received from the GRÖNDAL KJELLIN CO. Two patents of electrical interest expire during the current week; one of these is that for the well-known method of transformation from two- to three-phase devised by C. F. SCOTT, and the other relates to controllers for electric lifts and winches. (Page 151.)

BEFORE the Unopposed Committee of the House of Commons last week a long discussion took place in connection with a report by the Home Office and the Commissioner of Police upon the Metropolitan Electric Tramways Bill. The Bill proposes the construction of

Digitized by Google

a short extension of tramway in the Harrow Road, and the Commissioner of Police asked that temporary tramways should be on a level with the surface of the roadway; that the company should not be allowed to carry parcels; that the Commissioner should be authorised to call the attention of the Board of Trade to cases where the track is in a bad state of repair; and that he should have the use of the tramway standards for fixing directions for traffic, &c. The Committee were against the Commissioner on the first two points, but conceded the others. (Page 153.)

IN the House of Lords on Tuesday, the London United Tramways Bill, which provides for the construction of tramways over the new King Edward VII. bridge at Kew, was passed with a provision that the County Councils of Middlesex and Surrey shall have the right to decide whether the overhead or any other system of traction shall be adopted. (Page 153.)

THERE is a debit balance of £1,000 on the working of the Ayr electricity undertaking for the past year.—The annual report upon the Croydon Corporation Tramways for the year ended March 31st, 1908, shows a balance of £2,829 after providing for interest and sinking fund. The number of passengers carried was 16,277,318, an increase of 83,416 over the previous year. Complaint is made in the report of the high price charged by the Electricity Committee for the energy.—The Dundee Tramways Committee has decided to be its own insurers against third-party risks, and £1,000 per annum is to be set aside for this purpose.—The Hastings Corporation has agreed to Sunday trams on condition that the Sunday profits shall not be taken into consideration in fixing the price should the Corporation acquire the company's undertaking.—Alderman SMITH, the deputy chairman of the Liverpool Tramways Committee, brought a libel action this week against some other members of the City Council, but on Monday the jury decided that he had failed to prove malice.—There is a net profit of £888 upon the Bermondsey electricity undertaking for the past year after meeting interest and sinking fund.—The accounts of the Wolverhampton electricity undertaking show a net profit of £3,325 for the year ended March 31st, 1908.—The Yarmouth electricity accounts for the past year show a small deficit of £14. (Pages 155 to 157.)

THE Highways Committee of the London County Council recommend that tenders be invited for lighting Westminster Bridge by electricity.—Extensions to the public arc lighting in Swindon are contemplated at a cost of £1,180.—The York Electricity Committee invite tenders for electrical accessories.—A 900 kw. direct-current generator with Belliss engine is required by the Hull Corporation.—The Dewsbury Corporation requires a storage battery, reversible booster, switchgear, &c.—The Local Government Board has sanctioned a loan of £27,000 for extensions to the Ilford electricity undertaking.—For the information of wiring contractors we give particulars of a large number of buildings about to be erected in London and the provinces. (Pages 157 to 159.)

THE report of the City & South London Railway Company for the June half-year shows a gross profit of £47,536, and after making provision for debenture stock, interest, &c., there is a net balance of £32,999. A dividend of 1½ per cent. is recommended upon the ordinary stock.—The net profit for the year to March 31st of Messrs. Crompton & Co. amounts to £31,220. A five per cent. dividend is recommended.—The report of the Bombay Electric Supply & Tramways Company shows a balance available for distribution of £30,701.—The report of the East London Railway Co. states that a report has been prepared dealing with the question of converting the line to electric traction.—There is a net trading profit of £59,753 shown by the accounts of the General Electric Company for the past year. A dividend of 5 per cent. upon the ordinary shares is recommended.—Subscriptions have been invited for £100,000 five per cent. prior lien debenture stock of Edmundson's Electricity Corporation; for £125,000 ordinary £1 shares by the Malta Tramways Company; and for £500,000 4½ per cent. redeemable debenture stock by the Toronto Power Company.—Dividends are announced by the Bournemouth & Poole Electricity Supply Company, the St. James & Pall Mall Electric Light Company, and the County of London Electric Light Company. (Pages 159 to 161.)

THE Central Ireland Electric Power Bill was passed by the House of Commons Committee last week. The only opposition was by the Dublin and Alliance Gas Co., who opposed on the question of unfair competition, and called Mr. STEPHEN SELLON, who expressed the opinion that the scheme could not be financially sound. (Page 161.)

THE cars upon the G.B. Surface Contact system, which has been in experimental use in the Mile End Road, have been temporarily withdrawn, and a full report on the matter is to be placed before the next meeting of the London County Council. (Page 161.)

THE annual report of Mr. G. SCOTT RAM on the accidents due to electrical causes which he comes across in the course of his work as His Majesty's Electrical Inspector of Factories always contains matters of interest, and is valuable as making public results of experience with electrical apparatus of every shade of good and bad design, and revealing possible causes of easily preventible danger which might pass unsuspected. Last year the subject of badly constructed motor-starting gear was given particular attention, and in the latest report, published at some length in this issue, Mr. RAM deals more especially with faulty hand-lamps, and shows, by citing actual examples, how often there is a lack of proper precautions to prevent liability of exposed metal parts becoming live. The layman on reading the report will perhaps be a little apt to infer that anyone taking hold of one of such lamps will immediately drop down dead, and may clamour that electric hand-lamps *per se* are dangerous; but it must be realised that the purport of Mr. RAM'S report is to emphasise dangers which exist, although remote, and not to call attention to the obvious fact that for every hand-lamp which causes even a harmless shock, many millions have not only stood the rough use to which they are inevitably subjected, but prevented risks of even more serious kind by obviating the use of naked lights. The question may perhaps be asked whether it is really the right course to depend absolutely upon the excellence of construction of the lamp to prevent the possibility of the user being subjected to the voltage of the circuit, and this brings up again the vexed question of what is the lowest "dangerous" voltage. It may certainly be argued that a voltage, the use of which is perfectly justifiable for fixed installation work, may not be suitable for use with a lamp which is grasped in a man's hand. One possible way of avoiding such risk as exists on alternating circuits, and it is on alternating circuits that most of the "moderate voltage" accidents occur, is to take advantage of the economies of the low-voltage metal filament lamp, and instal transformers either for the whole group of lamps or at the plug from which the hand-lamp is supplied in order to step down the voltage to a value which is harmless, however great the leakage, and which enables high-efficiency lamps to be used with filaments thick and robust enough to stand hard usage.

Two decisions affecting tramways in the metropolitan area have been given by Parliamentary Committees this week which deserve attention. It is the practice of the Board of Trade and the Home Office to make individual reports upon all Bills which come before Parliament should the circumstances warrant it, and such reports have to be complied with unless very good reason is shown to the contrary. It is, of course, open to the promoters to oppose such reports, and thus it happened that a report by the Home Office, instigated by the Commissioner of Police, upon the Metropolitan Electric Tramways Bill was objected to before the Unopposed Committee of the House of Commons on Thursday, and, on the whole, there was good reason for this opposition. It appears that the Commissioner of Police has been asked to suggest further precautions in the interests of the general street traffic within the area of his jurisdiction, and he asked, among other things, that all temporary tramway rails should be laid level with the surface of the roadway, that the carrying of parcels should be prohibited, and that the Commissioner should have the right to call the attention of the Board of Trade to the condition of the tramway track. The fact that accidents occurred from the use of temporary raised rails during the reconstruction of the South London tramways is not sufficient reason for imposing upon tramway authorities the additional expense of laying what is in effect permanent track for purely temporary purposes, for, as several members of the Committee pointed out, it is the duty of other traffic using the road under these conditions to use proper care. Similarly the Committee, after having heard what is being done in other towns with regard to carrying parcels on tramways, refused to accede to the Commissioner's request. There can be no objection to the Commissioner having the power to call the attention of the Board of Trade to the condition of tramway track, for although this can already be done by the road authority or twenty ratepayers, neither party appears to take the matter very seriously. The other decision referred to was upon the London United Tramways Bill, in which a House of Lords Committee gave the Surrey and Middlesex County Councils the absolute right to determine whether an underground or overhead system of traction shall be used upon the new King Edward VII. bridge at Kew. This decision upholds the principle of local authorities' veto in connection with tramway matters which has been declaimed against on so many occasions, and had the company's suggestion of leaving the matter to the decision of the Board of Trade been accepted by the Committee a greater measure of fairness would have been given.

A GOOD deal has been made in those sections of the Press which imagine that their readers care more for sensationalism than dispassionate accuracy, of the fire which occurred last week on the City and South London Railway under circumstances reported in another column. The matter has been the subject of a Board of Trade inquiry by Col. YORKE and Mr. A. P. TROTTER, and we must withhold our opinion as to the actual cause of the fire until these gentlemen issue their report. From the evidence which has been heard there would seem to be room for doubt as to whether the cause of the fire was electrical or not, and further investigation appears to be required. The occurrence was nothing like so serious as has been made out, although the work of the Fire Brigade was, as is bound to be the case in a tunnel fire, attended with great difficulty. No one was hurt, and the statements as to panic among the passengers in the daily papers, as well as of the damage done, are gross exaggerations. The comments of the *Globe* on the inquiry are amusing. The railway is referred to as "a new method of travel," whereas it was opened in 1890, and all the witnesses at the inquiry had been for eighteen years in the employ of the company.

FIRE ON THE CITY AND SOUTH LONDON RAILWAY

ON Thursday evening, at about six o'clock, a fire occurred in the tunnel of the City and South London Railway, close to Moorgate Street Station, on the Bank Station side. It appears that as the driver of a Euston to Clapham Common train was approaching Moorgate Street from the northern side, he noticed a glow in the tunnel on the other side of the station, and by the time he had drawn up at the platform, he realised that some mishap had occurred. The attention of the stationmaster being drawn to the matter, instructions were at once given for the passengers to leave the train, and fortunately they all reached the surface without any danger or panic. By this time volumes of smoke had penetrated from the tunnel into the station, and the Fire Brigade was sent for. Considerable difficulty was experienced by the firemen in getting to the spot where the fire had occurred, owing to the smoke, and after endeavouring to deal with it from Moorgate Street Station end, an effort had to be made from the Bank Station, from which the firemen dragged the hose along the tunnel. It was not until eleven o'clock on Thursday night that the outbreak was finally overcome, when it was ascertained that a number of Jarrah wood sleepers and a disused signal box had been burned, but that no real serious injury had occurred to the permanent way; in fact, trains were again running on Friday.

An official inquiry was held by the Board of Trade on Monday, at the offices of the City and South London Railway Co., Moorgate Street, the presiding official being Lieut.-Col. Yorke, who was accompanied by Mr. A. P. Trotter, Electrical Adviser to the Board of Trade. Among those present were the General Manager of the Company, Mr. T. C. Jenkin, the Electrical Engineer to the Company, Mr. P. V. McMahon, and the Electrical Engineer of the City of London Corporation, Mr. A. A. Voysey. Evidence was first called from the officials at the Moorgate Street Station. The lift machinery attendant at Moorgate Street said that when he first noticed the fire, he fetched some sand and threw it on to two sleepers, the underside of which was on fire. This had little effect, however, and he informed the stationmaster what was going on. The stationmaster stated that when he arrived at the spot and threw sand upon the sleepers, the main cable became ignited. The current was then switched off. In answer to Mr. Trotter, the stationmaster protested against some statements of the daily papers as to the manner in which the passengers left the station. As a matter of fact, there was not the slightest sign of alarm amongst any of the passengers. The driver of the train coming from the north stated that he sometimes saw evidence of little fires on the line, but reported them to the stationmaster at the next station. Mr. P. V. McMahon, the Electrical Engineer to the Company, said that from the evidence, he was quite convinced that the fire was not of electrical origin. He did not think that the cables were the cause of the fire. With regard to the previous witness's evidence as to seeing little fires on the line, he said that sometimes light occurred at the base of an insulator near the sleeper, but this was soon remedied when the accumulation of carbon was brushed away. In the case of all recent repairs, wood sleepers have been replaced by slate slabs. There was no truth in the statements which had been made in the daily papers that the track for over one hundred yards leading into Moorgate Street Station had been destroyed. Mr. A. P. Trotter here remarked that when he visited the tunnel after the fire, he only found four sleepers badly charred. Mr. McMahon said that so far as the permanent way was concerned, they could have resumed running the trains half an hour after the outbreak was extinguished. The smoke and smell were no doubt largely due to the coating of the cables, and he agreed that it was important that the cable covering should be of non-inflammable material. He had formed a theory that possibly the fire had been caused by a spark from a shoe of one of the locomotives. Lieut.-Col. Yorke on this point raised the question as to why, if this was the cause, the sand did not put the fire out.

No further evidence was called, and the inquiry was adjourned *sine die*.

REVIEWS OF BOOKS

Industrial Electrical Measuring Instruments. By Kenelm Edgcumbe. 227 pp. 5½ in. by 8½ in. 126 illustrations. (London: Archibald Constable & Co.) 8s.

MR. EDGCUMBE has produced a very satisfactory book, which he is more or less right in claiming to be the first on the subject published in English. He writes of the various instruments as a maker speaking to users. The latter are assumed to be men in actual work, who need not be told a lot of preliminary theory and history, but are accustomed to use instruments every day. Such men, however, will always allow that a maker must be able to tell them a good deal about those that they use already and a good deal more about those of which they have not had practical experience. The why and wherefore is given to a reasonable extent in plain words; in alternating current instruments even, mathematics are cut down to a minimum, and the few vector diagrams are so simply put that, instead of irritating, they will rather serve to reconcile to their use those who are not accustomed to them, a consummation devoutly to be wished. There are forty pages of preliminary and general matter. The remarks on accuracy are good reading for any instrument user, and the table of the accuracy which may be expected from various types of instrument is a conservative one, as it should be. Constructional details such as springs, pivots, shunts, winding, and damping, are well and shortly dealt with. The various types of instruments, ammeters, volt-meters, watt-meters, ohm-meters, galvanometers, and dynamometers, are described and discussed. It would have been easy to have filled up the book with illustrations of these, from various manufacturers' catalogues, and to have made a far more pretentious volume, without in any way increasing its value. Mr. Edgcumbe has, however, adopted the much wiser course of giving no illustrations of the outside of any instrument; he has confined himself to diagrams of the various types which will apply to all makes alike, and has dealt solely with the principles common to all when dealing with a type made by more than one manufacturer. At the same time the reasons for sundry little details and precautions are given which, while well-known to makers, are liable to be overlooked by users when buying instruments. Several little points in their use are also mentioned, which it is convenient to have all in one book instead of scattered in various papers.

Pyrometers are barely within the scope of the book, and the cymometer is distinctly outside it. The oscillograph—well, one thinks of it as a laboratory instrument, and yet it is quite rightly included, as it is to a great extent, and should be still more, an industrial one.

Mr. Edgcumbe has been very successful in sinking, though in no way concealing, the fact that he is himself a manufacturer, and although he naturally mentions some of his own special ones with the rest, his book distinctly deals with instruments, and not with particular makes of them.

Modern Electrical Theory. By Norman R. Campbell. 332 pages, 5¼ in. by 8½ in.; 32 illustrations. Cambridge Physical Series. (Cambridge: The University Press.) Price 7s. 6d. net

THE rapid accumulation of experimental facts and of speculations in the domain of electricity and optics during the past ten years have made it exceedingly difficult for anyone but the professional expert to obtain anything like a comprehensive view of modern electrical theory. The books that have been published hitherto, at least in this country, are either of a more or less popular nature, or deal only with special branches, such as conduction through gases or radio-activity.

Mr. Campbell's work is, we believe, the first serious attempt "to expound the subject in its logical order, to analyse the arguments by which the various phenomena are correlated, to draw special attention to the assumptions that are made, and to show which of these assumptions are fundamental in the modern theory of electricity and which may be expected to be abandoned in this further progress of investigation." To accomplish this within the space of about three hundred pages, considering the wide range of phenomena to which the electron theory has been applied, was no light task; great condensation was necessary, and has been attained chiefly by omitting detailed descriptions of experiments and lengthy mathematical investigations. These details, however, can easily be filled in by the reader, as references are given at the end of each chapter to all the most important special treatises and original papers. The conception of Faraday tubes, developed with such success by J. J. Thomson, is utilised throughout, and is briefly explained in the first chapter. In the second chapter the ordinary electromagnetic theory is explained. It was the complete failure of this theory to explain certain optical phenomena, *e.g.*, magnetic rotation, which led H. A. Lorentz, thirty years ago, to the conception of electrons.

Succeeding chapters deal with the modern electron theory, and discuss the phenomena of magnetism, thermal and electrical conductivity, conduction through gases, radioactivity, and the constitution of the atom. The last chapter is devoted to the laws of electromagnetism, and contains an exceedingly good *résumé* of our knowledge of the optics of moving systems.

It is a book that should be read by all students of physical science; those who desire merely a good general knowledge of recent developments in electricity will find that it contains all that is essential; while those who wish to specialise will find it an excellent introduction and guide.

Wireless Telephony. By Ernst Ruhmer; translated by J. E. Murray, D.Sc. 224 pp. 8¾ ins. by 6 ins. 145 illustrations. (London: Crosby, Lockwood & Sons.) 10s. 6d. net.

RUHMER'S "Drahtlose Telephonie," which was published in Leipzig about a year ago, has as its chief characteristic the fact that it is the only volume extant devoted entirely to the art of telephony without intercommunicating wires. When it appeared in its original tongue, the book was a small one; but this English edition is, strange to say, a comparatively bulky volume. The contrast is due not so much to an appendix, or to publishers' advertisements, as to the employment of very thick glazed paper, and to prodigal indulgence in large diagrams. For instance, whole pages are, on occasion, given up to absurdly simple line drawings, and other pages are occupied by pictures of buildings or barges—beautiful when regarded as samples of half-tone blocks—with a relatively infinitesimal piece of wireless telephone apparatus in the field of view. This sumptuousness has caused the book to appear at what may be considered as rather a high price for the amount of information conveyed.

The first part of the work is rather more than a third of the whole, and is devoted to what is called photo-telephony, that is, telephony by means of beams of light. As is well-known, photo-telephony is based on the fact that the electrical resistance of selenium varies with the intensity of the light falling upon it. Bell and Tainter are notable names in the inception of photo-telephony, but Ruhmer himself, the present author, has in recent years improved the sensitive apparatus, has brought into use the speaking arc, and has thus extended the range of light-telephony to as far as 2 or 3 miles. All this is set forth in detail, and is of considerable scientific interest, though of but small technical import.

Digitized by Google

The next part of the work deals with wireless telephony of the purely electrical variety. First is described the "induction telephony," such as was carried out by Preece and Gavey between long parallel horizontal wire circuits closed through the earth. Then comes a description of spark telephony. Here are set out some of the various methods that have been proposed for producing streams of sparks of rapidity great enough to transmit sound waves by their variations of intensity. Some good oscillograph diagrams are given, but the general descriptions are very sketchy. About 50 pages are devoted to arc methods of wireless telephony; and the summary, here given by the author, of the work that has been done by various experimenters is a very just one, but not a very instructive one. The author makes an attempt to discriminate between the true singing arc (called by him the *pure* Duddell phenomenon) and the interrupted or screeching arc (the *impure* Duddell phenomenon). In the former, the current through the arc is practically sinusoidal, and, at its lowest value barely reaches zero value; in the latter the arc current is zero for an appreciable fraction of every period, and is thus, in the author's opinion, really of the character of a spark discharge in which a series of damped wave trains follow one another with great rapidity, but in which the sparking rate is in no way directly related to the frequency of the oscillations produced at each spark. The reader will find, we fear, that the author's explanations of these very complex phenomena, are often lacking in clearness; intelligibility is too often sacrificed to brevity. Nevertheless, the book is interesting and topical.

RAIL CORRUGATION

A RECENT number of the *Bulletin* of the "Association des Ingenieurs Electriciens sortis de l'Institut Electrotechnique Montefiore" (Liége), contains a study by M. Lassalle of rail corrugation which puts into a definite form certain theories of the causes of rail corrugation, and endeavours, by a quantitative analysis of the conditions, to show that the suggested causes are competent to produce the observed effect. One feature which distinguishes M. Lassalle's work from that of many theorisers on the subject is that it offers an explanation of the prevalence of corrugation on electric tramways as compared with their comparative rarity on railways and tramways worked in other ways.

Considering a stationary car of 10 tons weight carried by four wheels of 75 cm. diameter on rails weighing 43 kgs. per metre, and having a table 4 cms. wide, the author shows that the maximum compressive stress on the rail-head is 26 kgs./mm.^{2}, and as the elastic limit in compression of rail steel is from 30 to 35 kgs./mm.^{2}, it is reasonable to suppose that a running car will frequently stress the rail heads beyond the elastic limit, and produce permanent deformation, especially if the pressures between rail and wheel change suddenly producing shocks or incipient blows, or if abrasion occurs. How shocks and abrasion competent to produce deformation of an undulating character, or corrugations, may arise, the author seeks to show by an argument which is outlined below. Consider a car in motion upon a straight level track, provided with a series motor driving each axle, and let all the conditions be symmetrical, loads equally distributed, wheel diameters equal, motors exactly similar, ideal conditions, in short. Let the car be running at a uniform speed, then the motor or driving couple and the resistance couple are in equilibrium on each axle, this couple corresponding to a point on the torque speed characteristic of the motor for the controller notch in use, *i.e.*, for the voltage supply and the amount of resistance in the motor circuit. Now if the controller is moved to the next higher speed notch the motors will accelerate and reach a higher steady speed corresponding to a point on another torque speed curve, and assuming proper adjustment of the rheostat, the change will be smooth. But if the controller is moved over, say, three notches without pausing to let the motors attain their steady speed for each step, the motor couple will rise suddenly, and may produce wheel slipping when the resistance couple will fall sharply by the difference between the coefficient of adhesion and the coefficient of sliding friction, and the velocity of the revolving masses will increase, whilst the motor couple diminishes until it becomes less than the resistance couple due to the sliding friction. As soon as this occurs slipping ceases and adhesion recommences, whilst the motor current and couple again increase sharply, and slipping may be repeated. There may be several alternations of slipping and adhesion due to too great a movement of the controller before a new condition of equilibrium is reached, and the periods of these alternations will be very short. Whilst slipping the wheels abrade and wear the rails. The number of alternations, and therefore of successive abrasions, will depend upon the value of the coefficients of adhesion and of sliding friction, the forms of the motor characteristics and the amount of controller movement. The change from adhesion to slip and *vice versâ* will be sudden.

If corrugation may be produced in this way under the ideally symmetrical conditions postulated, it is evident that irregularities in the track, in the distribution of weight upon the car wheels, and other of the conditions may conduce to it. M. Lassalle proceeds to consider the case of curves where it is evident that alternate skid or slip and roll must occur, and also the effect of braking where excessive brake block pressure may produce intermittent skidding.

That corrugation is produced by such alternations of slip and roll or skid and roll has been suggested by several engineers during the discussion, which has been in progress for several years, and various causes of such alternations have been suggested. M. Lassalle, we believe, is the first to point out the possible connection between the characteristics of the series motor, coupled with the other conditions, and this troublesome form of rail wear, and thereby he may have found the answer to the rather puzzling question why corrugation is so distinctively (though not exclusively) a disease of electric traction. The suggestion is worth following up, and should not be difficult of experimental proof.

It is worthy of note that Professor Carus-Wilson, in the Paper read before the Tramway and Light Railways Association Congress on July 10th, asserts that corrugation is caused by alternate skid and roll, which he attributes to a particular combination of circumstances connected with wheel and rail wear. (It should be explained that "skid" means the condition that the wheel is revolving at a slower rate than that due to the velocity of the car, and "slip" means the condition that the wheel is revolving at a quicker rate than that due to the velocity of the car.)

Professor Silvanus Thompson said at the British Association meeting last year, in reference to corrugation, that "a periodic effect pointed to a periodic cause." The alternations suggested are necessarily periodic. But it is evident that the skid and roll or slip and roll may be set up by various means, and it is a merit of M. Lassalle's work that he discusses several in a quantitative manner which is worth study. Professor Carus-Wilson has hit upon one which does not seem to have occurred to M. Lassalle, but he will probably readily admit the possibility of others.

The question of hardness of rail is slightly touched on in the paper, to show that the normal loads, approximate to the compressive elastic limit of rail steel, and evidently the harder the steel the more resistance it will offer to the corrugating tendency.

Waves leave ripples in the sand, but wear the granite smooth.

MANCHESTER ELECTRICITY SUPPLY ACCOUNTS

THE following particulars of extensions and alterations to the plant of the Manchester Corporation are recorded in the annual report which accompanies the accounts for the year ended March 31st last.

Dickinson Street Generating Station.—Messrs. Bruce Peebles have satisfactorily completed their contract for the installation of three 1,500 kw. motor convertor units at the Dickinson Street sub-station. Negotiations between the department on the one hand and Messrs. Parsons and Messrs. Siemens on the other hand have been concluded, and arrangements made for satisfactorily carrying out the terms of the contract in regard to the two 750 kw. turbo-generators. A contract has been placed with Messrs. Richardson-Westgarth & Company for the installation of two Contraflo surface condensing plants in conjunction with the Musgrave engines, in place of the existing Körting condensers.

Bloom Street Generating Station.—The alterations to the flywheels on Nos. 1 and 2 Musgrave engines have been successfully completed. It is expected that similar operations on Nos. 3 and 4 engines will be carried through this summer. An agreement has been entered into with the Rochdale Canal Company in respect of the use of the canal water for condensing purposes, and the necessary works to carry this agreement into effect have been commenced.

Stuart Street Generating Station.—The contract for the installation of a 6,000 kw. Willans-Siemens three-phase turbo-alternator complete with Richardson-Westgarth condensing plant, which was entrusted to the first-named firm, has been carried to a successful conclusion. Considerable alterations and extensions to the high-tension switchgear have also been carried out by Messrs. Ferranti, Ltd., with good results. Further contracts are pending in respect of additional water-tube boiler, cooling towers, high-tension switchgear, pipework, and a second 6,000 kw. turbo-alternator.

A large number of sub-stations have been put down on consumers' premises, especially in the case of large manufacturing works, and nearly 20 miles of new mains have been laid during the year, bringing the total mileage of mains up to 338.

The total number of units generated and sold as compared with the previous year are given below.

	Year ended Mar. 31, 1907.	Year ended Mar. 31, 1908.
Units sold for private purposes ...	22,686,508	33,826,430
,, public lamps ...	91,938	98,818
,, traction	24,786,457	29,511,840
Total units sold	**47,564,903**	**63,437,088**
Units used on works	3,796,709	3,879,683
Units used in distribution or unaccounted for	11,695 302	15,436,218
Total units generated	63,056,914	82,752,989

No distinction is made between units sold for lighting or power as in previous reports, so that it is not possible to put into figures the relative increase of the two services.

The maximum supply demanded and corresponding load factors are given below.

	Max. demand.	Load factor.
Lighting and power ...	18,233 kw.	21·15 per cent.
Traction	10,288 ,,	32·8 ,,
Total	28,521 kw.	25·3 per cent.

The following table gives a summary of the average costs expressed in pence per unit sold, compared with the previous year:—

COST PER UNIT SOLD.

	Year ended Mar. 31, 1907.	Year ended Mar. 31, 1908.
Generating costs—		
Coal	0·213d.	0·247d.
Oil, waste, water and stores ...	0·028	0·029
Salaries and wages	0·081	0·064
Repairs and maintenance	0·076	0·066
Total generating costs	0·398	0·406
Distributing costs—		
Salaries and wages	0·066	0·065
Repairs, maintenance, &c.... ...	0·076	0·056
Total distribution costs ...	0·142	0·121
Total works costs	**0·540**	**0·527**
Management charges, &c.—		
Rent, rates, and taxes	0·137	0·109
Salaries and wages	0·035	0·030
Insurance, law, Parliamentary and special charges	0·006	0·006
Miscellaneous	0·013	0·007
	0·191	0·152
Total costs, excluding capital charges	**0·731d.**	**0·679d.**
Interest	0·333	0·260
Sinking fund and repayment of loans	0·351	0·282
Renewals suspense account	0·202	0·151
Applied in extension of works where borrowing powers are not granted (wages of permanent employees engaged on capital account)	0·012	0·007
Total costs, including capital charges	**1·629d.**	**1·379d.**

The total working expenses as analysed above amounted to £179,358, and the receipts from all sources were £385,024. Of the balance thus given, interest and sinking fund absorbed £68,855 and £77,268 respectively. £10,000 was carried to renewals expense account, and £1,998 was applied in extension of works where borrowing powers are not granted (wages of permanent employees employed on capital account), so that the final result was a surplus of £17,545, of which £10,000 was paid over in aid of rates, and the remainder carried to reserve. The costs of generation given above are, of course, averages for the three stations.

The following table shows the capital expenditure as at March 31st, 1908:—

Dickinson Street Generating Station—	
To land (including law charges incidental to acquisition)	£47,546
,, Buildings	51,755
,, Machinery and switchboards	172,315
Bloom Street Generating Station—	
To land (including law charges incidental to acquisition)	15,083
,, Buildings	57,878
,, Machinery and switchboards	127,330
Stuart Street Generating Station—	
To land (including law charges incidental to acquisition)	9,982
,, Buildings	210,832
,, Machinery and switchboards	327,610
To Stuart Street Railway	81,380
,, Distributing stations	326,906
,, Mains	889,468
,, Meters	57,306
,, Motors	26,371
,, Instruments	3,446

British Trade Correspondents in Canada.—The President of the Board of Trade has appointed Mr. R. Grigg, who recently completed a Commercial Mission in Canada and Newfoundland for the Advisory Committee to the Board of Trade on Commercial Intelligence, as H.M. Trade Commissioner in Canada. He has also appointed the following gentlemen as local trade correspondents in Canada:—Mr. W. J. Davidson, Vancouver; Mr. J. J. Shallcross, Victoria; Mr. J. Appleton, Winnipeg; Mr W. E. Anderson, St. John, New Brunswick; Mr. G. B. Ramsey, Quebec; Mr. A. T. Weldon, Halifax, Nova Scotia. It is possible that some further appointments of local correspondents may be made in Canada. The local Trade Correspondent in Newfoundland is Mr. H. W. le Messurier.

ELECTRIC TRACTION ON THE BRIGHTON RAILWAY

THE following particulars of the electrical working which will shortly be inaugurated on the suburban lines of the London Brighton & South Coast Railway are taken from a souvenir what was issued in connection with the formal opening of the reconstructed Victoria Station. The station has been designed to separate the main line and suburban traffic as much as possible, and at the south end of the eastern side offices is the electric switch cabin, to be brought into use when electric trains are running. The section of the line at present being electrified extends from Victoria to London Bridge, a distance of nearly nine miles, equalling approximately 23 miles of single line. In Victoria Station five platform and two through lines, and in London Bridge Station six platform lines are being electrically equipped.

The improved service contemplated will require seven working trains and one spare one, each train comprising two third-class motor coaches with luggage and motorman's compartments, each equipped with four 125 h.p. motors. The motor coaches form the first and last coach of a standard three-coach train, the middle one being a first-class trailer coach. It is proposed to give a ten minutes' service throughout the day; the time occupied by a journey from Victoria to London Bridge or *vice versa* will be 25 minutes including stops, as compared with 36 minutes as at present required by the steam trains. The total seating capacity of each three-coach train is 188. Great care has been devoted to the comfort of passengers, and contrary to the American practice of adopting coaches of the tramcar type with end doors, which have been used on the underground railways and which have proved draughty and inconvenient, a modified form of side-entrance compartment coach has been designed, so that in the case of any one compartment being full, passengers can pass into the next without having to leave the carriage, this arrangement giving greater convenience to passengers and saving time at the stations. Ample rack accommodation is provided for small parcels and hand luggage, and particular attention has been devoted to simple, but effective, decoration, and efficient and abundant lighting. The coaches are painted in the new London Brighton & South Coast colour, the bodies being 60 ft. in length and 9 ft. in width, with lofty and well-ventilated compartments. The electrical equipment on the motor coaches is so arranged that passengers cannot under any circumstances have access to any high-tension apparatus, which, indeed, is only accessible to the railway staff when the energy is cut off and all high-tension connections connected to earth, and thus rendered absolutely safe.

As regards the electrical equipment of the line, the overhead conductor which conveys electrical energy to the motors consists of a heavy grooved solid wire, ½ in. in diameter, which is supported at every few feet by means of dropper wires suspended from stranded steel catenary cables, which are in turn suspended from massive porcelain insulators through a double insulation which has been tested to ten times the working pressure. The insulators are supported upon specially designed steel structures. Due to the constantly varying nature of the line on this section, a very great number of different types of support had to be designed, the strength of these having been calculated on a basis of a factor of safety of 10 to 1, which has in all cases been worked to in the overhead equipment. The overhead conductor is divided into sections at each station, specially constructed switchgear being provided in fireproof cabins for the control of the sections. By this means it is possible to isolate any section of the line in case of necessity, and in order to secure the safety of those whose duty it will be to make repairs or carry out inspection, a system of interlocking has been devised.

A complete system of telephone communication exists between all the switch cabins as well as the signal box adjoining to them, and by the use of simple electrical relays the signalman can, in case of emergency, cut off the energy from the overhead line on the sections which are controlled by him. The switchgear has been designed so as to be as simple as possible, and it is arranged that any stationmaster, signalman, or other authorised person can easily and safely operate the switches without danger of his coming into contact with any apparatus under high pressure.

In order to meet the conditions which have been imposed in the case of the South London line as regards voltage drop in the return circuit with a view to complying both with the provisional requirements of the Board of Trade, and the requirements of the Admiralty in respect to interference with apparatus at the Greenwich Observatory, a special system of cables was rendered necessary, and a duplicate feeding system has been provided throughout the line, everything having been so designed as to secure certainty and safety of operation. Up to the present time the cables have been laid between Battersea Park and Queen's Road Stations, and 11 of the 13 switch cabins have been erected. The switchgear in four cabins has also been completed, and the work of equipping the remainder is in active progress.

The supply of energy is to be obtained by the Brighton Company from the London Electric Supply Corporation, whose mains from their station at Deptford to the switch cabin at Queen's Road Station have already been laid and tested, and whose railway generating plant, consisting of four units of some 2,000 kw. each, has been installed and is in readiness at Deptford to supply the requisite power.

For the normal work of the line it is estimated that one of these units will supply sufficient energy, so that there is little fear of failure due to lack of generating power. In addition to the above precautions, in order to avoid all possible danger of interference with the many telephone and telegraph circuits which exist along the line, the overhead wires in the majority of cases have been removed and the circuits carried in lead-covered air-space cables, metallic returns being substituted for earth returns in all cases. Many serious difficulties have been encountered during the equipment of the line, since the section which is being dealt with includes two terminal stations, together with numerous low bridges. The tunnels at Denmark Hill have also added a difficulty owing to the nature of their construction, and to the curvature of the line in the tunnels. Practically all kinds of construction which go to form a railway are met with on this length, and, as a consequence, very many obstacles have had to be considered and overcome in designing a satisfactory equipment. The nature of the embankments has rendered special foundations necessary in many cases, and these have had to be piled to a great depth in order to ensure stability. Another difficulty in connection with the low bridges at Victoria Station which has been a serious obstacle is that the railway servants have to work upon the roofs of trains in the terminal stations, and consequently the overhead conductor had to be placed at a height of 21 ft., rendering it necessary to design a special form of current collector bow capable of working satisfactorily at high speeds through a range of between 21 ft. and 14 ft., giving a vertical movement of 7 ft., and this has been by no means an easy task. It has also been necessary in order to ensure the safety of passengers and railway servants under these low bridges to design and adopt special devices whereby it will be impossible for accidental contact to be made with the high-tension equipment.

POSTMASTER-GENERAL'S ANNUAL STATEMENT

THE House of Commons went into committee on Friday on the vote of £11,821,530 for salaries and expenses of the Post Office, including telegraphs and telephones.

The POSTMASTER-GENERAL said the total revenue last year was £22,500,000, and the expenditure £18,750,000, leaving a surplus of rather over £3,750,000. The estimates for the present year gave a surplus of about the same amount. Dealing with the telephone system, he said that the department was determined that this should be carried on upon a paying basis. On the question of charges, various proposals had been made for modifying the rates, but the matter was still under discussion. At the same time, he was very glad that the Post Office had got into more intimate touch with the Chambers of Commerce and others. Complaints had been made, he said, as to overcharging upon the measured rate system, but, as a matter of fact, this was impossible. Experience had shown that so far as the automatic check was concerned, the balance of incorrect calls was in favour of the customer. Complaints upon this point in the past had been due to the fact that people were not always aware how much their telephones were used. An amusing case occurred to him recently where a subscriber, who had made a violent expostulation, subsequently inquired into the matter and found that the housemaid had been using his telephone, without authority, to communicate with her young man.

The underground telegraph system was making steady progress, about £230,000 having been spent upon it this year. With regard to overhead telegraphs, the Telegraph Construction Bill now going through Parliament would assist him very materially in obtaining wayleaves from individuals, some of whom might be designated as blackmailers.

With regard to wireless telegraphy, the Convention of 1906 had now been ratified by Great Britain for all her Colonies, with the exception of Newfoundland and the Orange River Colony, and he thought it had also been ratified by all the Great Powers, with the exception of the United States, which was, however, in favour of the principle of the Convention, and would doubtless ratify it later on. He was pleased to say that the relations between the Post Office and the Marconi Co.,

Digitized by Google

hitherto of a somewhat unfriendly character, had now been changed, and were of the most friendly kind. He was sure the company was wise in accepting the principle of intercommunication, and it was impossible for the Government, looking at the telegraph and telephone systems from past experience, to allow any monopoly with regard to wireless telegraphy. Two experimental stations had been started by the Post Office, and commercial stations were now being worked which could be used at any moment for postal purposes without having to buy up companies or monopolies.

SYMBOLS FOR PHYSICAL QUANTITIES

Suggestions of the British Electrotechnical Commission

AT the request of the Sub-committee on Symbols of the British Electrotechnical Commission, Mr. Miles Walker has sent us a long statement as to the possibility of creating a number of new symbols to represent physical quantities. The committee are very desirous of hearing the views of writers, readers, and printers of scientific literature as to the feasibility of the scheme, and any suggestions for improvement.

The desirability of a standardised notation for the representation of physical quantities in scientific books and periodicals, which shall be the same in all langages, has often been pointed out. The subject is under the consideration of the International Electrotechnical Commission with a view to international agreement, and committees in the different countries (in England under the Chairmanship of Lord Rayleigh, O.M.) are discussing this particular subject, and are dealing at present more especially with symbols for electrical and magnetic quantities. There are, however, continues Mr. Walker, two great difficulties which arise when we try to fix upon a standard notation. The first is the difficulty of persuading a number of writers and readers who have become accustomed to a certain symbol for a certain quantity to change it in favour of an equally large number of writers and readers who have become accustomed to another symbol. For instance, in France and Germany the letter "I" commonly represents the strength of an electric current, while in England and America "C" is more commonly used. In the second place, there are not enough letters in the two or three alphabets at our disposal to give a distinct symbol to each quantity, without resorting to the combination of more than one letter to form a single symbol. There is a great objection to this combination of letters, because the use of sub-script letters and numbers is required for distinguishing between particular quantities of the same general kind. If, for instance, C represents current, C_a might conveniently represent armature current, and C_1 the current in circuit No. 1. It would therefore not be good to take C_a to represent capacity, or any other quantity other than an electric current.

There is, moreover, an objection to using letters at all to represent quantities in a universal notation, because, unless initial letters are used, there is no connection in the mind between the letter and the quantity, and the symbol is difficult to remember. We cannot always use initials, because the initial letters differ in different languages. For instance, in England "R" commonly stands for resistance, while in Germany it is more convenient to use "W" for *widerstand*. Moreover, the same initial occurs for a great number of different quantities. For instance, "R" might stand for Resistance, Reluctance, Reactance, Radius, &c. One way of avoiding the above difficulties would be to create a number of new symbols which could be printed by means of type like ordinary letters, and which would represent each physical quantity in a distinctive manner. The question, however, arises as to whether a number of entirely new symbols would be acceptable to writers, readers, and printers alike, and the Sub-committee on Symbols appointed by the British section of the Commission has requested the writer to place his views publicly before the profession, with a view of obtaining suggestions and criticisms as to the feasibility of such a scheme from as wide a circle as possible.

In choosing a symbol, we would try to make a very simple picture of something that reminds us of the quantity in question. For instance, ⌇ might represent temperature. If we were told that this simple outline of a thermometer represents temperature, we would have no difficulty in remembering it. Similarly ⌇ might represent force, and the various "forces" might be derived from it; for instance, ϟ electromotive force (conventional representation of lightning), and Ω magneto-motive force.

It is not my purpose here to say what would actually be the best form of symbol for each quantity, but it is not a difficult matter to devise very simple characters which can be written quickly, easily, and with sufficient accuracy, and which can at the same time assist the memory to connect them with the quantity for which they stand. What would the printers say to the new type? The writer has taken up this matter with a very large publishing firm, and is assured by their chief expert that 200 or 300 new type would be a small matter to a modern printer, who is already accustomed to deal with many hundreds of different founts, each of which contains from 30 to 120 different symbols. He estimates that a printer in a large way of business has at his command as many as 60,000 distinct type, differing from each other either in letter, size, body, or face. The addition of 200 or 300 more would be a drop in the ocean. The size of the new type could be standardised for most purposes, and it would only be in some special case that another size would be called for. The setting-up of the formulæ with the standard size of type would be simpler than with the present system, in which sub-script letters are often unnecessarily introduced. One symbol under the present system sometimes consists of four or five letters.

If it be admitted that the introduction of new symbols is advisable, the question arises, what shall the new symbols represent exactly? Shall the sign ⌇ (temp.) represent temperature in any units, or shall it represent the number of degrees of tempeature, measured by some scale agreed upon, and embodied in the definition of the symbol. If the system of units employed be not prescribed, fewer symbols would be required, and the general writer who now says vaguely "Let T equal the temperature" would find the symbol sufficient for his purpose. But from the reader's point of view there is much to say in favour of a symbol which will embody in its definition a standard system of units. Any formula expressed in such symbols would be completely self-contained, and would be an exact statement of a physical fact. Until the units employed in any formula are known, the formula expresses only half its meaning. Perhaps some slight addition to the symbol, or even to the whole formula, might be used to indicate that the standard system of units is employed. Without that addition, the symbol would have a general meaning. For instance, ⌇ might equal temperature, while ⌇ might indicate the degrees centigrade above the absolute zero. The name of the type might be the name of the physical unit which it represents; for instance, for ϟ we might read "volts." If writers, printers, and readers, who have any definite views as to the best method of devising a system of symbols, would communicate with the technical press, they might assist in solving the many difficulties which arise in connection with this matter.

THE RECONSTRUCTION OF A COMBINED STEAM AND WATER POWER SCHEME

WE have received a copy of Mr. C. M. Shaw's reply to the discussion on his Paper on "The Reconstruction of an Electric Lighting Scheme, with Observations on the Working of a Combined Steam and Water Power Plant," read before the Nottingham Convention of the Incorporated Municipal Electrical Association. The paper, in which Mr. Shaw described how the Worcester electrical undertaking had been reconstructed with a view to obtaining fuller benefit from the water power available, and the discussion, were reported at some length in our issue of July 9th.

In his reply Mr. Shaw expresses agreement with Mr. Hoadley in his remarks regarding the multiplicity of systems, plant, &c., in use at Worcester. The rearrangement of the works under these conditions proved to be a most interesting problem, which fortunately, for financial reasons, has very seldom to be solved. The old original high periodicity single-phase system had not been changed over to polyphase, though steps were being taken to provide for such a contingency if a power load arose outside the district now served by the D.C. system. Regarding the original design of the station only necessitating the running of steam plant, on one or two occasions when the water plant was useless through drought or flood, this had caused much discussion and interest in the past, and was still a point of contention to the general public, who looked upon water power from as optimistic a point of view as had been expressed in Nottingham.

The experience of Mr. Brydges at Eastbourne was by no means an isolated case. Wholesale scrapping of uneconomical out-of-date plant was often the best remedy, though severe, to bring about economies and turn a losing concern into a profitable one. Unfortunately many engineers are deterred from taking this course through local or other reasons.

The cost of maintaining two steam stations with out-of-date plant at one works was undoubtedly the main reason for the unsatisfactory state of affairs at Worcester, and the author agreed with Mr. Vignoles as to concentrating the whole of the steam plant at one station with large steam units. With the knowledge acquired at Worcester he was of the opinion that a subsidiary station of just sufficient dimensions to contain the water turbines would have been fully justified. The cost of production at the latter station was particularly low, and the output and load factor were sufficient to give a substantial return on the outlay that would have been necessary for such a station. With regard to the governing of turbines the load on this plant was particularly constant, owing to same being used either solely for lighting or a steady power load. At times, however, trouble is experienced when two motors of 60 h.p. belonging to the Waterworks Department fall off without notice; at such times the speeds of the turbines increase rapidly, so much so that the action of governors and gate-control gear is incapable of satisfactorily controlling the speed, hence hand control is the most satisfactory in this special instance.

THE TESTING AND STANDARDISING DEPARTMENT

MR. H. A. RATCLIFF has also sent us a copy of his reply to the discussion on his Paper on the above subject read at Nottingham. He writes:—I quite agree with Mr. Wilkinson when he refers to the lack of suitable testing apparatus, as I happen to know that in many stations it is a common practice to use an ammeter having a range, say, from 0–150 amperes, for the purpose of testing ampere hour meters on a load as low as 1 or 2 amperes. The co-operative scheme was not intended to apply to all the testing work of a generating station, but only such work as necessitated the use of special and costly apparatus, and which would be outside the limits of the £250, or perhaps even the £500 collection of apparatus advocated by Mr. Wilkinson. The repair and construction work, &c., has been criticised, but I may say that in Manchester we have saved many hundreds of pounds by the repair, conversion, or reconstruction of old and obsolete apparatus; and as regards the armature winding, we have nearly 1,200 motors belonging to the hiring department, and there are usually one or two armatures or other vital parts in for repairs; the result of undertaking this work ourselves has been to save a considerable amount of delay, and reduce the cost at least 50 per cent. Several speakers have referred to the Phase Shifter. One or two Continental firms make a small phase shifter at a large price. My experience with them, however, has not been very satisfactory, and I happen to know, in the case of one firm of manufacturers, that they prefer not to use it in their own test rooms. As far as I am aware, most of the English meter makers either use choking coils, &c., or else an alternator with special phase tappings. The apparatus described by Mr. Cridge is evidently an induction motor with an open-circuited rotor; the only objections to its use are the rather considerable magnetic leakage, and the necessity for distinct stator and rotor windings. The apparatus described in the Paper has only one winding, and, therefore, is more in the nature of an auto-transformer, with the additional advantage of also being a voltage regulator. Mr. Hornby's 25s. to 30s. phase shifter is a distinct novelty, as the Continental made articles usually cost as many pounds. As far as I am aware, there is no very reliable single-phase power factor meter on the market as, owing to the theory of their construction, they are all affected, more or less, by changes in frequency. In Manchester we use an idle current ammeter as an indication of whether the current is lagging or leading, and obtain the actual power factor from the ratio of watts to volt-amperes. Mr. Haydn Harrison raises several points with which I cannot quite agree, the first being the use of a portable photometer with a screen at 45° to the horizontal. The advantages of this I am unable to appreciate, except in so far as the fact that the errors introduced by the application of the cosine law are probably less than in the case of using a horizontal screen. The method advocated of using the Simmance-Abady Photometer is not, in my opinion, a legitimate one. The cosine law is preferably introduced into the calculations, and not into the construction of a photometer. When the screen or flicker disc bisects the angle between the light under test and the standard light, the cosine effect cancels out so far as the photometer is concerned. Mr. Harrison's experience with the "Harcourt" lamps appears to have been unfortunate. I have found that most consistent results may be obtained, provided that attention is paid to a few essential details; it is most important that the necessary correction for atmospheric conditions should be applied, as otherwise errors of the order of 5 per cent. are quite possible. The great advantages of the "Harcourt" lamps are that: it is a fairly concentrated source of light as compared with the long filament of a standard incandescent lamp, and it is a *mechanically reproducible standard*. The photometer referred to by Mr. Cridge is, I believe, made by Messrs. Simmance & Abady, and appears to be a modification of, or improvement on, the well-known "Ritchie" wedge; it is only suitable for lights of the same colour, and is not intended to supersede the flicker photometer. Mr. Burnett refers to the question of stop-watches. Watch errors are very slight if the right sort are used. Ordinary fly-back chronographs are of no use for meter testing. The best type of watches are those having a stopping and starting detent on the balance wheel, and a slow zero return motion. Watches constructed on this principle have no starting error, and the timing error is insignificant, as even such a large variation as five minutes a day would only be a matter of 0·35 per cent. Other matters referred to by Mr. Burnett are rather outside the scope of the Paper, as details of tests have not been included, but I agree with him that dial tests are very important, and in Manchester no meter is passed unless it has registered at least 10 units on the dials; usually about 20 to 30. Makers' constants are never taken as correct without checking, and in the case of complex and three-phase meters, &c., the actual constant is always calculated from the gearing. Incidentally, experience has shown that the makers' certificates referred to by Mr. Wilkinson have never yet been found to agree with the actual results of the tests on the meters. Twenty seconds is too short a time for a reliable revolution test, and at least 45 seconds should be taken as a minimum figure.

Territorial Army.—The following appointments have been announced in the *London Gazette*:—*Southern Wireless Telegraph Company, Royal Engineers:* Harry Bryant Matthews to be Captain. Dated April 1st, 1908 *Southern Cable Telegraph Company, Royal Engineers:* Robert Bucknall Bowker to be Lieutenant. Dated April 1st, 1908. *Southern Air Line Telegraph Company, Royal Engineers:* John William Danielsen to be Captain. Dated April 1st, 1908; Arthur James Dickinson to be Lieutenant. Dated April 1st, 1908. *Western Command Telegraph Companies, Royal Engineers (Army Troops):* Captain Roland Martin Macrory, Royal Engineers, from the Adjutancy of the 1st Lancashire Royal Engineers (Volunteers), to be Adjutant for the residue unexpired of his tenure. Dated April 1st, 1908.

The *Times* states that the allocation of London Territorial Engineer units includes London Wireless Telegraph, London Cable Telegraph, London Air Line Telegraph, and London Balloon Companies, R.E., all of which have been formed from the London Division of Electrical Engineers. The designation of the unit detailed for the "Defended Ports" is "London Division Electrical Engineers." (Temporarily retained.)

REPORT OF THE ELECTRICAL INSPECTOR OF FACTORIES AND WORKSHOPS

THE annual report of Mr. G. Scott Ram, H.M. Electrical Inspector of Factories, contains the following table of accidents in electricity supply works reported during the year 1907 :—

Table I.

Accidents at Electrical Generating Stations and Sub-stations, 1907.

Description.	Electricity Supply Companies and Local Authorities.		Private Stations.	
	Non-fatal	Fatal.	Non-fatal.	Fatal.
Non-Electrical—				
At engines, pumps, and generators..	29	—	5	—
At boilers and steam plant	61	2	10	—
At coal handling plant	17	—	2	—
Falls	53	4	3	1
Struck by falling bodies	29	—	3	—
Miscellaneous	57	1	5	—
	246	7	28	1
Electrical—				
At switchboards, when engaged in ordinary routine work; mostly due to faulty design of apparatus..	10	—	1	—
Cleaning, repairing, &c., at "live" switchboards	13	1	3	—
Cleaning, repairing, or other handling of switchboards supposed to have been made "dead"—				
(*a*) Skilled persons	1	—	--	—
(*b*) Unskilled persons	—	—	—	—
Adjusting brushes	9	—	2	—
Miscellaneous	15	1*	2	1
	48	2	8	1

* Suicide.

The electrical accidents, although showing a slight increase, are again not many. Under the first heading, three were due to mistakes on the part of the switchman. One was due to the failure of a large oil-type fuse, whereby the oil was ignited and severely burnt the arms and face of the attendant.

Under the second heading, the fatal accident occurred in an extra-high pressure sub-station (11,000 volts) to a boy, who had been told to grease two switches which had been made "dead." Having done this work, it is supposed that he turned his attention to the next switch, which was "live," with the result that he was killed. This accident points to the danger of not screening off the live sections from the dead portion of a switchboard when work has to be done, and again draws attention to the undesirability of employing unskilled persons, particularly boys, in such places unless under the immediate and constant supervision of a competent person. Several others of these accidents occurred at high-pressure and extra high-pressure switchboards, and again emphasise the danger of switchboards not being arranged so that they can be made "dead" in sections when work upon them becomes necessary. In one case the chief engineer of the station had undertaken the work of overhauling a high-pressure switch himself, and met with an accident, receiving severe injuries.

The number of accidents reported in Table II. of factories, engineering works, &c., again shows an increase over the previous year, and is double the number of two years ago. The increase is probably due to the extended use of electrical energy in factories, and possibly more attention has been paid by occupiers to the necessity of reporting accidents under the Notice of Accidents Act, 1906. There is little, if anything, new in the circumstances of the accidents.

One of the fatal cases was due to the absence of any protection on a three-phase medium pressure motor starting switch. The switch was in a works and not in a motor-room or switch-room accessible only to authorised persons Owing to the nature of the industry, the floor at the switch would always be wet. There would, therefore, always be the risk of a fatal accident to anyone touching a "live" part of the switch. The installation was put in, and the power supplied by an authorised undertaking, subject to Board of Trade regulations. Under these regulations the switch should have been so enclosed and protected as to prevent danger of shock in the ordinary handling. This regulation had, however, been entirely ignored. The victim of the accident certainly had no business to touch the switch, and was not authorised to do so, but it should have been impossible for anyone to have touched any live part.

Table II.

Reported Electrical Accidents in Factories, Engineering Works, &c., other than Electrical Generating Stations and Sub-stations, 1907.

Description.	Non-fatal.	Fatal.
Arcing of switches	17	—

* Fall following shock. † Due to a practical joke.

Another fatality shows the necessity for properly protecting insulated wires in engineering works where they are liable to damage. The insulation of a conductor was cut through by the edge of a piece of iron which a man was carrying. Although the pressure was only 250 volts, alternating-current, the man was killed. Another fatality was due to a man touching with an iron rod the frame of an arc lamp working at high pressure, the frame of the lamp forming part of the circuit. Another accident again exemplifies the danger of alternating current at low pressures. It occurred in an engineering works. A man was engaged at a saw bench where hot metal was being cut up by a circular saw. The saw was driven directly by a three-phase motor working at 350 volts per phase and, therefore, probably only 200 volts above earth. After cutting a piece of metal the man, while still holding it with tongs on the saw bench, told his assistant to switch off the current. Immediately the switch was pulled off the man at the saw received a shock and was killed. The saw bench had become electrically charged through a trifling breakage at the switch. A spring of the switch broke and made contact with the metal cover. This cover was connected by a wire to the lead-covering of the cable leading to the motor, and which rested on the motor-frame. Another wire connected the lead-covering of the cable to a bolt passing through a piece of wood in such a way that when screwed up the end of the bolt was forced against a metal column of the building, which it was supposed would form an efficient earth connection. The earth connection proved useless, probably because the bolt had not penetrated the coating of paint on the column. It is, however, a question whether earthing to a column of a steel-frame building is in any case sufficient. There were a large number of similar columns supporting the roof of the shop, all more or less in electrical connection with each other, and it might reasonably be thought that such an "earth" would be adequate. The columns, however, do not go far into the ground, which may be dry, and they rest on concrete blocks. In the case of fall following a shock, the victim, a labourer, was sent to adjust a trolley contact at a great height from the ground, the pressure not having been previously switched off. In the test-room fatality, no satisfactory explanation could be offered as to why the deceased person, an apprentice, should have got into the position in which he was found, grasping live terminals, 440 volts, alternating current. The case of the practical joke again emphasises the danger of alternating current of low voltage, 200 volts. A wire was connected from a wall plug to a door handle. The victim took hold of the handle and received a fatal shock. No doubt the perpetrators of the "joke"

Digitized by Google

had no idea that the ordinary lighting supply voltage could be dangerous. The medical evidence in this case showed that the deceased person was not in good health, but other cases of fatal shock at low pressures with alternating current show that the danger exists even when the person may be quite sound. Another fatality was due to a faulty hand-lamp. The metal-work of the lamp, including the wire-guard to the lamp, became live. The man was in connection with earth, and received a shock. He could not let go the lamp, and was killed. The pressure was 250 volts alternating current.

Mr. Ram continues :—The danger in the use of hand-lamps as ordinarily constructed is seldom realised, and can so easily be guarded against that I propose to refer to the matter at greater length. The danger arises from the construction of the lamp being such that any metal-work used is very liable to become electrically charged. If, therefore, a person holding such a lamp happens to be standing on metal-floor plates, or on damp ground, or is otherwise in connection with earth, he may get a shock, and in all probability he will be unable to release his hold of the lamp, and a fatal result will ensue. The accompanying photograph, Fig. 3, shows three hand-lamps, each of a different pattern, and each of which has been the cause of the death of a man under the circumstances indicated above. In each case the current was alternating and low pressure. Each lamp has an insulating handle, but this has not prevented a fatal accident. The lamps A and C have each a brass tube passing through the handle. The end of the brass tube is screwed into the lamp holder, and the other end into a ferrule, which serves to hold the insulating handle in position and provides an attachment for the metal hook, by means of which the lamp may be hung up. In each of these lamps, if there occurs any defect by which any part of the metal-work should make contact with the conductors, the whole of the metal-work will become live. Although a person may be grasping the wood handle in the proper way, he is liable to touch the brass ferrule at one end or the gallery of the protecting cage at the other. If he is at the same time standing on "earth," he will get a shock which may prevent him dropping the lamp; in fact, he will probably grasp it all the tighter, although the actual point of contact between his hand and the charged metal at one end or other of the handle may be very small. Lamp B is similar, but has no brass tube passing through the handle. The handle, however, is not large, and a man holding it is liable to have his thumb upon the brass socket into which the handle fits. This socket terminates in a short brass tube, which screws into the lamp-holder, and is consequently in metallic connection with the lamp-holder, the gallery, and cage. Should these parts become live through any defect, the person holding the lamp may again be unable to release his hold. In the case of each of these lamps, the metal-work became live when the persons holding them were in connection with earth, and were consequently unable to let go and were killed. Examination of the lamps shows the following defects by reason of which the metal parts became "live." In lamp A the flexible wires pass from the lamp-holder through the brass tube inside the handle and out at a hole in the side of the brass ferrule. The edge of this hole is bushed with insulating material, but the edge of the end of the brass tube inside the ferrule is not so bushed and has a sharp edge. The insulating covering to the flexible wires appears to have been cut through at this point, thus causing the whole of the metal-work to become "live," and hence the accident. In the case of lamp C, the flexible wires pass out through the end of the brass ferrule, and this, of course, is again a weak spot, the covering of the wires being liable to be injured at this point. This, however, does not appear to have been the cause of the metal-work becoming "live" in this case. There is another defect which I have indicated in Fig. 1. The lamp-holder is screwed on to the end of the brass tube, which passes through the handle, the flexible wires passing through this brass tube to the terminals fixed in the porcelain block in the holder. The fit of the threads in the holder and the brass tube is very easy, and the holder cannot be firmly fixed unless it is screwed on the brass tube, or rather the brass tube is screwed into the holder as far as it will go. This, until the flexible wires are in position, means that the brass tube is screwed in so far that it becomes jammed against the porcelain block. The holes in the porcelain block, into which the ends of the flexible wires are threaded, are somewhat wider apart than the diameter of the brass tube. Consequently, when the flexible wires are put in place, the brass tube is screwed hard up against them, nipping them between its sharp edge and the porcelain block. As there is no grip upon the flexible wires elsewhere within the handle, and as the lamp may be frequently carried about by means of the wires, the whole weight will be taken by the latter at the point where they are nipped. Under such conditions it is practically a foregone conclusion that the insulation, even if it should escape damage in the first instance, will be cut through after the lamp has been in use for a short time. In the case of lamp B the same defect occurs, although it appears that it may have been considered in the original design, the brass tube being only a short one fitted into the end of the brass socket, into which the handle fits, this socket forming a shoulder against which the lamp-holder can be tightly screwed. The brass tube, however, is just too long, and before the holder can actually be screwed hard up against the shoulder the end of the brass tube is already cutting into the wires against the porcelain in the lamp-holder. These may appear very trifling defects, but it is nevertheless upon such that the life of the man using the lamp may depend. There is no difficulty whatever in constructing a lamp which should be free from these defects, and under ordinary circumstances absolutely safe.

The two most important points to be borne in mind in the design of a lamp for use in dangerous places, *i.e.*, where the user is in connection with earth, are (1) that there shall be no metallic connection between the lamp-holder and any other metal part of the fitting, and (2) that the flexible wires in passing from the lamp-holder shall not be taken through a metal tube or be otherwise touching any metal part of the fitting. Fig. 2 shows a very simple and inexpensive type of lamp, of which a number are in use, and which is very much safer than any of those shown in Fig. 3. The body is made from a piece of oak, about 3½ in. in diameter at one end and turned down to form a handle. The flexible wires pass through a hole down the centre to the lamp-holder, and are clamped near the end of the handle, so that no strain can be put upon the connection in the lamp-holder, which is of the "batten" type, and is screwed to the flat disc end. The wire cage is attached by screws to the outside of the disc. There is no metallic connection between the lamp-holder and the wire cage, and there is no other metal used in the construction of the fitting, except the hook at the end of the handle used for the purpose of hanging up the lamp. This hook should, however, be replaced by a leather or other non-metallic loop, as with constant use it might injure the insulating covering of the flexible wires where it rubs against them just beyond the end of the handle. With this slight alteration this lamp would be entirely free from the defects described in reference to those shown in Fig. 3, and would probably be cheaper. As a result of my remarks on this subject in my last report, the lamp shown in Fig. 4 has been brought out. In this case again the body of the lamp is of wood. The lamp-holder, which is of the "cord-grip" type, is fixed in a vulcanite ring or cylinder, which is extended so as to form a guard or sheath completely surrounding it. The wire cage is attached to a metal ring, which is screwed to the outside of the wood base. There is no possibility of any metallic contact between the cage and the lamp-holder. The lamp-holder is supported in such a way as to give a large insulating surface between it and the metal cage-ring in view of preventing leakage by a film of moisture if the lamp is used in a damp situation. The only weak spot appears to be in the metal hook, which, however, can, without any difficulty, be replaced by a leather or other non-conducting loop.

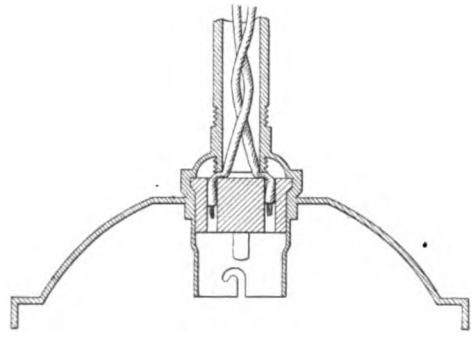

FIG. 1.—DEFECTIVE ATTACHMENT OF LAMP-HOLDER, SHOWING FLEXIBLE WIRES NIPPED BETWEEN PORCELAIN AND END OF BRASS TUBE.

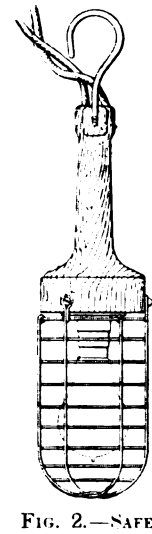

FIG. 2.—SAFER PATTERN OF LAMP.

In the course of inspections during the year further examples of dangerous conditions of electrical plant, such as have been described in previous reports, were met with. These are enumerated as follows :—

Switches designed so that the hand may touch live metal when grasping the handle; switches and fuses fixed to the same base in such a way that in switching on the operator's knuckles will touch the bare fuse metal; oil cups, requiring frequent filling up, placed close to high-pressure brush-gear on generators; on main switchboard of authorised undertaking, main fuses fixed at back of board behind bus-bars; extra-high pressure rubber-covered cables, not otherwise protected, fixed in generating station basement amongst steam and exhaust pipes, and in the way of making joints in the same; switches for alternating current, medium pressure, in factories, without any protection, in some places over wet floors; earth wires of motors, &c., connected to gas pipes; motor switches in factories fixed behind

Digitized by Google

running belts; iron foot-plates behind switchboards having bare conductors; extra-high pressure coils of generators and motors unguarded; medium-pressure switchboards placed one behind the other with bare metal on both sides of the narrow working space; high-pressure alternators with no protection at high-pressure collectors and terminals where likely to be accidentally touched; high-pressure and medium-pressure switchboards with insecure floor at back; extra-high pressure isolating switches, worked by attendant from a ladder in a dangerous position instead of by a pole from the floor level; extra-high pressure

Electricity from Peat in Germany.—The Siemens Schuckertwerke and the Siemens Elektrische Betriebe Akt.-Ges. have been granted a concession for 75 years by the Prussian Government for the generation and distribution of electrical energy in the East Friesland peat district. A power station consuming peat only will be built near Aurich, and energy will be distributed in the surrounding district, and also to the towns of Emden, Leer, and Wilhelmshaven. The above company will lay cables up to the outskirts of the towns, but the distribution network in the towns will be laid by the town corporations.

THE PARIS TELEPHONE SYSTEM

WE published in our issue of June 25th an account of the position with regard to telephone matters in Paris, which showed that the benefits from the reconstruction of the exchange system, recently put in hand, are not yet apparent. One of the difficulties seems to be that in Paris the subscriber himself provides his instrument, and that, in consequence, a variety of patterns are in use, several of which are quite unsuitable for use with the central battery working that is being inaugurated. An amusing incident was recorded in a daily contemporary a short time ago. The *Figaro* advised all its readers who had trouble with their calls to ring up M. Simyan, the Under-Secretary for Posts and Telegraphs, at his private house. The first complaint call was at seven o'clock in the morning, and was answered by M. Simyan himself, and it is stated that between that hour and eleven o'clock on the following night 1,300 calls for his number were registered. M. Simyan's number was then changed.

The *New York Times* has suggested that part of the troubles is due to the similarity of the French numerals when heard through the telephone: thus "six" and "dix," "vingt" and "cinq." The possibility of error in this connection, our contemporary suggests, is increased by the fact that the exchanges or districts bear numbers instead of names. Thus M. Simyan's number was 525,59, and telephone men will certainly realise the difficulty of successfully transmitting the sibilants in cinq cent, vingt cinq, cinquante neuf through an inefficient microphone; possibly the 1,300 calls in two days would have been largely increased if the number had been an easier one.

A Parisian technical contemporary gives a few notes on the technical work of the reconstruction of the Sablons exchange, which replaces the Passy exchange, and also takes part of the lines for the Avenue de Wagram exchange. Some structural alterations in the building were necessary chiefly on account, it appears, of the extra weight of the new central battery equipment, and the usual difficulty with subscribers having extension instruments was probably heightened by the fact already alluded to that the subscribers have put in their own instruments. It is stated that the central battery has an E.M.F. of 12 volts only, but this, we think, must be an error or a misprint. The battery is charged through a motor generator connected to the supply company's mains, and a petrol motor set is used as a standby.

Five new exchanges will be required, as well as one now under construction, and three hundred new junction lines are to be provided. There is considerable agitation also for additional trunk lines, especially between the larger towns. The tariff is also a hot question for dispute; it is stated that after deciding upon a reduction, the Administration withdrew the proposal owing to the impossibility under present conditions of connecting up the large number of new subscribers that it would attract.

Local Authorities' Accounts.—The Finance Committee of the London County Council has had under consideration, in so far as it relates to the London County Council, the report of the Departmental Committee, appointed by the President of the Local Government Board in January, 1906, to inquire and report with regard to the accounts of local authorities. This committee dealt with (1) the systems on which the accounts of local authorities are at present kept; (2) the system on which the accounts of local authorities should be kept; (3) the regulations which should be made in regard to the accounts of local authorities. In a long report they discuss as to how far the present method of keeping the Council's accounts falls in with the recommendations of the Local Government Board Committee, and make the following recommendations :—(1) That all the rate fund accounts and estimates should be placed on the income and expenditure basis instead of the present receipts and payments basis. (2) That arrangements should be made for notifying the comptroller promptly of all orders issued by spending departments for goods to be supplied or work done, and of moneys due to be received. (3) That a monthly return of expenditure and liabilities incurred under each annual vote should be furnished by the comptroller to each committee. (4) That the General Purposes Committee should be requested to revise the regulations as to stores. (5) That the Money Bill tables and schedules, and other similar statements, should be prepared on the same basis as is proposed to be adopted for the rate fund accounts and estimates. With regard to the additional work which the alterations will involve, it is estimated that thirteen additional assistants will probably be required in the Comptroller's Department at an estimated cost for the first year of £840, and in the fourth year £1,125, apart from the cost of office accommodation. The committee, however, are strongly of opinion that the Council will be fully justified in incurring the additional expenditure proposed, and that the advantages accruing from the stricter accounting methods will more than compensate for the additional cost of the new scheme.

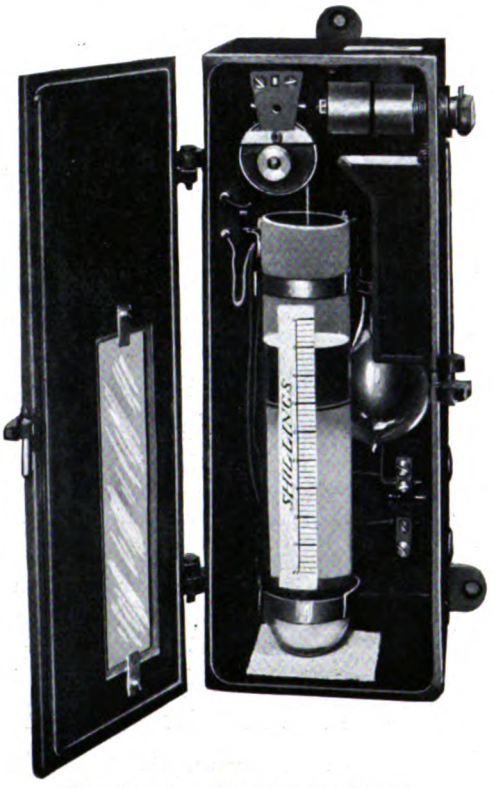
A NEW ELECTROLYTIC PREPAYMENT METER

IN small installations, and particularly in such cases where free wiring by the supply authorities is undertaken, the disproportionate cost of the meter is a very serious matter. For many small installations also a prepayment meter is to be preferred to the ordinary recording meter, and there is a considerable field for a cheap and satisfactory prepayment meter. An electrolytic prepayment meter has been brought out by the Electrical Apparatus Co., Ltd., of Caxton House, Westminster, which, besides having some features of interest, is worthy of consideration owing to its low cost. This meter, which is illustrated below, depends for its operation on the electrolysis of water. Briefly, the action is as follows :—A voltameter filled with a caustic soda solution has one electrode permanently fixed to the side and the other suspended in the centre, and is directly in series with the consumer's lamps. The passage of the current electrolyses the solution, and lowers its level in proportion to the amount of current flowing. When the level of the solution falls



ELECTROLYTIC PREPAYMENT METER.

below the suspended electrode, the circuit is broken and the supply of electricity stopped until the suspended electrode is lowered and again immersed in the solution. The above is the principle of the meter, but a few modifications were necessary to render such a meter fit for practical use. By the introduction of a third fixed electrode into the voltameter, the circuit is not broken when the level drops below the suspended electrode, but a lamp inside the meter is put in series with the consumer's lamps, thus indicating when it is necessary to lower the electrode. It will be noticed that the meter consists of three component parts : the voltameter, the drum suspension for the electrode and the coin-freeing mechanism, and the lamp used as a dimming resistance.

The containing vessel of the voltameter is a plain glass cylinder. The fixed electrodes are not fused into the glass, but consist of two nickel strips bent over the edge at the top, which run to the bottom of the container, where they are kept in place by an insulating separator, to which they are rivetted. Suspended in the voltameter by a nickel wire, which also leads in the current, is a bell which carries the main electrode. This bell has a hole through the centre, and contains the main electrode at which the break takes place. This is of great importance, as the gas which is given off at the electrode rises up into the bell, and escapes through the top. The other gas does not rise into the bell, but escapes round the edge. The nickel wire which holds the bell and leads in the current passes round a drum which is connected by a simple worm gear to one half of a slotted cylinder. The other half of the cylinder is attached to the outside handle. The insertion of a shilling connects the two halves of the cylinder, and allows the outside handle to be rotated through 180°, when the shilling drops. The rotation of the drum lowers the bell by a definite amount, in accordance with the stated rate of charging, and also displaces solution. Several shillings can be inserted at one time. Evaporation from the surface is prevented by a thin layer of high flash paraffin oil. The meter is constructed to take about 45s. before requiring to be refilled. The refilling is a very simple matter, and is effected by winding up the bell by means of a milled nut and filling the tube with plain water. The diameter of the tube can be varied to suit the rate of charging in force, the diameter being so chosen that a drop of one-eighth of an inch, produced by a half turn of the drum, corresponds to one shilling's worth of electrical energy. The insertion of two shillings, that is, a complete turn of the drum, will immerse the electrode so far that two shillings' worth of energy can be obtained before the dimming lamp is put in circuit. Energy consumed while the lamps are dimmed is paid for by the next shilling inserted, as the level is falling all the time current is passing, the electrolysis taking place between the two fixed electrodes.

ARC-LAMP STANDARDS FOR THE CITY

THE accompanying illustration is that of a model arc-lamp standard especially designed for use in the City of London. The height of the standard from the base to the centre of the lamp-globe in the full size standard would be 28 ft. The present design includes no provision for lowering the lamp, but sufficient space between the lamp and the base of the bracket for lowering the globe is allowed. The cleaning and adjustment would thus necessitate the use of a tower, as is already the practice in Oxford Street (Marylebone) and in Cannon Street. Some few feet from the base will be noticed the switch and fuse-box, the four sides of which are decorated with the City arms. The design, which is registered, is the property of Messrs. Thomas Elsley, Ltd., of 28 Great Titchfield Street, W., and was submitted to the electrical engineer to the City, Mr. A. A. Voysey, as a possible design for the lamp standards in the City. There is considerable field for a really artistic standard for use in the streets of the City of London, although there are a number of cases where the streets are narrow in which preference may be given eventually to the cross-wire suspension system as is used in Cannon Street, or to some form of wall bracket. We are indebted to Mr. A. A. Voysey for permission to photograph the model.

DESIGN FOR ARC-LAMP STANDARD FOR THE CITY OF LONDON.

Breakdown in a Water Power Station.—A remarkable mishap, by which the plant in the Cazadero station of the Portland Railway, Light & Power Co. was almost completely wrecked, is described in the *Electrical World* (New York). It appears that the governor on one of the water wheels stuck in some way, allowing a full head of water to rush through the turbine driving the generator, which straightway proceeded to speed up. When the attendant endeavoured to shut the emergency gate, this was found to be jammed and inoperative. The generator was soon revolving at a terrific pace, which dislodged some of the pole pieces and threw the revolving-field structure out of balance, so that the entire generator burst asunder in a very short time. The governor of the adjacent machine was struck by a piece of flying metal and rendered useless. As a consequence the gate flew wide open and the generator "ran away," meeting the fate of the first machine. Pieces of this second generator were hurled through the building and the remaining generator suffered destruction also. The complete demolition of the electrical gererating apparatus was brought about in three minutes. The water wheels, from all reports, were undamaged save for the breaking of the shafts, and shortly after the accident were stopped from the head gates. One end of the station contained a temporary wooden floor and wooden roof for convenience in installing additional machinery. This end of the station was set on fire by the wreckage which flew in that direction. The switchboard end of the station was undamaged. All of the 18-in. shafts were broken off and twisted. There was no interruption to the service resulting from the destruction of the station, for at the time of the accident, about 6 o'clock in the morning, very few lamps were in use and few cars were running. The apparatus of an auxiliary steam station was immediately brought into service, and is now running overloaded to take care of the load.

THE ELECTRICAL EQUIPMENT OF THE STANNINGLEY IRONWORKS

AMONGST the many industries which have effected considerable economies in their working by the adoption of electric driving under conditions of a public supply the trade or business of "engineers," with its

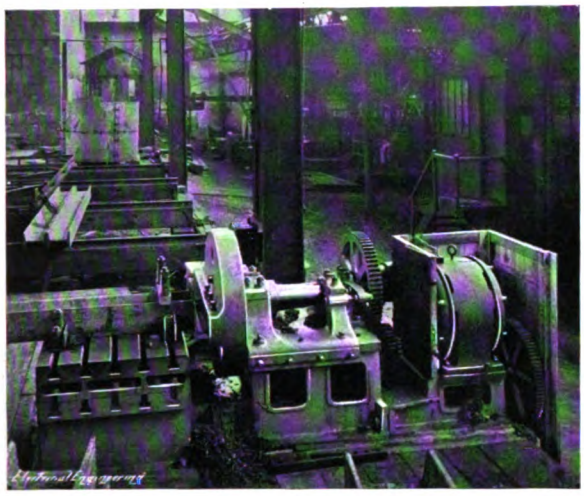

FIG. 1.—ELECTRICALLY-DRIVEN MILLING MACHINE FOR GIRDER ENDING.

many branches, is one of the most prominent. The demand for power is of so intermittent a character that the cost of a ready-to-serve supply of steam is proportionately very much higher than in the case of

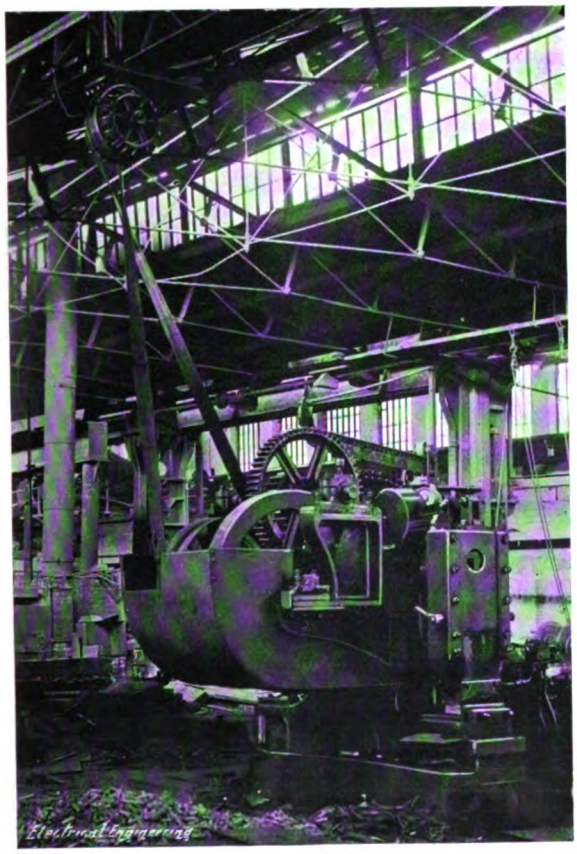

FIG. 2.—PUNCHING MACHINE DRIVEN FROM MOTOR OVERHEAD.

trades where the demand is of a much steadier character. Furthermore, the cost of a self-contained supply is, in many cases, considerably increased from the fact that the business requires a large amount of ground space for storage and easy manipulation, necessitating either a number of isolated steam plants or a large amount of heat-wasting piping.

These unavoidable increases in cost are entirely eliminated where the power is derived from a public source, and one of the latest of these conversions is to be seen in the case of Messrs. John Butler & Co., Ltd., of Stanningley Ironworks, near Leeds, who have for many years been one of the foremost engineering firms connected with bridge building and similar construction work. A group of boilers and a number of engines of varying capacity were originally used for driving the machinery in connection with the work turned out; but on the conversion of the works to electrical driving, these have been dispensed with and the boilers removed.

The works are now electrically driven from the mains of The Yorkshire Electric Power Co., whose

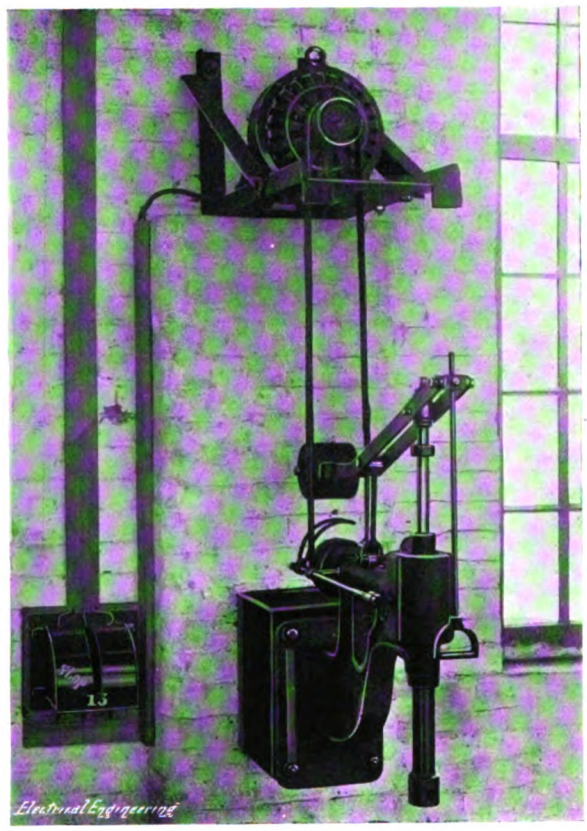

FIG. 3.—WOOD BORING MACHINE.

Thornhill power station is $14\frac{3}{4}$ miles away. The supply is given on the three-phase alternating current system, the pressure being transformed on Messrs. Butler's premises from 10,000 volts to 400 volts, 50 cycles. A duplicate supply is provided for by means of two ·05 sq. in. three-core paper insulated L.S.W.A. Callenders cables teed from the Yorkshire Electric Power Co.'s trunk mains. Each service cable terminates in a three-pole non-automatic oil switch through which the bus-bars and transformers are supplied. The transformers, meters, and switches were supplied by the British Thomson-Houston Co., Ltd., of Rugby. The transformers are 10,000/400-volt with delta connected primaries and star-connected secondaries, and are installed in two banks, each bank being controlled on the extra high tension side by one three-pole 10,000-volt automatic oil switch and on the low tension side by a 500-ampere, three-pole knife switch. Each trans-

Digitized by Google

former is capable of being readily disconnected on the extra high or low tension sides, should the variation of the load or any other reason justify the exclusion of one or more transformers. The quantity of electrical energy consumed is registered on the low tension side by three 1000-ampere, 230-volt Ferranti meters fed through current transformers, the pressure coils being connected to the earthed neutral of the power transformer.

The transformers, switches, meters, and other gear are contained in a two-floored sub-station, the upper portion being devoted to the power company's switchgear, whilst the lower portion is divided into two parts, one containing the transformers and the other Messrs. Butler's low tension switchboard, and the meters of The Yorkshire Co. The 10,000-volt switchgear on the upper floor is completely enclosed in brick cells provided with sheet-iron screens. The switches are mounted on the front wall of the cell with the operating links carried through and the handles mounted on the outside.

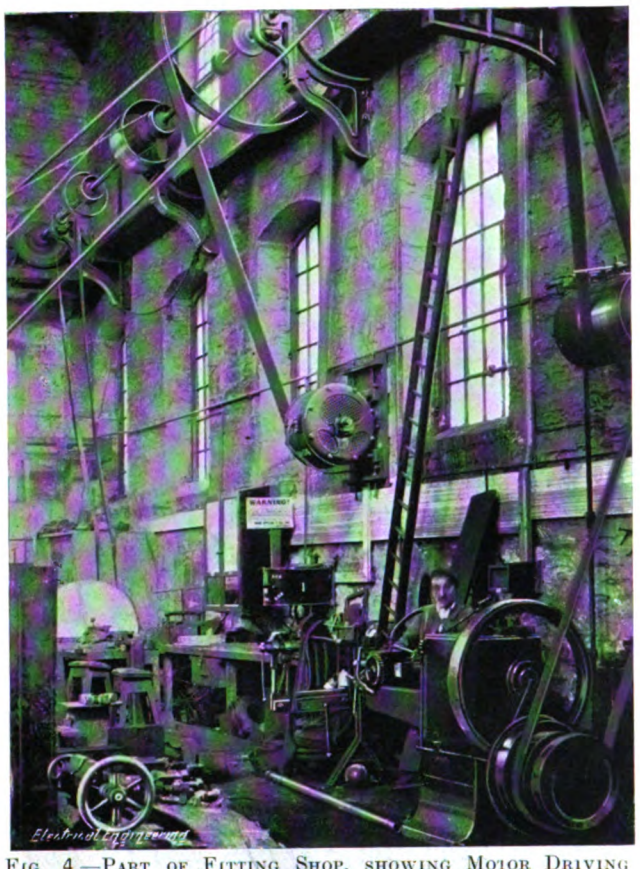

FIG. 4.—PART OF FITTING SHOP, SHOWING MOTOR DRIVING SHAFTING.

The contractors for the installation were Messrs. Wilson Hartnell & Co., Ltd., of Kirkstall Road, Leeds, one of the oldest-established firms of electrical contractors in this country. The supply is controlled by Messrs. Butler & Co., from the main distributing board in the lower floor of the sub-station already mentioned, from which emanate six separate circuits designated as A, D, E, H, K, and L respectively, the sub-distributing boards from each of these circuits being fixed in convenient positions for the control of a group of motors, each motor being on its own separate circuit, and fused from the sub-distributing board which controls it.

Circuit "A" consists of seven motors with a total horse-power of 100. Among these are the milling machines for girder ending shown in Fig. 1, the cold saws, and various drills. Circuit "D" comprises 11 motors totalling 147 h.p. Examples of these are a punching machine shown in Fig. 2, and the wood-boring machine in Fig. 3. Other machinery electrically driven from this circuit includes horizontal rolls, &c., in one of the machine shops, plate edge planers, &c., and a considerable amount of other machinery. Circuit "E" consists of seven motors of 135 h.p. driving, blowers, drills, punching and shearing machines, &c., in the girder shop, waggon shop, and new smith's shop. Circuit "H" has 18 motors, with a total capacity of 250 b.h.p., there being nearly 100 machines for various purposes and of varying sizes in this circuit. Fig. 4 shows the method of mounting the motors on the wall of the fitting shop, and the convenient position of the starter. "K" circuit has 1–10 h.p. motor driving a crane, and "L" circuit two motors of 100 and 140 b.h.p. respectively, driving an accumulator and air-compressor. A small steam-driven air-compressor now driven electrically is also on this circuit.

Altogether, in the six circuits there are 52 motors of a total capacity of 962 b.h.p., varying from 2 to 140 h.p., running at speeds of from 470 to 1,410 revs. per minute. The plant has now been at work for a period of about nine months, and is working so satisfactorily that it should be the means of inducing many others to consider seriously changing over to the electric drive.

New Telephone Charges.—The Committee appointed by the Associations of Chambers of Commerce to deal with questions relating to the new telephone charges has adopted a suggestion by the Postmaster-General, and will nominate a deputation to meet the Post Office and the National Telephone Co., with a view to obtaining figures and arguments in support of the new telephone charges.

Duty on Tramcars into Finland.—The Finnish Customs Department has decided that imported electric tramcars shall be dutiable as follows:—Ready mounted, on axles and wheels, with electric motors attached, £32 each (N.B.—The motor, which is dutiable separately, pays at the rate of 6s. per cwt.); ready mounted on axles and wheels, but without motors, £32 each; with wheels and axles, and electric motors separate, cars are dutiable as those with motor attached.

Light Railways.—The Board of Trade has confirmed (1) the Portmadoc, Beddgelert and South Snowdon Railway (Light Railway) Order, 1908, authorising the Portmadoc, Beddgelert & South Snowdon Railway Company to reconstruct, construct, and work the railways authorised by the Portmadoc, Beddgelert and South Snowdon Railway Acts, 1901 and 1904, as a light railway under the Light Railways Act, 1896, and authorising the construction of a light railway in the county of Carnarvon, from the termination of the railway authorised by the said Act of 1901 near Beddgelert, to Bettws-y-Coed, and amending and consolidating the capital and borrowing powers of the company, and for other purposes. (2) Portmadoc, Beddgelert & South Snowdon Railway (Light Railway Extension at Carnarvon) Order, 1908, authorising the construction of light railways in the borough and county of Carnarvon, being a deviation and extension of the authorised undertaking of the Portmadoc, Beddgelert & South Snowdon Railway Company, from Dinas to Carnarvon, and the abandonment of a part of the said undertaking.

"Indestructible" Cables.—We have received some particulars of a form of cable which has been developed by the "Indestructible" Cable Company, of 47–51, Park Street, S.E., in order to obviate the insulation troubles which are often encountered under severe conditions of exposure to weather or acid fumes, &c. The inventor, Mr. Hackethal (Telegraph-Director of the Imperial German Post Office), found out after careful and long experiments that a mixture of minium or red lead and linseed oil which *per se* is a good rust preventative, offers in its hardened condition a great resistance against atmospheric and chemical influences. It has been found possible to embody this material in the insulation of a variety of forms of cable and wire, and to thus produce an insulating covering of great durability. These wires are particularly recommended for fire alarm, electric clock, and other signal installations which are apt to touch or interlace one another in exposed situations, and also for telegraph and telephone lines crossing overhead power circuits, as well as for chemical works, accumulator rooms, &c., where fumes harmful to ordinary insulation abound. It is claimed that exposure to air, so far from causing the insulation to deteriorate, increases its hardness and durability as well as its insulating property. We understand that material of this description is in extensive use in the Simplon tunnel, and has been found particularly suitable for tropical climates.

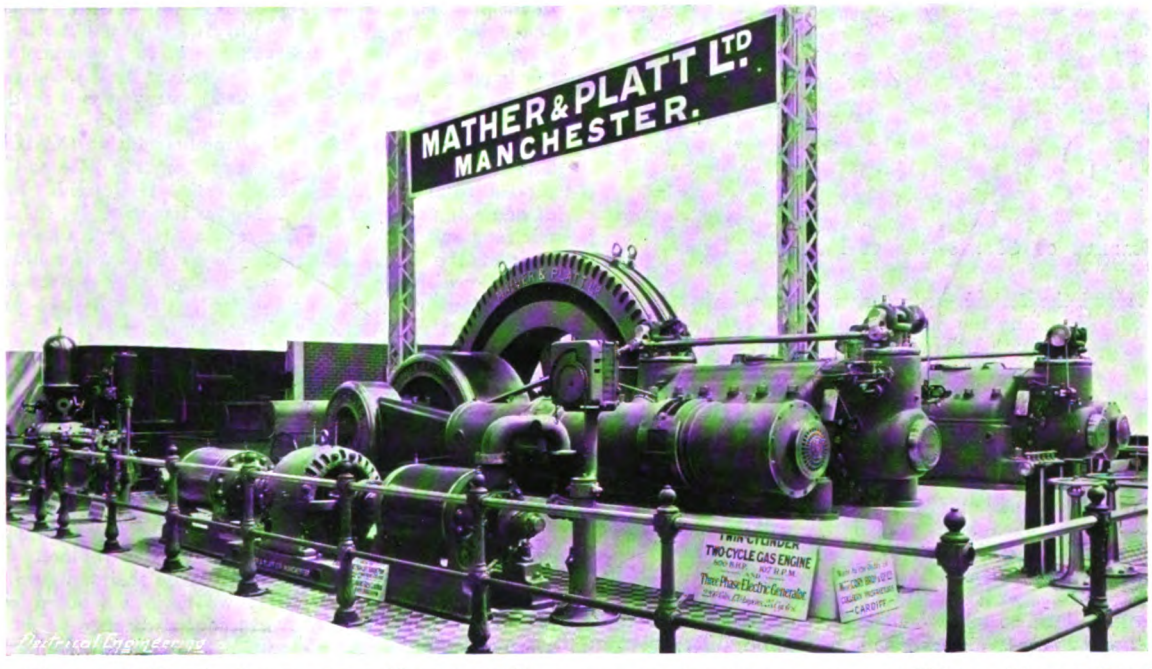
ELECTRICAL ENGINEERING AT THE FRANCO-BRITISH EXHIBITION

THE features of electrical engineering interest in the Franco-British Exhibition include not only the exhibits themselves, but also the arrangements for the supply of current throughout the exhibition, the lighting, and the various applications of electrical power. In our issue of May 7th (ELECTRICAL ENGINEERING, Vol. III., pages 687 to 690), just before the opening of the exhibition, we described pretty fully the arrangements for the distribution of current supplied by the Hammersmith Borough Council and the Notting Hill and Kensington Electric Supply Co., and the utilisation of this supply for power and lighting. We also indicated at the time the extent of some of the principal examples of generating plant that were being erected for taking part in the supply within the exhibition. A further article, published on June 18th (ELECTRICAL ENGINEERING, Vol. III., pages 930 to 934), described some of the particulars of some of the principal French and British electrical engineering exhibits which were then complete, and also the electrical features of the science section, and on pages 23 to 28 of ELECTRICAL ENGINEERING of July 2nd a full illustrated account was given of the collective exhibit organised by the electric supply companies of London. We now propose to supplement these articles by calling attention to some additional electrical engineering exhibits which we have not been able to describe before, and to give a few further notes on the principal examples of power plant in the Machinery Hall, and some of the more notable cases of the application of electrical power in the exhibition.

We have already referred (ELECTRICAL ENGINEERING, Vol. III., page 931) to the imposing stand of Messrs. MATHER & PLATT



MESSRS. MATHER & PLATT'S STAND IN THE MACHINERY HALL, SHOWING ALTERNATOR DRIVEN BY 800-H.P. KÖRTING GAS ENGINE.

near the entrance to the Machinery Hall, and are now able to give an illustration of the group of machinery exhibited by this firm. Specially prominent is the generating set consisting of a three-phase flywheel alternator, designed for an output of 170 amperes at 2,200 volts 25 cycles at a power factor of 0·8, with its rotor mounted on the crank shaft of a fine twin-cylinder two-cycle gas engine of the Körting type, capable of developing 800 B.H.P. continuously at 107 r.p.m., with a gas supply equivalent to about 140 B.Th.U. per cubic foot. The other exhibits, including examples of the Zoelly turbine, have already been alluded to.

In our description of the collective electrical exhibit, we referred briefly to the apparatus exhibited by the REASON MANUFACTURING CO., of Brighton, in the reception room, and are now able to give some further particulars of this company's exhibit. The firm point out that the advent of the metal filament lamp renders accurate registration of small currents a matter of even more importance than it was before, and that with the possible initial falling-off of revenue from private lighting that may occur before the full effect of their benefit to the supply industry is apparent, increased economy in the meter department of central stations will be sought for. It is claimed that the new type of Reason electrolytic meter materially reduces such expenditure, and a full complement of patterns of this description of meter are on view. These are hermetically sealed, and the entire absence of clockwork is claimed to be an important factor in keeping down the cost of maintenance. Notwithstanding the use of glass containers, they are in no way more fragile than the customary motor-driven meters, with their train of fine glass-hard steel pivots and gear-wheels. The present design of Reason electrolytic meter has passed the tests of the Board of Trade, and embodies improvements which have overcome the troubles experienced with some of the early electrolytic meters. The electrolytic chamber is a glass bulb containing electrodes of mercury separated by an annular glass partition. The gases given off rise to the top of the bulb and cause the liquid to be displaced and to drive down an indicating column of mercury in a U tube. The action can be studied in a special demonstration meter with the case removed, which is effectively illuminated from behind. In addition to these meters, the Reason Co. show a selection of the manufactures for which they are noted, and which includes prepayment meters, maximum demand indicators of thermal and electro-magnetic type, time switches, &c. They also have a series of their different patterns of arc lamps, five of which, burning in series off a 500-volt circuit, are to be found over the motor section of the Supply Co.'s exhibit, and two miniature enclosed arcs, run off a 220-volt alternating circuit, are mounted on the two pillars which flank the entrance of the reception room. The centre of the Reason Co.'s main exhibit is occupied by a glass-case containing test-room and other apparatus designed by Mr. Clark Fisher, amongst which is a specimen of the compensating type potentiometer with which his name is connected, and now solely manufactured by the Reason Co. under his supervision.

Another stand forming a part of the collective exhibit of the electric supply companies of London, to which we have only referred briefly, is that of the WESTMINSTER ENGINEERING CO., of Victoria Road, Willesden Junction. On this stand are exhibited samples of the firm's enclosed arc lamps, consisting of the brake-feed pattern as used on the

Digitized by Google

Central London Railway, Great Western Railway, Metropolitan Railway at Baker Street and South Kensington, also by the General Post Office. A small enclosed lamp of a slightly different pattern, taking a current of 3½ amperes, and particularly suitable for lighting small shops, corridors, waiting-rooms, &c., is also shown. A lamp of this kind, fitted with a silk shade, hangs in the middle of the stand for the general lighting of the exhibit, and has a very pleasing effect. The display also comprises a number of "Westminster" photographic arc lamps, the speciality being a large lamp burning singly on a 500-volt continuous-current circuit. The arc in this lamp is about 6" long, and the actinic power of the light is very high. A half-size model of a very handy printing frame, with arc lamp and light shade on the top, is shown. A lamp and frame such as this enables the photographer to do the whole of his printing quite irrespective of the state of the weather; in fact, we are told that photographers who get used to printing by artificial light are often inclined to give up daylight altogether, the exposures being so much more easily managed by artificial light. Another object of interest on the stand is the firm's new pattern limit switch. This switch is for use in places where, for one reason or another, it can take the place of a meter; for instance, in large blocks of flats or offices, it is found convenient by the Supply Co. to put one large meter at the point of entrance of the supply, and a limit switch to each tenant of a flat or offices, the tenant is then charged so much per annum for current, his maximum not to exceed a specified amount; if this maximum is by accident exceeded, the limit switch operates by opening and closing the circuit, so causing the lamps to blink violently until the current is reduced to the normal value. The arrangement of the switch is shown diagrammatically in the accompanying figure. When the maximum current is exceeded, the armature

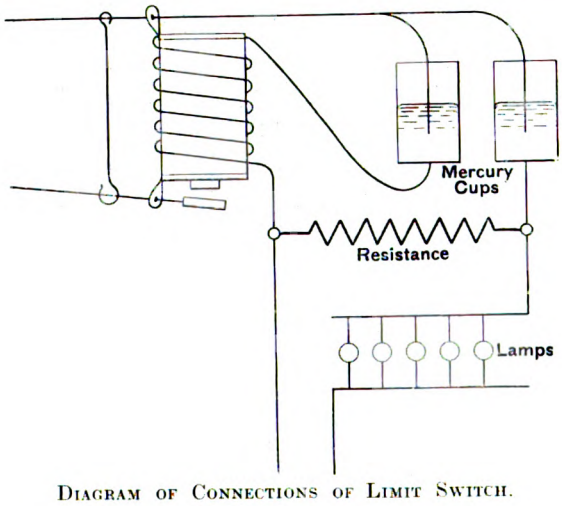


DIAGRAM OF CONNECTIONS OF LIMIT SWITCH.

is pulled up and the forked contact arm is jerked sharply out of the mercury, breaking the main circuit. The current at once takes the alternative path through the resistance, and the lamps are dimmed. As no current now passes round the magnet, the armature falls and the forked contacts dip again into the mercury. This continues till the current is reduced by switching off the excess lights. The particular novelty of this switch is the shunting resistance, which is found necessary in order to make it suitable for use with metallic filament lamps. Such lamps have a low resistance when cold, and take a large momentary current when switched on. It will be seen that, without the resistance, if the switch is started by excess of such load the lamps will be momentarily extinguished, and on making contact again there will be a rush of current, so that a great part of the load must be taken off before the switch would stop working. The by-pass resistance gets over this difficulty by dimming the lamps only instead of extinguishing them. A number of photographs are shown illustrating work done by the "Westminster" photographic lamps, and also illustrating other of the manufactures of the company, which include dynamos, motors, electric welding machinery, electric ventilating fans, switchboards, &c.

An exhibit in the furnished flat, forming part of the collective electrical exhibit, which we did not refer to in our previous article is the small table lamp which is to be found in the bedroom on a small table by the bed, and is represented in the illustration below. This table lamp has been brought out by the LONDON ELECTRIC TRANSFORMER CO., of 10 City Road, E.C., and is a modification of the "Adapter Transformer," which was fully described on page 698 of ELECTRICAL ENGINEERING, Vol. III. The main object of these transformers is to render possible the use of low-voltage, low-candle-power, high-efficiency metal-filament lamps on high-voltage supply circuits. The continuous capacity of the standard type is somewhat over 20 watts, and they are wound for transforming down from a primary pressure of 100 to 250 volts to a secondary pressure of 25 or 50 volts. The table lamp illustrated contains one of these transformers in its pillar, and is also fitted with the turn-down device described

TABLE LAMP CONTAINING SMALL TRANSFORMER FOR LOW-VOLTAGE METAL FILAMENT LAMP.

in the previous article. There are three positions: full, medium, and a mere glow. The possibility of reducing the light in this way, with corresponding economy in current consumption, makes the lamp a specially ideal lamp for bedrooms, nurseries, and sick-rooms. A neat switch in the primary circuit renders it unnecessary to remove the socket plug to switch off the light, and the brilliancy is regulated by simply rotating the lamp shade. The transformer may be detached from the base and used suspended from an ordinary lamp socket if desired. In the case of house installations with a high-voltage supply, in which electric fans and heating appliances are employed, a general change over of the whole house circuit to 25 volts would be inadmissible; with the aid of these "adapter" transformers, 25-volt metal filament lamps can be used, the reduced consumption amply justifying the cost of the transformers.

A stand, forming part of the collective exhibit, which has been completed since the press view upon which our article of July 2nd was based, is that of Messrs. DUNCAN, WATSON & Co., of 102 Charing Cross Road, who have a display of high class metal work as applied to electric lighting, including some artistically designed fittings in various styles and ornamental flush switch and bell push plates with door furniture to match. Another exhibit is a form of self-contained electrically-driven vacuum cleaner for home use, known as the "Aspirator." This is compactly arranged in a small wooden cabinet.

One or two new items have also made their appearance in the reception room. Among these we noticed a board erected by SIMPLEX CONDUITS, LTD., forming a display of examples of every possible variety of component parts and fittings for their well known and very completely thought out system of conduit wiring. Samples are also shown of the Simplex metal filament lamp.

Another new exhibit in the reception room is that of the PASTIAN METER COMPANY, which consists of a board upon which are shown seven examples of various sizes of the well-known Pastian electrolytic meter.

Another new electrical exhibit in the Machinery Hall close to the collective display, although not actually forming a part of it, is a 14-cell accumulator battery of a capacity of 120 ampere-hours, manufactured by the HART ACCUMULATOR CO., which is shown on the stand of Messrs. JOHN BARKER & Co., alluded to in our previous description in connection with the Kennedy patent pipe bending machine.

Digitized by Google

In addition to the exhibit relating to "Liconite" cables on the stand of Messrs. GEIPEL & Co., in the Machinery Hall, are several examples of a new pattern of the Geipel rapidity steam trap, including a model showing the actual working parts in section. In this trap, which differs slightly from the earlier patterns, the brass tube, which constitutes the inlet and should be connected to the vessel to be drained, is at the bottom of the trap. The iron tube, which constitutes the outlet for the discharge, is at the top as in the ordinary Geipel trap. The valve is held normally on its seat by the steam pressure combined with the pressure of a light spring. When the trap is cold or full of water, the valve is depressed from its seat by the valve spindle, which abuts against the end of the lever. When steam enters the brass tube, the latter expands and moves the valve casing upwards. The steam pressure and light spring then close and hold the valve tight until water has again entered the brass tube and cooled it, upon which the brass tube contracts and moves the valve casing downwards until the valve spindle impinges on the valve and forces it open. As soon as the valve is open the rush of water, so to speak, forces or wedges the valve upwards, thus making the large opening which gives the rapid discharge. The valve is separate from the valve spindle and is therefore not held fast by the friction of the stuffing box; further, being provided with veins, it is caused to rotate whilst discharging, and consequently to grind itself in at each discharge so that the seat is kept in good order. The action of the trap is such that there is no dribbling, but as soon as ever the trap commences to discharge the valve is forced well open; a sharp blow-through then occurs until all water is discharged, when the trap is as suddenly shut. Examples of the traps are seen at work on the steam range supplying the Parsons turbo-generator.

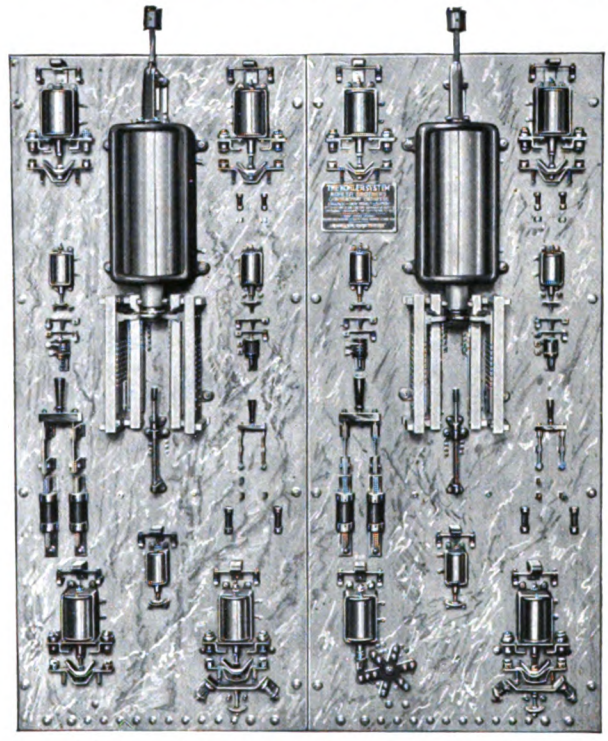
An effective stand in the centre of the portion of the Machinery Hall running across between the British and French wings is that of the UNITED FLEXIBLE METALLIC TUBING CO., LTD., represented in the accompanying illustration. The struc-

DISPLAY OF FLEXIBLE METALLIC TUBING.

tural part of the pavilion and the arches surmounting it are most effectively arranged from samples of the firm's well-known flexible tubing composed entirely of metal without any other packing material, and suitable alike for high temperatures and pressures, or the conveyance of oils or greasy liquids which quickly attack indiarubber and similar material. Particular attention should be paid to the arrangement of the incandescent lamps outlining the arches, the wiring of which is entirely enclosed in flexible metallic tubing used in conjunction with special lamp holders.

A few new electrical exhibits have made their appearance in the French section since our last description, but even now there are many incomplete stands in this part of the exhibition. Near the entrance is a stand of the SOCIÉTÉ ALSACIENNE DE CONSTRUCTIONS MÉCANIQUES, of Belfort. This well-known firm exhibit a series of motors exemplifying their continuous current and three-phase standard patterns, and also a large three-phase automatically-controlled booster transformer with movable windings. Another object of special interest on the stand is a 50 h.p. single-phase traction motor, complete with gearing for 500 volts 25 cycles, and a normal speed of 500 r.p.m. Another new stand completed recently in this section is that of a firm styled the FRANCO-BRITISH ELECTRICAL CO., who show examples of a very effective system of decorative lighting with small incandescent lamps arranged in festoons with glass beads and small transformers for enabling low voltage metal filament lamps to be used on alternating currents of the ordinary supply voltages.

An important application of electric driving is represented by the large octuple web perfecting press manufactured by Messrs. R. HOE & Co., for the *Daily Mail*, and exhibited working in the pavilion of that newspaper. The press, which is capable of producing 100,000 eight-page papers per hour, is operated by the "Kohler" electrical continuous-current control system. The equipment, which was supplied by Messrs. KOHLER BROS., of 56 Ludgate Hill, E.C., consists of two 60 h.p. and two 10 h.p. motors, and the standard "Kohler" four-motor controller with sixteen push-button control stations at various points about the press. The main 60 h.p. motor is coupled direct to the press-shaft, and the auxiliary 10 h.p. motor is connected to this press-shaft through a worm gear and free wheel. The auxiliary motor



KOHLER FOUR-MOTOR CONTROLLER FOR THE "DAILY MAIL" NEWSPAPER WEB PRESS.

is used for operating at slow speed when dressing the press and leading in the paper web. The main motor takes up the load and over-runs the small motor when operating at printing speed.

The whole of the manipulation of the controller is carried out from any one station, permitting the operator to start, stop, run up the speed, or slow down, and also to lock the controller at any given speed or to lock it at the stop position. Thus absolute control of the movements of the press is placed in the hands of the operator from the point where he is working. For example, when putting on fresh plates, &c., the operator can make his adjustments and move the press just exactly to the point required without leaving his position, and when in that position he can lock the control so that the press cannot be moved until he has completed his task. This printing press can be used either as a whole to produce papers of 24 to 32 pages, or as two separate presses producing papers of 4 to 16 pages. Therefore, two separate motors and control outfits are provided, and these can be run either as two sets or as one set; in the latter case the motors and push buttons are automatically paralleled when the mechanical clutch connecting the press is placed in gear. The accompanying illustration is a photograph of the four-motor controller used with this press, and a photograph of one of the push-button control boxes is reproduced below. The chief features of the "Kohler" system of control are as follows:—For putting on blankets or plates, the cylinders can be brought to any desired

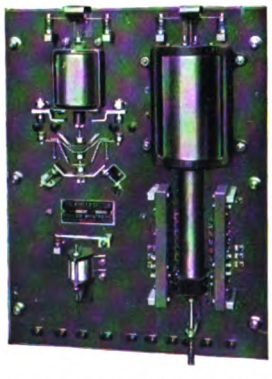
Digitized by Google

position, and a movement of only $\frac{1}{8}$ of an inch can be made. Again, the speed of the plate cylinders can be varied from ten revolutions per minute through twenty intermediate speeds to the maximum speed. While a press is being made up, and a pressman is working on any part of it, he can make it impossible for anyone to start the press by pressing the "safe" button. To start the machine he must press the "run" button. The "safe" button only prevents any alterations being made to the existing conditions; thus, pushing this button when running at a certain speed prevents increase or decrease of speed. To accelerate, the "on" button is pressed, and to slow down the "off" button is pressed. Pushing the "stop" button stops the machine in a few seconds. Whenever the machine is stopped the controller automatically returns to the starting point. The control circuit, including push-buttons, solenoids, &c., is operated at the motor voltage off the supply circuit. The control boxes are well insulated, and a resistance are connected in series with the solenoids to limit the control current to the necessary value.

The press is first started up on the small 10 h.p. motor through the worm gearing by pressing the "run" button, which releases a plunger, seen in the centre of either of the boards illustrated. The plunger descends slowly, cutting out the starting resistance of the small motor; its descent can be arrested by pressing the "safe" button. If allowed to descend further, the small motor reaches its maximum speed, and the large 60 h.p. motor takes up the load. The contacts behind the plunger belong to the starting resistance of the small motor, and the side contacts belong to that of the larger motor. On pressing the "off" button, the plunger rises slowly, reducing the speed and eventually, unless arrested, transferring the load on to the smaller motor in case it is desired to run at a slow speed or to move the rollers to any particular position. The starting resistances for the large motor would have to be abnormally heavy if it was necessary to run this at the slow speeds; and, moreover, the small and certain movements rendered possible by the use of the small worm-geared motor would be impossible to attain with the large motor only.

The other solenoids on the boards illustrated are connected with the control system, and means for paralleling the control circuits of the two machines and the four motors is also provided. The main switches, shown in the bottom right-hand corners of the two boards, are controlled by the "stop" button and the overload and no-voltage cut-outs. When the main switches open, they short-circuit the motors at the same time, which brings the machines to rest in one or two seconds. The power to drive this press, as well as that for lighting the pavilion, is obtained from a 95-kw. E.C.C. continuous-current generator driven by a two-cylinder Diesel oil engine adjacent to the press.

Printing machinery under electrical control on the "Kohler" system can also be seen at the stand of Messrs. BEMROSE & SONS, of Derby, who are producing there the daily programmes, &c., for the exhibition. The plant consists of two flat-bed printing machines, two folders, two guillotines, and the necessary



KOHLER STANDARD CONTROLLER FOR FLAT BED PRESS.

PUSH-BUTTON OPERATING SWITCH, AS USED ON THE "DAILY MAIL" PRESS.

wire-stitching machines for binding the programmes. All these machines are driven by Westinghouse continuous-current motors. The two printing presses and folding machines are operated by means of "the Kohler System" of multiple push-button control. On each of the four machines there are two control stations. These stations give absolute control, and the machines start immediately the "On" button is pressed and come to rest immediately the "Stop" button is pushed in; the action is so far under control that the machine tables can be moved half an inch at a time. They can also be accelerated up to full speed in any given time, slowed down gradually to dead slow, or stopped immediately. The board illustrated below is the standard type for operating flat-bed presses. It contains a plunger and single set of contacts, which act in a similar manner to those of the larger controller. The main switch, armature short-circuiting switch, and overload cut-out are also visible. No matter how the operator may handle his push-buttons, he cannot harm either the machine he is operating or the motor driving it. The controllers for several machines may be grouped together in one place quite remote from the machines, and are thus not subject to the abuse or damage from vibration and dust, but, on the other hand, are so placed that they can have complete and efficient supervision without holding up the presses.

This system of control has been in use at the printing offices of the London *Morning Post* and the *Manchester Chronicle* for some four years, and it is now being adopted by the *Daily Mail*, *Daily Mirror*, and *The Times* in this country, by *Le Matin* in Paris, by the *Rotterdamsche Courant* in Holland, and in America by many of the leading newspapers and printers. We understand that there are over five hundred of these outfits in use, and that many have been in use for several years, giving very satisfactory results as to expenses of maintenance.

In the *Daily Mail* Pavilion is also to be seen a complete set of the Pollak-Virag writing telegraph instruments. The principle of the receiving and writing instruments is as follows: The movement of a small mirror is controlled in two directions at right angles to one another by two electro-magnets; this mirror reflects a ray of light on to sensitised paper. Two movements in either direction are possible; the larger movement is produced by sending current through the magnet winding for a slightly longer period. By combining these four movements, the ray of light can be made to write in very uniform and easily legible characters. The sending instrument consists of the perforator (a form of typewriter) and the transmitter proper. A strip of paper is passed continuously through the "perforator," and the operator uses the buttons in the ordinary way. For each letter a group of small and large holes is punched in the strip. When the strip passes through the transmitter, these holes allow current to flow for short and long intervals respectively, which produce corresponding movements of the mirror. Current through both "vertical" and "horizontal" electro-magnets simultaneously produces a sloping line. The speed of operation of the perforator is, of course, the same as that obtained with an ordinary typewriting machine, but the speed of the transmitter and receiver is some 40,000 words per hour. The sensitised paper, after being exposed to the action of the light ray, is passed through a developing bath and finally a fixing bath incorporated in the body of the instrument, so that messages are delivered written and legible. The instruments shown are connected by a combined resistance, inductance and capacity corresponding to a distance of 400 miles. Two wires only are needed to connect the instruments.

The Korn system of reproducing photographs at a distance is represented by a complete set of transmitting and receiving instruments at the *Daily Mirror* Pavilion. This system, which depends for its action on the alteration of the electrical resistance of selenium under the influence of light, was described in ELECTRICAL ENGINEERING, Vol. II., page 766.

Disputed Tramway Coils.—At the Clerkenwell County Court on Thursday last week Messrs. D. Santoni & Co. (1906), Ltd., sued the Farringdon Engineering Co., of 29 Red Lion Street, Clerkenwell, for £49 16s. 10d., the price of 314 armature coils for use on the Birkenhead tramway system. The defence was that when tried upon the tramways in question the coils short-circuited and would not bring the cars out of the yard. The hearing before the County Court Judge lasted nearly two days, and the Judge decided in favour of the defendants, expressing the opinion that the coils supplied were not reasonably fit for the purpose of tramway traction.

A Works Manager's Salary.—In the Birmingham County Court last week Mr. J. H. Koeller, late works manager to the General Electric Co., Ltd., at Witton, sued the company for £100 alleged to be due to him as a bonus. The plaintiff was engaged in 1906 at a salary of £700 per annum, with a bonus to be fixed at the discretion of the directors. In the first year he received a bonus of £100, but subsequently complained to the resident director of the company, Mr. M. Railing, that, as he had been receiving £900 per annum in New York, he could not in justice to himself remain in England for less. He claimed that it was then verbally agreed that his bonus should be increased to bring his salary up to £900 a year, but he had only received £100, leaving a balance unpaid of £100. For the defence this verbal agreement was denied. Judgment was reserved.

ELECTRICAL TRANSMISSION FOR MAIN MARINE PROPULSION

AT the Congress Hall of the Franco-British Exhibition on Saturday evening, at a special meeting of the Institute of Marine Engineers, Mr. W. P. Durtnall read a Paper on the generation and electrical transmission of power for main marine propulsion and speed regulation. The Paper dealt in a general way with the application of the "Hart-Durtnall" three-phase electric power transmission system (see ELECTRICAL ENGINEERING, Vol. I., page 147) to marine propulsion, and sought to emphasise the great possibilities of electrical power transmission and speed regulation as applied to steam propelled vessels, and the economies obtainable. The steam turbine for marine propulsion has secured a very strong hold, but in this case it labours under a few but important disadvantages. First, when it is direct coupled to the propeller, it has to be designed to run at very low speed in order to permit of the use of a propeller of high efficiency, consequently the weight per B.H.P. developed is increased to a very large extent, and owing to large diameter of rotor and casing, proportionately large blade clearance must be allowed in order to meet the conditions of expansion and contraction, &c., with consequent higher steam leakage and consumption per horse-power developed. Other disadvantages of the direct-coupled steam turbine are the difficulty of reversing for manœuvering and going astern, and the lack of economy in steam when working below full load and speed. This inconvenience, although of perhaps little importance with steamships making long continuous runs, is very important for those making short voyages, starting and stopping, and manœuvring in and out of harbour several times a day, or for ships of war, in battle or manœuvring in squadrons, and in order to get these very necessary qualities, separate astern turbines have to be installed, but with only generally about one-third the ahead power, and these usually only applied to two out of three or four shafts as the case may be.

Mechanical gear has been tried in connection with small-power turbines, but the results, generally speaking, have been far from satisfactory, on account of the great noise and heavy cost of up-keep. Electrical power transmission has, however, the very elements that are required in order to take advantage of high-speed turbines; thus saving turbine weight and also securing high economy in steam by utilising these to drive electric generators, the current so generated being used to supply low-speed electric motors, coupled to high efficiency, moderate speed, and large-bladed propellers. Further, this method of power transmission does not necessitate the cost of installation or operation of reverse turbines.

Owing to the very fine control which is possible, advantage can be taken of complete operation from the bridge, or other suitable position, by means of motor operated switches, and the main circuit need only be broken under no voltage conditions.

In the author's opinion, electrical power transmission can be only successfully carried out by means of polyphase alternating currents with synchronous generators, and squirrel cage induction motors, not only on account of the great simplicity of these machines, their low cost, and low weight per horse-power developed, but also because the use of continuous-current machines with commutators and brush gear would be next to impossible for such high powers as would be necessary.

The electrical efficiency of turbo-alternators varies from 85 per cent. to 98 per cent., and their weight per kilowatt output for continuous rating between 35 to 22 lb., according to speed and other circumstances, while the steam consumption per kilowatt hour in 7,500 kw. sizes at, say, 750 r.p.m., running condensing and at 160-lb. steam pressure, with 150 degrees superheat at the stop valve, with about 27½-in. vacuum, is about 13·5 to 14 lb. (including auxiliary plant), while a 2,000-kw. set running at 1,500 r.p.m. under similar circumstances consumes about 15·5, and it is also interesting to note that a 500-kw. set at 3,000 r.p.m. uses only 23 lb. of steam per kilowatt hour.

It is quite within the range of possibility to design and construct three-phase squirrel-cage motors for marine work, of from 1,000 to 10,000 horse-power, which would weigh from 35 to 20 lb. per horse-power developed, and this for continuous rating and without sacrifice of any efficiency, which would in these cases be about 93 to 97 per cent.

Let us assume that we wish to know what will be the steam capacity of the boilers for a vessel fitted for electrical transmission. For four propellers each requiring to rotate them, 1,000 B.H.P. at 250 r.p.m., the motors would be of the polyphase induction type, with squirrel-cage rotors, and with stators wound for full, half, and quarter speeds. The generators would in this case consist of two turbo-alternators and exciters capable between them of generating and supplying 3,250 kilowatts, and running at a speed of 1,500 r.p.m. with steam at, say, 150-lb. pressure and 150 degrees F. superheat. These alternators would be, say, two-pole machines; therefore, if the motors are wound for 12 poles (for top speed) it will be equal to a 6 to 1 reduction. For half-speed, the second winding would be arranged for 24 poles, 12 to 1 reduction with two sets of windings in parallel, and for quarter speed this winding would be arranged for 48 poles, 24 to 1 reduction; the synchronous speeds would thus be full speed 250, half speed 125, and quarter speed 62½ r.p.m.

For the top speed the above turbo-alternators would be coupled up in parallel, and when supplying the motors with current would generate 3,250 kw., and the consumption would be, say, 16 lb. per kilowatt, or 50,400 lb. of steam per hour, or 15 lb. per shaft horse-power, which compares, in my opinion, very favourably with what would be required with direct-coupled turbines working under similar speed and circumstances, which would be more of the order of 22 lb. per shaft horse-power, or 88,000 lb. The difference in steam consumption is 36,000 lb. per hour, representing a saving of no less than 41 per cent. in boiler capacity. Now, at half speed, we will close down one of the turbo-alternators altogether, and we shall probably only require, say, 600 shaft horse-power at this speed; therefore, I will estimate the efficiency of the motors at this half-speed and load 60 per cent.—740 kw., the turbo-generator would use, say, 24 lb. of steam per kilowatt hour with this load, but would run at top speed, although at half vessel speed, and this is equal to 17,760 lb., while the direct-coupled turbines would each run at half-speed, and the consequent steam consumption would be not less than 47 lb. per shaft horse-power, or 28,200 lb. of steam. Under these circumstances there would be a saving of no less than 11,880 lb. per hour, or 37 per cent.

Assuming these estimates to be approximately correct, it may be asked, what will be the relative weights of the two systems? so we will take first the electrical equipment :—

4,000 B.H.P. at 35 lb. per h.p. developed, say	62½	tons.
Conductors, switchgear, &c.	6	,,
Two turbo-generators as above . .	70	,,
Condenser for above	19	,,
Steam, piping, &c.	13	,,
Air pump and motor	6	,,
Circulating pump and motor . . .	7½	,,
Total	184	tons.

The weight of the direct-coupled turbines and part of the propeller shafts, shaft tunnels, &c., including condenser, steam-pipes, &c., air and circulating pumps—which would have to be arranged to deal with the 88,000 lb. of steam—would be at least (taking the speed of the turbines at 250 r.p.m.) 148 tons, showing that the electrical machinery would be about 25 per cent. heavier; but it is here necessary to point out that that only applies to the plant from stop valve to propeller shaft connections.

We will now look into the possible saving in operating costs and weight at the other side of the stop valve. Let us take the data that have been published, as regards the weights of cylindrical boiler, stoke-hold equipments, &c., which are as follows, when taking reciprocating engine vessels into account :—For good cylindrical boilers, including small and large mountings, fire box and funnel (boiler empty) with forced draught, pipe-work, including all pumps, water, steam, and exhaust pipes, gratings, platforms, &c., the weight per I.H.P. in boiler-room reaches 180 lb. Therefore, the weight of the boiler-room equipment of a vessel in which would be installed, say, two reciprocating engines running condensing would approximately be as follows :—

Taking 180 lb. boiler equipment weight per I.H.P., then 4,700 I.H.P., with a mechanical efficiency of 85 per cent., would equal 4,000 B.H.P., and would account for a weight of 377 tons, and in order to get at the steam consumption per ton of boiler weight, we will allow, say, 16 lb. of steam used per I.H.P., including steam required for auxiliaries and losses due to radiation, &c., or a total of 75,200 lb. of steam, or 200 lb. of steam per hour per ton of boiler-room equipment. Under these circumstances the boiler-room equipment would weigh for the 52,000 lb. of steam that will be required for the electrically-driven vessel 260 tons, while for the direct-coupled turbine-driven vessel the boiler equipment would weigh

Digitized by Google

not less than 440 tons, or a saving in weight in boiler-room equipment for the same propeller h.p. of not less than 180 tons, or 40 per cent.

Now, as regards coal consumption, and comparative saving in this direction, we will take it that with hot feed, clean flues, and with good Welsh coal, it is possible to evaporate, say, 10 lb. of water per lb. of coal burnt, so that we have in the direct-coupled turbine vessel a coal consumption of 8,800 lb., and in the case of the electrical vessel 5,200 lb., or a saving of 1·6 tons per hour, which equals in a ship running for six days a net saving in favour of the electrical scheme of no less than 230 tons. This important matter will be surveyed with somewhat close interest by cargo vessel owners, as it may be at the same time observed that the propellers are run at about the same low speed as is necessary and usual in these slow vessels, in order to secure economy at the propeller.

The Paper will be discussed at a future meeting of the Institute.

CORRESPONDENCE

ACCUMULATORS FOR PEAK LOADS.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—It is with much reluctance that I trespass upon the hospitality of your columns, but it is to correct a mistake of some considerable importance, and one that tells very adversely against batteries, and this must be my excuse. The comment of practically everyone who has hitherto criticised my paper has been that the use of cells is doomed to discontinuance directly any station acquires a decent load factor. In the case of the large majority of our municipal systems, it would be most unsafe to predict that the load factor will exceed 30 per cent. in the course of the next ten years. If, then, it can be shown that, as far as *fixed* charges are concerned, the battery can compete with steam additions, even where there is a good load factor, the only question remaining is whether, in the matter of *running* expenses, this saving is not wiped out by the inefficient battery. An analysis of the Neptune Bank mid-winter peak for 1903 (see Merz's paper, April, 1904) shows that, by putting in a battery on a three-hour rating, it would be practicable to take up 40 per cent. of the peak. The capital cost would be £15 per kilowatt, and the annual *fixed* charges £2·4 per kilowatt of maximum demand per annum, as against £4·6 per kilowatt, with reciprocating engines, or, say, £4·2 per kilowatt, with turbines to the battery curve, as already explained at Nottingham. It may here be remarked that it is the high value of *other* fixed charges than capital costs which tells against steam. The *running* charges will also be less (although the load factor at Neptune Bank must have been quite 50 per cent.), because the battery enables certain engine and boiler units to be shut down altogether on account of the all-night load being so much less than the day load. The diagram given with my paper shows a net saving of some 4,750 tons of coal per annum for a station which is mostly a lighting station. On a station with a large power load this would no doubt be considerably reduced; but there would certainly still be a saving, even where steam turbines were employed, on account of the reduced number of boilers under commission. Surely there are many municipal stations that have yet to beat the power load possessed by Neptune Bank in 1903-4.

Is it too much to hope that the above simple example, which anybody can check for themselves, will at least cause engineers to consider whether the continuance of the use of batteries does so entirely depend on the obtaining of a power load, and whether the all-night load, and the sizes of steam units employed, do not have something to say in the matter?

Yours faithfully,
A. M. TAYLOR.

Avondale, Ashfield Road, King's Heath.

AUTOMATIC STOKERS.

To the Editor of ELECTRICAL ENGINEERING.

DEAR SIR,—In your issue of the 9th inst., you published the report of a very interesting lecture delivered by Mr. H. Richardson, Chief Engineer of Dundee, at the thirteenth Convention of the Incorporated Municipal Electrical Association at Nottingham, on the subject of "Design in Generating Stations." In the discussion that followed the reading of Mr. Richardson's Paper, Mr. Brydges, Borough Electrical Engineer for Eastbourne, in his reference to the underfeed type of stoker, for which he has an avowed preference, stated that he considered this stoker had a great advantage over the chain grate, as it would burn practically any sized coal, including smudge and duff, and that he did not think there was any other chain grate or automatic stoker that would burn this coal satisfactorily. He had also found that the repairs were not as large as they were with other types.

Now, Sir, as the oldest and premier firm of stoker-makers in this country, we would suggest to Mr. Brydges two or three points for his consideration in connection with the system of underfeed stoking He has certainly made large claims for the system, while he has omitted to point out any of its drawbacks. For instance, it is well-known by those who use this type of machine that nearly one-third of the furnace grate is taken up with the coal feed, and that the air requisite for burning the coal has to be passed through the mass of fuel which has been rammed semi-solid by the action of the underfeed ram, so that little available air for combustion can percolate through this portion of the grate. For coal combustion purposes, therefore, the underfeed system gives only two-thirds of the grate surface, which ought to be available in the furnace. Again, owing to the disposition of the fire-bars in the underfeed machine, it has been objected by the supporters of the overfeed type of stoker, that the cleaning action is not effective, and the bars gradually accumulate clinker and ash at the two sides of the furnace, which has to be cleaned out by hand at the end of a period depending upon the amount of clinker and ash in the fuel.

The principle of action of the underfeed suggests lighting a coal fire at the top in an ordinary grate. It is common knowledge that if you light a fire in this way it takes a very long time to burn up and glow brightly, because the hydrocarbon gases distilled from the coal, coming through the incandescent fuel on the top, have a greater affinity for the oxygen in the air than the carbon, so that the temperature is lowered at the very point where it should be highest, and it is difficult to prevent a certain amount of carbonic oxide being formed, with the consequent lowering of the furnace temperature and loss in efficiency The underfeed machine was originally constructed in America with a view to burning anthracite coals, and it is an excellent machine for this purpose—anthracite containing as a rule a very small proportion of ash or clinker—but with the bituminous fuels generally used, the underfeed system for all practical purposes is nothing like so efficient as the overfeed type.

We may here point out that, apart from these considerations, it is a slow process getting up steam on the boilers with underfeed stokers. The rapidity with which steam can be produced is certainly a vital element in steam economy. It is also necessary to remember that a fan and air ducts are necessary with the underfeed system, which considerably adds to the initial expense as well as to the costs of maintenance. A consideration of these principles will, we think, result in a conviction that the disadvantages resulting from the adoption of the underfeed stoker are very serious. Of course, we are not here referring to any special make of underfeed machine, but to the underfeed principle. With regard to Mr. Brydges' observation that he did not think any other automatic stoker, chain grate or otherwise, would burn smudge and duff, the lowest grades of coal, satisfactorily, in answer to this observation we can only say that if Mr. Brydges will give us the opportunity we shall be very pleased to conduct him personally over leading boiler-houses in all parts of the country where smudge and duff and other pit rubbish are the only classes of fuel burnt, and where the thermal efficiency obtained is very considerably higher than is possible to the underfeed type. Again, with regard to the chain grate, we should like to ask Mr. Brydges whether he is alluding to the old type of grate which threatens to become obsolete, if it is not altogether so at the present time. We could certainly assist him in compiling a list of the disadvantages of that ancient machine, but at the same time we should like to introduce him to the latest improved class of stoker, in which the old disadvantages are altogether abolished and a number of marked advantages introduced, that now render the chain grate stoker one of the most useful on the market. It is quite possible with this new type to burn very low-grade and cheap fuels and yet to obtain a high evaporative duty from the boilers, but perhaps Mr. Brydges will give us the opportunity and the pleasure of showing him for himself these new grates in operation, doing regularly far more than we intend to claim for them, and by a recent installation bringing down coal costs in one of the most famous electricity works in Great Britain.

We are, dear sir,
Yours faithfully,
For ED. BENNIS & CO., LTD.,
ALFRED W. BENNIS.

28 Victoria Street, S.W.

Wireless Telegraphy.—The Mersey Docks and Harbour Board have decided to arrange for the hire of two sets of Marconi apparatus, one for the North-West Lightship and the other for Bidston Lighthouse and Telegraph Station. The hire is to be for one year certain, subject to three months' notice at the expiration of that period.

ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY

IN the German Patent 199265 (1908), W. A. Hirschmann describes an electrical method for maturing and ageing wines and spirits. A very high potential induction current is caused to pass through the fluid, a spark gap or vacuum tube being placed between the inductor and the fluid. The electrodes which carry the current are placed deeply into the liquid, and as far apart from each other as possible, so that the whole of the fluid is under the action of the electrical stress. It will be interesting to know whether this process is as satisfactory as the process of ageing and mellowing of wines and spirits by means of a current of ozone.

We understand that interesting experiments are being carried out at Marseilles Exhibition in connection with the forcing of early fruit and vegetables, particularly asparagus and strawberries, by means of electricity. Instead of heating the forcing frames by means of hot air or steam as usual, conductors are passed through the soil, being buried at various depths and through these currents varying from 1½ to 5 amperes are passed. The forcing frames are kept separated in order that parallel experiments may be carried out.

In the *Journal of Physical Chemistry*, **12**, 155, H. J. Barnes and G. W. Shearer describe a hydrogen peroxide cell. They first recapitulate previous work upon the subject by H. M. Tory and G. H. Cole upon the behaviour of aluminium and magnesium electrodes in water which contains dissolved air, oxygen, or hydrogen peroxide. Many metals show a potential difference when one electrode, the anode, is placed in oxygen free water, and the other, the cathode, in water containing dissolved oxygen, the E.M.F. being particularly great (about 1 volt) in the case of aluminium. When two electrodes of different metals are employed, the action is additive. For example, aluminium and magnesium in oxygen-free water give an E.M.F. of 0·02 volt, but when oxygen is led through the water the E.M.F. rises to about 1 volt. The best cell, that is, the one which gives the highest potential, is $Mg \mid Al_2(SO_4)_3 \mid Al$. When hydrogen peroxide is added to this cell the potential rises to 1.7 volt, and ultimately to 2·1 volts. On closing the circuit the E.M.F. first rose to a maximum, and then gradually fell off. Fresh addition of hydrogen peroxide again caused it to rise to the maximum value. With an outside source of current the cell behaved in a normal manner, in so far as the E.M.F. rose to a maximum when the cathode was aluminium, and fell to a lower value when the anode was of this metal. This explains the rise to a maximum on closing the circuit, but hardly explains the high value obtained. According to Bancroft, this may probably be due to the formation of hydrogen peroxide when aluminium is placed in water containing oxygen, thus :—

$$2Al+6H_2O+6O=2Al(OH)_3+3H_2O_2.$$

The authors actually find that hydrogen peroxide can be detected in oxygenated water in which aluminium has been allowed to remain for some hours. The reaction is particularly strong when aluminium foil is made the anode and a current passed, but when the anode is platinum and the cathode aluminium, then no hydrogen peroxide is produced. It follows, therefore, that the addition of hydrogen peroxide to the cell with aluminium and magnesium electrodes, simply increases the potential. By electrolysis with aluminium cathodes the hydrogen peroxide is reduced, consequently the quantity decreases, therefore a further addition will bring the E.M.F. back to its original value. Other metals behave in a similar manner to aluminium, particularly iron and zinc. In the case of other metals, however, it was not found possible to prove the formation of hydrogen peroxide, therefore if it is produced the quantity is too small to detect analytically, in spite of the fact that the reactions for hydrogen peroxide are exceedingly delicate.

In the June number of the *Electrochemische Zeitschrift*, F. Schmiedt describes experiments which he has carried out upon the electrolytic oxidation of copper when it is employed as anode in solutions of sodium hydroxide. E. Muller and F. Spitzer think that the oxide produced is Cu_2O_3, and that this is very unstable in sodium hydroxide solutions, consequently it decomposes, and it is therefore extremely difficult to obtain analytical results. Schmiedt has not only analysed the product, but he has measured the oxygen evolved, by which means he was able to calculate how much of the oxygen produced by the current had been used up for oxidising purposes. The loss in weight at the anode was also measured. Taking all these factors into consideration, he thinks that the oxide formed is a mixture of Cu_2O_3 and CuO_2, but that probably also Cu_2O is produced. By increasing the temperature during the electrolysis the amount of oxygen liberated increased, and this was probably due to the instability of the peroxide, which at elevated temperatures breaks up into oxygen and cupric oxide.

In the *Comptes Rendus* (1908), 146 and 329, E. Doumer publishes a note upon the Electrolysis of pure Hydrochloric Acid. He proves that when the pure acid is electrolysed a portion of the water in which it is dissolved is likewise decomposed, and that consequently at the anode oxygen is evolved along with the chlorine gas. The production of oxygen is further due to the direct electrolysis of the water, and not to the liberated chlorine.

ELECTRICAL SCIENCE

British and American

Magnetic Properties of Hadfield Alloys.—In the June *Proceedings* of the Royal Society is an account of an investigation by E. Wilson, V. H. Winson, and G. F. O'Dell into the hysteresis and other magnetic properties of two iron alloys invented by R. A. Hadfield. One was the alloy called "stalloy" (which contains about 3 per cent. of silicon), and the other was a transformer iron called "lohys." The specimens were in the form of rings built up of stampings, and were wound over with primary and secondary coils for the ballistic method of testing. The alloys are found to differ considerably from pure iron in their magnetic nature. For instance, it is well known, from Rayleigh's work, that for Swedish iron the permeability is very nearly constant for all field values between 0·00004 and 0·04 C.G.S. In the case of both these alloys the value of μ rises rather quickly in the range of field values just mentioned. Stalloy is somewhat remarkable in that it very readily yields unsymmetrical hysteresis loops. For example, as an extreme case, the field was reduced from 63 to 0·712 C.G.S. units, and a loop obtained with the latter figure as the maximum H. If in the unsymmetrical loop thus drawn the axis of H is placed so that the coercive forces are equal, the positive and negative values of B remain very unequal, though the positive and negative values of the residual magnetism are equal. This effect persists after some hundreds of reversals, and was removed only by reapplying the larger force and reducing the field slowly through many reversals. The Steinmetz coefficients for both materials have been worked out from the usual definition : ergs lost in hysteresis per cu.cm. per cycle $=\alpha B\beta$, but β was found to vary through a wide range in each of the materials.

Continental

High-Potential Direct Circuit.—The secondary current of an induction coil worked with a Wehnelt interrupter becomes unsymmetrical when a spark-gap is introduced; and when the gap is of any but very small size, the current becomes practically a direct pulsating current. O. M. Corbino, in the *Physikalische Zeitschrift* for June 15th, gives hints for obtaining such currents in a convenient manner. The secondary of a small induction coil is discharged through a spark micrometer and a condenser and inductionless resistance mounted in parallel. The Wehnelt interrupter may be used with small coils if an inductance and pretty high resistance is put in the primary. The current in the secondary circuit is the break current only, and 2,000 pulses per second are easily attained. Instead of a spark gap, a small vacuum tube may be used. It is best to keep the spark-gap so short that the secondary current is only just uni-directional, and that any further reduction of the spark-gap would make it alternating. The current obtained by the author with the aid of a paraffin-paper condenser was 30 milliamperes. With suitable condensers there is no reason why the voltage should not be very high. With two Ruhmer condensers in series the author got as high as 6,000 volts.

Thermoelectric Detectors.—In connection with the employment of crystalline contacts for detecting electromagnetic waves, C. Tissot announces in the *Comptes Rendus* for July 6th that almost any two substances may form a detecting combination without any outside source of E.M.F. The only requisite is that the area of contact should be very small. The further apart in the thermoelectric series the bodies are situated, the better is the effect, and this indicates that the effect is really of purely thermoelectric nature. Such substances as pyrites and manganese dioxide in the form of pyrolusite may be associated with any pure metal, the latter being strongly electropositive with respect to those minerals. On the other hand, the natural sulphide of copper (Chalcasine), as well as the fused artificial sulphide, or selenium and tellurium, are strongly electronegative towards metals. If the contact has a high resistance, the detector must be placed at a ventral segment of tension of the receiving system. If low, at a ventral segment of current. A copper point pressed against copper pyrites is just as effective as a point pressed against tellurium. The reading is done by the telephone.

Repeating Autoballistic Galvanometer.—The method of repetition, in which the same measurable action is exerted at successive throws of the galvanometer in the same direction, in order to accumulate its effects, has not been much used hitherto on account of the difficulty experienced in timing the action properly. A method of doing this is described by A. Guillet in the *Comptes Rendus* of July 6th. Just above the movable weight suspended by the torsion wire is fixed a light cylinder on which a cocoon fibre is wound up as the deflection starts from zero. The cocoon fibre, which only gets into action at the middle of the swing, opens a light contact which controls the action to be measured. The cocoon fibre may be avoided by attaching a disc very near the top of the torsion wire. A projection on the disc moves between two contacts which are very close together, and can be adjusted so as to establish or break contact at any desired phase of the throw. The apparatus is specially adapted to the study of eddy currents, or of damping in any shape.

NEW TELEPHONE APPARATUS

THE International Electric Co., of 55 Red Cross Street, Barbican (works, 115 Salusbury Road, Kilburn), have brought out a new catalogue of their telephone apparatus. A new type of instrument which they are putting on the market is an inter-communication set with "auto-release," in which the button,

FIG. 1.—FIVE LINE "AUTO-RELEASE." INTERCOMMUNICATION SET.

pressed to connect up any station, also serves to send a ringing current. Fig. 1 shows the internal appearance of a five-station set. Pressing in the button for the wanted stations corresponds with an upward motion of the button. When this is pressed

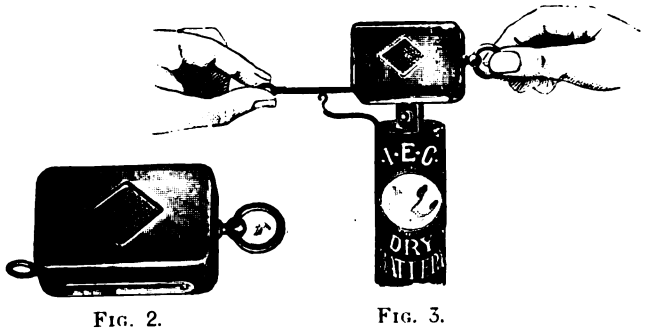

FIG. 2. FIG. 3.

POCKET TESTING INSTRUMENT FOR CELLS OR CONTINUITY.

home, it makes contact with horizontal bars above it which are connected to the battery circuit, and on being released, it catches on a lower bar, which makes contact with the telephone circuit, and keeps the button down until the telephone is hung

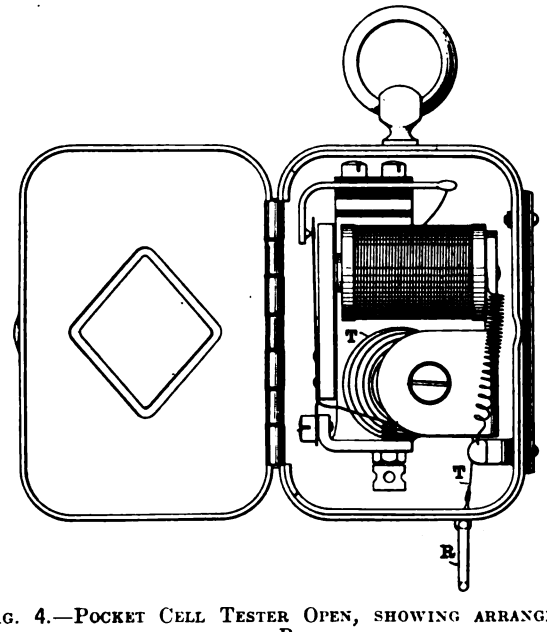

FIG. 4.—POCKET CELL TESTER OPEN, SHOWING ARRANGEMENT OF BUZZER.

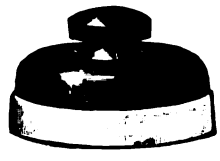
on the hook again. On the telephone being replaced on the hook, this bar is rocked in the usual way, and releases the button so that the connections are restored in order to receive the next incoming call.

Figs. 2, 3, and 4 show an interesting little cell tester, which is a very useful and also a cheap device. As seen by Fig. 2, it is in the form of a match box, at the bottom of which the ring *R* of a metallic spring tape *TT* projects. To test the cell, the tape is pulled out slightly and held against one terminal, while an insulated metal plate at the side of the box is rested on the other terminal as shown in Fig. 3. A small buzzer inside the box is actuated if the cell is in order. As seen in Fig. 4, which is drawn to scale, the whole arrangement is extremely neat.

A NEW BRANCH SWITCH

THE accompanying illustration represents a new branch switch which has been introduced recently by Simplex Conduits, Ltd. The switch is of the turn pattern with quick break, and will recommend itself not only on account of its neat appearance and low projection, but also because of its quick independent action. Inside the cover is a specially shaped fibre disc which is actuated by the milled knob on the outside. This fibre disc is arranged to work the spring in the base of the switch. The centre piece which holds the spring revolves and puts the spring in tension; the latter, however, has no effect until it has passed the centre, when it comes into action immediately, giving a rapid make and break. The cover is not fixed by screwing on, but by two springs fitting into special notches in the porcelain base; to remove the cover, a small screw-driver should be inserted between base and cover opposite either rivet head, or a special key is supplied.



NEW SIMPLEX SWITCH, ½ FULL SIZE.

CATALOGUES AND PAMPHLETS RECEIVED

INCANDESCENT LAMPS.—The Stearn Electric Lamp Co. have issued for the use of dealers and contractors stocking their lamps a booklet and calendar entitled "Useful Hints to Electric Light Users," containing some particulars of tests of Stearn British-made incandescent lamps, and some general notes on the arrangement of lamps for the best economy in house lighting. The firm have also produced an attractive show card calling attention to their lamps.

IGNITION BATTERIES.—A leaflet is to hand from the Hart Accumulator Co., of Stratford, giving prices and particulars of a number of types of ignition battery for motor-cars, motor boats, and motor cycles. These cells are of a type specially designed for the purpose, and vary in capacity from 4 to 200 ampere hours. They are contained in strong celluloid boxes, with sealed lids, vent plugs, and non-corrosive terminals. The large sizes are usually supplied in sets in teak crates, and all can be supplied at an extra price, if desired, in metal cases.

DRAWING OFFICE MATERIALS.—A pamphlet from A. E. Mallandain, of 51 Cheapside, contains a sample of a special tracing paper, and particulars of a neat form of pocket slide rule. Prices are given for executing photo copies of tracings.

ELECTROPLATING AND ELECTROTYPING.—A leaflet from the Langbein-Pfanhauser Works, Ltd., Birmingham, calls attention to plant and materials for electrotyping and electroplating, including motor generators, polishing motors, and all accessories required for nickel, brass, zinc, gold, silver, and copper deposition.

OVERHEAD TRAVELLING CRANES.—Messrs. Vaughan & Son, of Manchester, are issuing a very handsome catalogue giving particulars of a variety of types of travelling cranes, including multimotor electric travelling cranes, light load electric travelling cranes, platform hand power travelling cranes, self-sustaining hand-power travelling cranes, pulley block and trolley travelling cranes, &c. A large number of excellent illustrations are given, and some useful notes are included on the choice of speeds for electric travelling cranes, position of control and electric power generally as applied to cranes.

ELECTRIC LIFTS AND HOISTS.—An attractive pamphlet from Messrs. W. Wadsworth & Sons, of School Hill, Bolton, describes several types of their electric passenger and goods lifts. The gear is of the usual worm and wheel type, but either drum or sheave drive can be had. There are three methods of control from which to choose, namely, hand rope, car-switch, or push-button control. Illustrations of the control and driving gear, and also of various designs for cars, both plain and ornamental, are given. Various systems for operating and controlling small electric dinner and service lifts are also described. Another pamphlet from the same firm deals with electric lifts suitable for use in hotels, offices, warehouses, and particularly those for heavy goods work. Both direct and belt-driven lifts are illustrated from photographs of lifts actually installed under various conditions. The "Wadsworth" type of self-landing and delivering hoist is also fully described, and a large number of illustrations show its application to various sorts of work.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published July 16th, 1908

A full list of these was published in our last issue. The following are abstracts of the more important specifications.

Names in brackets indicate communicators of inventions from abroad.

1907 Patents

6,528. **Multiple-unit Control.** BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). A system of multiple-unit control in which each of the motor-cars of the train is provided with a motor controller, the motor controllers in turn being operated by means of relays in an independent control circuit consisting of two wires running the length of the train and batteries on the cars. The master controller has two forward and two backward positions. In the backward positions the polarity of the control circuit is reversed. On the first position of the master controller the motors are connected to the supply in series; on the second position the motor controller progressively cuts out the starting resistance and then connects the motors in parallel. This progressive action can be arrested at any desired point by moving the controller back to the first position. Four claims, three figures.

15,335. **Alternating-current Load Equalising Arrangement.** J. S. PECK. This consists of two single-phase commutator motors mounted with a flywheel upon a common shaft. The armature winding of one motor and the field winding of the other motor are supplied from one phase, and the field winding of the one motor and the armature of the other motor are supplied from the second phase, of a two-phase supply obtained by means of a motor generator, or by phase transformation, from the supply circuit. The equalising action is obtained by automatically varying the field strengths of the motor. Four claims, three figures.

23,708. **Control of Single-phase Commutator Motors.** BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). The torque and current of an alternating-current series motor fall off less rapidly with increase of speed than in a direct-current motor, so that an alternating-current motor designed for the same starting torque as a direct-current motor tends to overload itself at high speeds. According to the present invention such motors are so connected that the shunt excitation is automatically increased as the speed increases, thereby reducing the speed for a given current. On a locomotive, with two such motors, this effect is obtained by producing a phase displacement between the voltages at the armature terminals of the two motors, and impressing on the fields a shunt voltage corresponding in amount to this phase displacement. This phase-displacement increases with increase of speed, so that the shunt excitation will automatically increase with the speed. The shunt voltage is nearly 90° out of phase with the motor terminal voltage, and consequently the shunt field current is nearly in phase with the motor terminal voltage. Six claims, three figures.

1908 Patents

3,986. **Electrically-driven Rolling Mills.** ALLGEMEINE ELEKTRICITÄTS GESELLSCHAFT. It is often necessary to operate motors driving rolling mills at a somewhat reduced speed. When three-phase induction motors are used, the reduced speed is obtained by inserting resistance in the rotor. The speed of such motors varies with the load, and it is usual to automatically regulate the resistance in the rotor circuit by means of a centrifugal governor mounted on the shaft of the motor. According to this invention, the governor is geared to the motor by a variable ratio gear, so that, although the motor may be running at a reduced speed, the governor may be caused to rotate at its original speed, and so have the same regulating effect at reduced speeds of the motor as at the normal speed. Two claims, one figure.

6,587. **Microphone Transmitter.** C. E. EGNÉR and J. G. HOLMSTRÖM. In microphones consisting of particles of carbon bearing freely against each other, the variations in current strength are caused by the varying resistance of the air films between the particles. According to the present invention, the microphone chamber is hermetically sealed, and is filled with an active gas, such as hydrogen or any hydrocarbon gas, at a pressure approximately equal to that of the atmosphere. The amplitude of the current oscillations are said to be greatly increased by this means. One claim, no figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.

Summaries of the more important of these patents will appear in our next issue.

1907 Patents

12,220 JOHNSON (*Badische Anilin & Soda Fabrik*). Production of currents of high periodicity.

12,260. RHODE. Combined electric and gas lamps.

14,649, WYDTS & JEUDI. Electric battery.

14,713, HATFIELD & LEWIS. Arc lamps.

14,745, FESSENDEN. Method of storing energy.

14,831, THORPE. Electric prepayment meters.

15,100A, STRAY. Electric secondary clocks.

15,234, DAWSON & BUCKHAM. Electric signalling.

15,262, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Controlling mechanism.

15,311, WEGUELIN. Automatic circuit closers.

15,363, GESE. Electrically-driven pulley blocks.

15,365, KITCHEN & VON BERNUTH. Power-generating systems.

15,510, DEUTSCHE GASGLUHLICHT AKT.-GES. Manufacture of lamp filaments.

15,922, POLLITT. Electric winches.

19,010, WALKER. Brushes and brush-rockers.

20,061, STELJES. Electrical pendulum.

20,639, CLAREMONT. Filling cable joint boxes.

21,646, COOK & SOKAL. Storage batteries.

22,204, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Valves.

23,980, HALLOWELL. Brakes for tramcars.

24,138, JONES. Electric arc lamps.

24,707, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Refractory conductors.

25,987, FELTEN & GUILLEAUME-LAHMEYERWERKE AKT.-GES. Brake-operating mechanism of electric lifts.

26,642. CREIGHTON. Protection of electrical systems.

26,754. BAILEY, HOLT, & DITTMAR. Valves.

27,105. WILKINS. Standardisation of service meters.

27,809, MARKS (*Parker-Clark Electric Co.*). Incandescent electric lamps.

27,989, WOLTMANN. Electric railway installations.

1908 Patents

1,913, THOMPSON. Train controlling mechanism for automatically applying the brakes.

2,354, BONNER & BONNER. Railway rail joints.

2,375, HOWARD. Alternating current relays.

5,279, ALI-COHEN. Insulating, impregnating, and protective compositions.

7,045, NOEGGERATH. Homopolar machines.

8,646, KOCH. Ignition of miners' safety lamps.

8,888, SCHMIDT. Valves.

9,760, SCHUBERT. Lighting devices for street gas lamps.

12,908, EYQUEM. Sparking plug for explosion engines.

Complete Specifications open to Public Inspection before Acceptance.

1908 Patents

9,636, SIEMENS-SCHUCKERTWERKE-GES. Fittings for glow lamps.

13,092, AKT-GES. BROWN, BOVERI, ET CIE. Transformers.

13,734, CORNARO. Electrodes for electric furnaces, radiators, or lamps.

13,741, SCHERL. Single track vehicles.

13,865, FESSENDEN. Electric signalling.

Application for Amendment

Further particulars and instructions as to procedure in opposition to amendment will be found in the Official Journal of the Patent Office of July 15th, 1908.

16,269 of 1906, **Electric Induction Furnace.** THE GRÖNDAL KJELLIN CO., LTD., and J. HÄRDÉN seek leave to amend the specification numbered as above, for "Improvements Relating to Electric Induction Furnaces," on account of the doubtful validity of the first claim. The amendment consists in striking out this claim, and making a slight alteration in the text of the specification.

Expiring Patents

The following patents expire during the current week after a life of fourteen years :—

14,246 of July 24th, 1894, **Three-phase to Two-phase Transformation.** C. F. SCOTT. The well-known method of transforming three-phase alternating current to two-phase, or *vice-versa*, by connecting the two phases of the two-phase system to the primary windings of two transformers. One secondary winding is connected to approximately the middle point of the other secondary winding, and the remaining three terminals are connected to the three-phase line.

14,602 of July 30th, 1894, **Controller for Electric Motors.** J. B. CANET and A. HILLAIRET. A controller for motors operating lifts, winches, and other apparatus with limited travel or movement. Different running speeds are provided for, and a magnetic clutch within the controller case releases the handle, breaks circuit, and short-circuits the motor when the lift or other apparatus reaches the limit of travel.

NEW COMPANIES

BAUXITE REFINING CO.—This company was registered on June 27th, with a capital of £100,000 in £1 shares, to carry on the business of manufacturers of and dealers in alumina or other materials or ingredients used in the production of aluminium, owners of mines and minerals, winners and workers of mineral substances, &c. The subscribers are C. J. Lunn, W. Moir, G. C. Pullman, A. G. Ratcliff, H. Barnes, W. Graham, and W. Newbert. No initial public issue. The number of directors is not to be less than two nor more than five; the first are Hon. Sir James Sivewright, K.C.M.G., J. E. Davidson, and R. S. Portheim. So long as the United Alkali Co., Ltd., or their nominees hold 1,000 shares, they may appoint a director. Qualification (except such director), £100. Remuneration while only three directors, £500 per annum, divided; when more than three, proportionate increase. Registered office: Pandon Building, Newcastle-on-Tyne.

BROWN-MACKENZIE SIGNAL CO.—This company was registered in Dublin on July 3rd, with a capital of £1,000 in £1 shares, to acquire certain British patents for improvements in electric signalling on railways, and also any patent granted in any other country with respect to the same invention. The subscribers are G. H. Brown, W. J. Mackenzie, W. R. McMurray, and H. Brown, jun. Private company. The first directors are G. H. Brown, W. R. McMurray, and H. Brown, jun. Registered office: 1 Marcus Ward Street, Belfast.

CHISHOLM, GRAY & CO.—This company was registered on June 23rd, with a capital of £7,000 in £1 shares, to acquire the business carried on in Birmingham as the "Chisholm Manufacturing Co.," to acquire the patents granted to A. Cripwell for improvements in electric switches, portiere rods, plugs for sink wastes and sanitary socket connections, to adopt agreements (1) with the said A. Cripwell, and (2) with D. Whamond and the said A. Cripwell, and to carry on the business of brassfounders, electricians, manufacturers of electrical accessories, appliances, and machinery, &c. The subscribers are:—G. Chisholm, R. Gray, D. Whamond, D. Clarke, E. G. Chisholm, T. Gardiner, E. S. MacLaren. No initial public issue. The number of directors is not to be less than two nor more than four; the first are G. Chisholm (managing director) and R. Gray. Qualification 1 share. Remuneration of G. S. Chisholm not less than £250 per annum, with an increase of £25 per annum for four years; of other directors as fixed by the company. Registered office, Providence Works, Fleet Street, Birmingham.

CHIPPING NORTON & DISTRICT ELECTRIC LIGHT & POWER CO.—This company was registered on June 29th, with a capital of £10,000 in £5 shares (1,000 preference), to acquire the undertaking and assets of the Chipping Norton Electric Light & Power Co., Ltd., and to carry on the business of an electric light and power company in all its branches. The subscribers are C. A. Bernard, L. Gatrall, F. J. Cole, F. Boulding, J. R. Smith, C. F. Butcher, and W. B. Murray Thomson. Minimum cash subscription 10 per cent. of the shares offered to the public. The number of directors is not to be less than two nor more than five; the subscribers are to appoint the first. Qualification, 10 shares. Remuneration as fixed by the company. Registered office: The Power Station, Chipping Norton, Oxon.

A. C. COSSOR.—This company was registered on July 2nd, with a capital of £3,500 in £1 shares, to take over the business of a scientific and electrical instrument maker, manufacturer of incandescent electric lamps, electrical apparatus, vacuum tubes, mercury pumps, McLeod gauges, X-ray tubes and apparatus, and electro-medical apparatus, experimental and electrical glass-blower, &c., carried on by A. C. Cossor at 54 Farringdon Road, E.C. Private company, with only two subscribers, viz., A. C. Cossor, Fawley Cottage, Fawley, Hants, scientific instrument maker, and W. R. Bullimore, 16 Linthorpe Road, Stamford Hill, N., electrical engineer, each taking one share. The number of directors is not to be less than two nor more than three; the first are A. C. Cossor (chairman), W. R. Bullimore (managing director), and Mrs. A. Cossor. Remuneration, £141 per annum, divisible. Registered office: 54 Farringdon Road, E.C.

DODD & OULTON.—This company was registered on June 23rd, with a capital of £20,000 in £5 shares (1,000 preference), to acquire the business carried on in Liverpool, Manchester, and elsewhere, as "Dodd & Oulton," to adopt an agreement with G. Oulton and W. F. B. Oulton, and to carry on the business of brassfounders, manufacturers of, and dealers in, gas and electric light fittings, silicate paints and sanitary appliances, electrical engineers, &c. The subscribers are:—G. Oulton, W. F. B. Oulton, Mrs. K. C. Dodd, Miss Annie Dodd, Miss Ada Dodd, A. N. Oulton, J. B. Kidwell. No initial public issue. The number of directors is not to be less than three nor more than seven; the first are G. Oulton, W. F. B. Oulton, A. N. Oulton, and J. B. Kidwell. The trustees of the late T. Dodd may, while holding 50 ordinary shares, appoint a director in the place of J. B. Kidwell. Qualification (except first directors), £250. Remuneration of G. Oulton, £520 per annum; of W. F. B. Oulton, £400 per annum; of A. N. Oulton and J. B. Kidwell as fixed by company. Table "A" mainly applies. The total amount secured by debentures outstanding shall not, without the consent of the holders of three-quarters of the preference shares, exceed £5,000.

ELECTRIC TAXICAB CO.—This company was registered on July 3rd, with a capital of £300,000 in £1 shares, to carry on in London and elsewhere the business of proprietors of motor-cabs, cars, carriages, and vehicles (particularly electric cabs), garage proprietors, electricians, electrical engineers, &c. The subscribers are Rt. Hon. Lord Westbury, Sir David Lionel Goldsmid-Stern-Salomons, Bt., Sir Bache Cunard, H. Willmott, W. M. Rolph, C. L. Samson, T. G. Chambers, W. C. West, E. N. Ruddock. Minimum cash subscription, 60,000 shares. The first directors are Rt. Hon. Lord Westbury, Sir David S. Goldsmid-Stern-Salomons, Bt., Sir Bache, Cunard, Bt., H. Willmott, W. M. Rolph, C. L. Samson, and T. G. Chambers. Qualification, 200 shares. Remuneration (except managing director), £250 each per annum (chairman, £500). Registered office, Dashwood House, New Broad Street, E.C.

ERNEST SCOTT & CO.—This company was registered on July 3rd, with a capital of £30,000 in £1 shares, to acquire the business carried on by E. Scott at London, Manchester, and Glasgow, as "Ernest Style & Co.," and to carry on the business of mechanical and electrical engineers, machinery manufacturers, &c. Private company, with only two subscribers, viz., E. Scott, 8 Frognal, Hampstead, N.W., Engineer; and H. J. Pooley, 65 Elm Park Road, Finchley, N., Engineer, each taking one share. The number of directors is not to be less than 3, nor more than 7; the first are E. Scott (Chairman and Managing Director), and others to be appointed by him. Qualification, £200. Remuneration of E. Scott, £1,000 per annum. Registered by Hillearys, 5 Fenchurch Buildings, E.C.

J. P. HALL & CO., LTD.—This company was registered on June 27th, with a capital of £35,000 in £1 shares, to carry on the business of electrical and mechanical engineers and machinists, manufacturers of electrical and other apparatus and appliances, boiler and economiser makers, motor-car manufacturers, carriers of passengers and goods, &c. The subscribers are J. P. Hall, A. G. Hall, Mrs. H. L. G. Duncuft, J. Duncuft, Mrs. M. A. Hall, E. Trustram, and A. E. Marland. No initial public issue. The number of directors is not to be less than two nor more than six; the first are J. P. Hall and A. G. Hall (both permanent); special qualification, £500 shares. Qualification of ordinary directors, £200. Remuneration, £300 each per annum. Registered by Waterlow Bros. & Layton, Ltd., Birchin Lane, E.C.

HYDRO-ELECTRICAL GEAR CO.—This company was registered on June 30th, with a capital of £6,000 in 5,000 participating cumulative preference shares of £1 each, and 20,000 deferred ordinary shares of 1s. each, to adopt an agreement with Col. Boddam, and to carry on the business of lift manufacturers, engineers, builders of machinery and electrical apparatus, &c. The subscribers are Col. E. T. Boddam, H. R. Reynolds, W. P. Hewett, R. P. Hornby, C. R. Cooledge, F. N. Reckitt, and A. E. Goddard. No initial public issue. The first directors are Viscount Molesworth, C. E. Peczenik, and R. P. Hornby. Qualification (except first directors), 100 shares. Remuneration, £125 each per annum (£25 extra for the chairman). Registered office: 11 Pancras Lane, E.C.

MALTA TRAMWAYS.—This company was registered on July 9th, with a capital of £140,000 in £1 shares, to acquire the tramway undertaking and passenger lift carried on in Malta by Macartney, McElroy & Co., Ltd., to construct and equip tramways, railways, lifts, waterways, and other means of communication and transit in Malta and elsewhere, and to carry on the business of carriers of passengers and goods, railway, tramway, and lift proprietors, generators, accumulators, and distributors of electricity, &c. The subscribers are J. F. Macartney, J. A. McElroy, Major O. Lovell-Wright, F. A. Scadding, H. C. Holt, E. A. Nuttall, and F. A. Mitchener. Minimum cash subscription, 100 shares. The number of directors is not to be less than two nor more than nine; the first are J. F. Macartney, J. A. McElroy, and F. H. Carter. Qualification, £200. Remuneration, £300 per annum, divisible. Registered office:—Caxton House, Westminster, S.W.

NORFOLK ELECTRICAL CO.—This company was registered on July 6th, with a capital of £2,000 in £1 shares, to acquire the business carried on in Birmingham as the Norfolk Electrical Co., and to carry on the business of dealers in electrical goods and appliances connected with the application of electricity for lighting, heating, motive power or otherwise, &c. Private company, with two subscribers, viz., G. W. Holt, Norfolk House, Cannon Street, Birmingham, merchant, and J. A. Dale, 12 Bennett's Hill, Birmingham, solicitor, each taking one share. The number of directors is not to be less than two nor more than five; the subscribers are to appoint the first. Remuneration as fixed by the company. Registered office: Norfolk House, Cannon Street, Birmingham.

RAILLESS ELECTRIC TRACTION CO.—This company was registered on July 7th, with a capital of £5,000 in 4,750 shares of £1 each and 5,000 shares of 1s. each, to adopt an agreement with M. Schiemann and F. Momber, and to carry on the business of engineers, electricians, suppliers of electricity for light, heat, motive power or otherwise, manufacturers of and dealers in electrical apparatus, &c. Private company, with only two subscribers, viz., F. D. Fox, 56 Moorgate Street, E.C.,

C.E., and T. G. Gribble, 8 Dagmar Road, Stroud Green, N., C.E., each taking one ordinary share. The number of directors is not to be less than three nor more than seven; the first are T. G. Gribble, H. O. Foster, F. D. Fox, and B. D. Fox. Remuneration, £150 each per annum (chairman, £300).

METROPOLITAN ELECTRIC TRAMWAYS BILL

The Commissioner of Police and London Tramways

AN unusually interesting discussion took place before the Unopposed Committee of the House of Commons on Thursday in connection with a report by the Home Office, in conjunction with the Commissioner of Police, upon the Metropolitan Electric Tramways Bill. The primary object of the Bill, which has been passed by the House of Lords, is the construction of a short extension of the Harrow Road and Paddington tramways. The extension in question is within the County of London, and the County Council has given its consent to the Bill on the understanding that the new line shall not be constructed without its permission, and that if the Council itself should decide to promote a line along the same route instead of the company, the latter shall not oppose. All this has been agreed between the parties.

The contentious portion of the Bill arose upon the consideration, as mentioned above, of a report by the Home Office and the Commissioner of Police, which dealt with certain important matters affecting tramway authorities, as it is the intention of the Home Office to ask for similar powers in relation to all tramway bills promoted in the future in the area of the Metropolitan Police. It may be stated that in resisting the proposals of the Commissioner of Police—as the Home Office really made its report on his behalf—the Metropolitan Electric Tramways, Ltd., had the support of the London County Council.

The first point raised was that in the clause of the Bill authorising the company to lay down temporary rails either for purposes of reconstruction or repairs, it should be specified that such rails must be on a level with the roadway. This, the promoters contended, would be quite impracticable, and would mean the laying of a permanent tramway for temporary work. Evidence was given on behalf of the Commissioner of Police to the effect that this request was made on account of the large number of accidents which have occurred during the reconstruction of the London County Council tramways, when temporary rails laid on the surface of the roadway were largely made use of. An instance was mentioned of an omnibus which was overturned and thrown into the trench dug for the conduit, and of a van which met with a similar fate, whilst, it was said, there were records of hundreds of accidents directly attributable to the raised rails used during the reconstruction of the tramways in London. The Chairman, after consultations, announced that the Committee did not think the suggestion a practicable one.

Another point raised was as to calling the attention of the Board of Trade to the condition of tramway tracks, it being asked that the Commissioner of Police should have authority to do so, and to set the Board of Trade in motion. The present position is that the road authority or twenty ratepayers may do this—it is very seldom done—but that when, hitherto, the Commissioner of Police, as responsible for the regulation and safety of the traffic, has gone to the Board of Trade on the question of the condition of a particular section of track, it has been pointed out to him that he has no statutory powers to do so, and that the Board of Trade cannot act upon his information. At the same time, the Board of Trade concurred in the suggestion now made. Mr. Whittaker Thompson, the Chairman of the Highways Committee of the London County Council, gave evidence against the proposal, contending that it created another authority to keep a watch over the tramways. The Commissioner of Police at present, he pointed out, could summon the tramway authority in a court of summary jurisdiction, and this fact, coupled with the right of the road authority or 20 ratepayers, to go to the Board of Trade, was, in the opinion of the London County Council, sufficient protection for the ordinary traffic. In many cases the cause of the tramway rails projecting above the surface of the ordinary level of the road was due to the road authority not having kept their portion of the roadway in a proper state of repair. The Committee, however, by a majority, decided in favour of the Commissioner of Police.

The next point was with regard to parcel carrying upon the tramways proposed in the Bill, which the Commissioner of Police objected to. It was pointed out for the promoters that they already had powers to carry parcels over the whole of the remainder of their system—although, as a matter of fact, they had never been put into force—and that similar powers had been granted in numerous cases, and were in operation in many towns. In fact, they were in operation upon the system of the South Metropolitan Electric Tramways & Lighting Co. within the area of the Metropolitan Police, and no complaint had been received. The view of the Commissioner of Police upon this point was that there was a possibility of dividing the attention of the driver—at whose end of the car the parcels were to be placed—between looking after these and driving the car, that such parcels would impede him in his driving duties, and, further, they might block up the doors of the car at the driving end, and prevent their use by the passengers in case, say, of fire. During the discussion reference was made to the carrying of parcels upon the system of the Dublin United Tramways Co., the Potteries Electric Traction Co., and the Manchester Corporation without any complaint. Eventually, the Committee, by a majority, allowed the company the clause in question.

The final point raised by the report of the Home Office and the Commissioner of Police was a request to be allowed the use of the tramway standards for affixing direction notices for traffic, &c., in the same way that lamp standards are now used. The company was willing to agree to this in so far as it related to standards used by the public authority for street lighting, but beyond this the promoters objected to being interfered with. A suggested clause put in by the Home Office was of a very wide character, and might have allowed the use of the standards for all manner of purposes, and to this the Committee objected, although favourable to the principle of the suggestion. Mr. James Devonshire, the Managing Director of the Company, stated that he was not opposed to the principle, but wished for some protection as to the manner of carrying it out. The Chairman thereupon announced that, looking to the fact that the Bill only related to a mile of tramway, and that the question had been raised by the Home Office at a very late period of the session, they did not think it necessary to go into the question on this occasion. There had been a strong expression of opinion on the Committee that the Commissioner of Police should have the powers suggested, and the matter should be discussed on another occasion when there was more time for considering the wording of the clause. The proposal, therefore, was agreed to, subject to that observation.

We may point out that the reason for the somewhat belated proposals of the Commissioner of Police, so far as this session is concerned, is that he has recently been asked to consider what further precautions are necessary in the interests of London traffic generally. It is the intention to ask that the points conceded on this Bill shall also be conceded in connection with every future tramway Bill affecting the Metropolitan Police area.

LONDON UNITED TRAMWAYS BILL

Tramways Over Kew Bridge

THIS Bill was considered by a House of Lords Committee, presided over by Lord Donoughmore, on Tuesday. The Bill proposes to confer powers upon the London United Tramways, Ltd., for constructing tramways and widening and altering streets and roads and for other purposes, but, as when the Bill was before the House of Commons, only one part of the Bill was opposed, namely, the proposed tramway, three furlongs in length, over Kew Bridge. As a result of the proceedings in the House of Commons, it was decided that the company should pay £500 per annum each to the Middlesex and Surrey County Councils for the use of the bridge. Since then the two County Councils in question have proposed a clause giving them a veto as to the system of traction which should be adopted upon the bridge, but counsel for them was quite frank in stating that they preferred the conduit system, or, any rate, were opposed to the overhead system. The argument of the company against this was that it would be physically impossible to construct an underground conduit system upon the bridge; but this was met by the evidence, on behalf of the County Councils, of Mr. C. A. Brereton, who designed the bridge, and who expressed the opinion that a conduit tramway could quite well be constructed upon it. Another factor in the question, the company said, was the Richmond Corporation, who, although under the Bill they have a veto as to the system which shall be adopted in their district, *i.e.*, on the Surrey side of the bridge, there was every probability of an agreement being come to for the use of overhead trolley system. Therefore if the Richmond Corporation agreed to the trolley system, it was an unreasonable proposition, Sir Clifton Robinson said, to have the overhead system on both sides of the bridge and the conduit or surface-contact system over the bridge itself, necessitating two breaks. There was no evidence, however, put in as to the Richmond Corporation agreeing, and after deliberation the committee approved of the principle of the County Councils deciding as between the overhead or any other system of traction, but refused to adopt the wording of a suggested amendment, which would have given the County Councils the right to specify which particular system of electric traction should be used. On the consideration of clauses, the committee rejected an amendment by the County Councils compelling the company to submit plans of their proposed work upon the bridge before they were commended, being satisfied that sufficient protection is already given to the County Councils by reason of the fact that the Board of Trade would have to sanction the plans under the general law. With these modifications, the preamble of the Bill was passed.

LOCAL NOTES

ACTON: *Electricity Accounts.*—Mr. S. Lord, accountant to the Urban District Council, has submitted to the Electricity Committee an exhaustive "commercial" report on the accounts of the undertaking for the year ended March 31st. The accountant in his report reviewed the principal differences between the position of a company and that of a local authority owning an electricity undertaking. He remarked that there were many companies which set aside nothing for depreciation. The average amount provided during 1906 for depreciation and reserve per £100 of capital was, in the case of metropolitan companies, £1·45, and of the provincial companies only £0·78, whilst the equivalent sinking fund charge made against local authorities' undertakings was, in the metropolis, £1·82 per cent., and in the provinces £2·76 per cent. Acton Council, for the same year, provided £2·98 per cent. Any deficiency resulting from the year's working must be charged by local authorities upon the current rate, whilst a company would probably accumulate the deficiencies for ultimate discharge out of profits. Upon a "commercial" basis the result of the past year's working showed a gross profit of £1,082, there being left, after the deduction of bad debts, &c., a profit of £1,053. An allowance of £0·78 for depreciation was altogether inadequate, and a fair charge based upon the respective "lives" of the constituent assets would probably be £1,792 (equal to 2·69 per cent.); the result would be a net deficiency of £180. As regards the capital account, the assets undoubtedly stood at less than would be the case if the undertaking had been owned by a company. Further, it was not an uncommon practice for companies to permanently maintain in the balance-sheet the accumulated deficiencies of the first few years' working as "goodwill."

ALDERSHOT: *Electric Lighting Charges.*—The Council has resolved that on and after October 1st next, a flat rate of 3d. per unit shall be charged for energy consumed by arc lamps used for external lighting of business premises, provided that such premises are lighted internally by electric light, and that the consumers provide a separate circuit and pay 2s. per quarter for the hire of the meter to register the special consumption.

AUSTRALIA: *Sydney: New Telephone Switchboard.*—The first section of the new telephone switchboard has been erected in the Sydney Telephone Exchange. This is the first central battery board to be erected in Australia.

Perth: Purchase of Electric Lighting Co.—The City Council have given six months' notice to the Perth Gas Co., of their intention to purchase its electric lighting and gas business.

AYR: *Electricity Accounts.*—There is a debit balance of about £1,000 on the working of the electricity undertaking for the past year, and it has been agreed that £326 at the credit of special reserve revenue account shall be applied towards reducing this deficit. The increase in the coal bill and reduction in the price of lighting are put forward as the reason for this bad result. A special meeting is to be held to consider the question of charges for electricity supply.

BECKENHAM: *London Power Bills.*—A petition is to be presented against the London and District Electric Supply Bill in the House of Commons.

BELGIUM: *National Electricity Supply.*—The *Financial News* states that negotiations have been commenced in certain quarters in Brussels with a view to forming a national electricity company for the purpose of supplying light and power over the whole of Belgium. It is further stated that the Government has approved the general principle of the scheme.

BEXLEY: *Tramway Intercommunication.*—It is anticipated that a working agreement will shortly be arrived at between the District Council and the Erith Council for the through running of the respective tramway systems, the Council having resolved to accept Erith's offer of 6½d. per car mile upon a minimum of 68,000 car miles per annum. It has also been decided to enter into an agreement to lease to the Erith Council the Bexley tramway from a point in Market Place, Bexley Heath, to Northumberland Heath on a yearly tenancy, this being, of course, subject to various conditions.

BIRMINGHAM: *Tramway Extensions.*—Considerable discussion is taking place in the district of Stechford as to whether the Birmingham Corporation should be asked to promote a Bill authorising the construction of tramways in that district, as an extension of the Birmingham system. One section of the residents is urging the District Council to memorialise the Corporation in favour, whilst the other section is opposed to the proposition.

BROUGHTY FERRY: *Electricity Charges.*—The charge for electricity for lighting purposes has been reduced from 6d. to 5½ per unit, and the charge for power has been reduced by one penny per unit.

CHICHESTER: *Electric Lighting Works.*—The Chichester Electric Light & Power Co. have notified the Council of their acquisition of a site on the canal basin for an electric light works.

CHIPPING NORTON: *Electricity Supply.*—The Chipping Norton and District Electric Light & Power Co., Ltd., have given notice of their intention to apply to the Board of Trade for a Provisional Order to supply electrical energy for public and private purposes throughout the borough.

COATBRIDGE: *Tramways.*—The local Tramways Committee has had a conference with a deputation of the Glasgow Town Council with regard to extending the Glasgow Tramways from Bailleston to Langloan, Coatbridge. The local committee is to make overtures to the County Council, and will also memorialise the Glasgow Corporation, asking for the extension of the line in question.

CROMER: *Repayment of Loans.*—Correspondence has taken place between the engineer, Messrs. Edmundson's Electricity Corporation, and the Town Clerk with reference to the decision of the Local Government Board as to the loan for past and prospective expenditure, and an application has been made to the Board to extend the period for repayment of loans to twenty years from the present time.

CROYDON: *Tramway Accounts.*—The annual report of Mr. T. B. Goodyer, the General Manager of the Corporation tramways system, shows a revenue of £74,132, the working expenses amounting to £55,806. Adding bank interest, the gross balance is £19,257. Interest, sinking fund, &c., amounted to £16,428, leaving a balance of £2,829. The reduced net balance in comparison with the previous one is attributed to the decrease in traffic receipts, £1,785; loss on Thornton Heath route, £2,150; increase in current charges, £2,850; increase in permanent way charges, £2,460; and increase in capital charges, £2,000, making a total of £11,245. The amount earned per car mile has been 9·20d., compared with 9·88d., and adding the advertisement rental, the average receipts per car mile amounts to 9·44d. This decrease is due to carrying less passengers at the higher rate of fares, and the low average receipts per car mile, namely, 8·45d. upon the Thornton Heath route, and it is recommended that this route should be discontinued. The number of passengers carried was 16,277,318, an increase of 83,416 over the previous year. The total number of units used for traction, car lighting, and grinding out rail corrugation was 2,247,586, an increase of 428,292 units over the previous year. The consumption and cost per car mile works out at 1·19 units and 2·38d. respectively, with 1·01 and 2·02d. last year. Complaint is made in the report that although close upon 2¼ million units have been consumed, the price still remains at 2d. per unit, and the current costs amount to no less than 30 per cent. of the entire working expenses of the department. It is calculated that the Croydon tramway department pays 42 per cent. more for its energy than the average of all other metropolitan systems. The overhead wire along the main line from Norbury to Purley has been renewed during the year at £1,214. The percentage of expenditure to receipts is 74·45. The department has now 70 cars in stock; the sinking fund stands at £11,927, and the renewals fund at £15,418, whilst £18,100 have been applied in reduction of debt.

DARWEN: *Electricity and Tramways Accounts.*—The Borough Treasurer of Darwen, in his annual report issued on Saturday, mentions a surplus of £104 in the electricity works, and £242 on the Darwen section of the electric tramways. On the Hoddlesden section there was a deficiency of £605. The revenue of the electricity department shows a gross profit of £3,391, the net profit of £104 reducing the adverse balance from £1,370 to £1,266. The number of units sold was 675,527, compared with 660,812 for 1907, an increase of 1·93 per cent. After allowing £900 for depreciation, there was a gross profit of £4,068 on the Darwen section of the tramways and a net profit of £242 10s. 9d., compared with a gross profit of £4,169 and a net profit of £477 for the previous year, a decrease of £235. On the Hoddlesden section, after debiting £150 for depreciation, there was a gross profit of £212, but with interest and sinking-fund charges a net loss was shown of £605. The net loss now standing to the debit of this section is £2,522 14s. 10d., towards which a sum of £1,600 has been transferred from rates during the year, leaving the adverse balance £722.

DUNDEE: *Extension of Supply Area.*—The expenses in connection with obtaining the Provisional Order for making the area of supply co-extensive with the enlarged city boundaries amounted to £239.

Third Party Risks.—The Tramways Committee has decided that the department shall be its own insurers against third party risks, and £1,000 per annum is to be allocated for this purpose.

DUNFERMLINE: *Power Company's Mains Assessment.*—A special meeting is to be held for the purpose of deciding whether the Fife Electric Power Co.'s cables passing through the borough shall be placed upon the assessment roll.

GILLINGHAM: *Water-softening Tests.*—The Council have recorded their appreciation of the good results which have been achieved by the senior shift engineer in connection with some water-softening tests recently carried out by him.

Digitized by Google

HARROGATE: *Excess Expenditure.*—Mr. H. R. Hooper held an inquiry at Harrogate last week respecting an application by the Corporation for sanction to borrow £16,500 in connection with the electricity undertaking. During the course of the proceedings the inspector remarked upon the excess of expenditure over the sanctioned loans, and suggested that the best thing to do was to take the capital expenditure up to the year ended March 25th last and see how they stood, and then the Corporation could deal with the sum required from March 26th, 1908. Mr. G. Wilkinson, Borough Electrical Engineer, agreed that this would be the best way to deal with the matter, as it would make a new starting point, which he himself would appreciate.

HASLINGDEN: *Tramways.*—At the Town Council on Thursday, a letter was read from the Board of Trade approving of the agreement between the Corporations of Haslingden and Accrington for the running of cars between the two boroughs. A further letter from the Board of Trade was read, stating that they could not fix a date for the inspection of the tramways until they are informed that the lines in question and their electrical equipment were complete in all respects.

HASTINGS: *Sunday Trams.*—The Tramways Co. have made an application to the Corporation for consent to run the trams on Sunday. There appears to be no objection to Sunday running, but there is a point of difference between the Company and the Council as to whether, in the event of the purchase of the tramways by the local authority, Sunday profits shall be taken into consideration in fixing the price. The Council at its last meeting decided to agree to Sunday trams on condition that Sunday profits were excluded.

HEREFORD: *Electricity Accounts.*—The report of the Electric Lighting Committee for the year 1907-8 shows a net profit of £219 after meeting interest and sinking fund. The number of units sold was 286,591, compared with 214,621 for the previous year. The income amounted to £4,679 and the expenditure to £3,208. The estimates for the coming year are: income, £4,520; expenditure, including capital charges, £4,421.

ISLE OF THANET: *Electric Lighting.*—The Rural District Council has received a letter from Messrs. Foote & Milne, giving notice of their intention to apply for an electric lighting Provisional Order.

JOHNSTONE: *Electric Lighting.*—In reply to a communication from the Paisley Town Council relating to the supply of electricity in Johnstone, the Council has decided not to take advantage of the offer owing to the heavy capital expenditure involved.

KIRKCALDY: *Tramway Accounts.*—It was reported at the last meeting of the Council that the tramway accounts show a deficit of £580 for the last completed year, and the electric lighting accounts a deficit of £302.

LINTHWAITE: *Condition of Tramway Track.*—The Huddersfield Corporation has complained to the Urban District Council with regard to the bad condition of the tramway track, which the Council is under agreement to maintain. The complaint stated that a large number of cars have had to be withdrawn owing to the damage caused by the bad condition of the track. The Council claim that the cars are defective and not the track, and a reply has been sent to the Huddersfield Tramways Committee that the Council has inspected the rails and that all necessary repairs in its opinion are being carried out.

LIVERPOOL: *First-class Tramcars.*—In spite of the opposition, the proposal of the Tramways Committee to run first-class tramcars was agreed to by the County Council on Thursday.

Libel Action.—Mr. Justice Pickford and a special jury commenced the hearing last week of an action for conspiracy and libel brought by Alderman Smith, Deputy Chairman of the Tramways Committee, against Messrs. Skelton, Stoddart & Yates, all of whom are members of the Liverpool City Council. According to the pleadings, plaintiff claims damages for letters written to the local papers and statements made between October 1st, 1907, and March 10th, 1908, which are alleged to cast reflections upon his conduct as chairman of the Electric Lighting Committee, to which he was appointed in November, 1894, and as a deputy chairman of the Tramways Committee, which position he has held since 1898. On Monday the jury found that the plaintiff had not proved malice, and returned a verdict for the defendants with costs.

LLANDUDNO: *Electricity Charges.*—The accounts of the electricity undertaking show a profit of £1,480. The recommendation by the Electricity Committee to reduce the charges upon the maximum demand system from 7d. and 2½d. to 7d. and 2d. per unit, and the contract rate for consumers taking 1,500 units from 4½d. to 4d. per unit, has been approved.

LONDON: *London County Council: Tramway Employees.*—The London District Council of the Tramway and Vehicle Workers' Association, which represents the whole of the members of the Association who are in the employment of the London County Council tramways department, have passed the following resolution:—"That taking into consideration the unnecessary delay of the London County Council in dealing with the programme for improved conditions of labour placed before them by the tramway employees in May, 1907, the Executive Council be requested to forward an ultimatum to the London County Council that if a satisfactory reply is not received within 21 days, due notice be given (as per rule) that the Executive Council will take a ballot of the members with a view to withholding their labour."

Improvement in Steam Valves.—The General Purposes Committee report that Mr. E. W. Dickinson, superintendent at the Greenwich power station, has designed an improvement adaptable to steam valves which has greatly improved the working of the machinery at the Greenwich power station. The Highways Committee concur with the suggestion of Messrs. Hopkinson & Co., the makers, that the device should be patented, subject to the condition that the Council may use the patent without payment, should they so desire.

Bermondsey: Electricity Accounts.—The estimates for the year ending March 31st, 1909, anticipate a surplus of £1,298. The financial statement for the year 1907-8, which has just been issued, shows that up to March 31st, £145,899 had been borrowed in respect of the undertaking, the amount of loans repaid being £6,812. On the revenue account, the total working expenditure was £10,043, and the total income £19,914. For private lighting £14,395 was received. Public lighting brought in an income of £4,115. There is a net profit, after the payment of interest on mortgage debt and bank overdraft and instalments of principal of money borrowed, amounting to £888, which is to be carried forward. Provision has been made for standing charges (such as interest on mortgage debt, &c.) accrued, but not due for payment until after the close of the year, to the amount of £2,659, and this is treated for the present as a charge on the reserve fund. During the year ended March 31st, current sold totalled 2,672,617 units (public lamps, 569,678 units; private consumers, 2,102,939 units), as compared with the previous year's figures of 1,906,489 units (public lamps, 504,094; private consumers, 1,402,395).

Lewisham: Underground Wires.—At the Clerkenwell Police Court on Friday, the case of the Lewisham Borough Council *v.* the Postmaster-General was heard, the point in dispute being whether certain wires connecting up fire-alarm points in eight streets in Lewisham with fire stations, should be carried on poles or put underground. The Postmaster-General insisted that poles should be made use of on the score of expense, whilst the Lewisham Borough Council argued that the wires should be placed underground from the point of view of the amenities of the district. Sir Robert Hunter, solicitor to the Post Office, stated that a saving of £670 would be effected by the use of poles, the cost by this method being £178 against £800 if the wires were placed underground. The decision of the magistrates was reserved until he has inspected the roads in question.

MAIDENHEAD: *Electricity Accounts.*—There was a loss of £657 upon the Council's electric supply undertaking for the past year.

MANCHESTER: *Sub-station Inspection.*—The Electricity Committee has made a tour of inspection of several of the sub-stations in the city, and at the close of the tour satisfaction was expressed with the condition of the stations and the efficiency of the work carried out.

MANSFIELD: *Electricity Accounts.*—The gross profit upon the electrical undertaking for 1907-8 amounted to £3,979, and, after deducting capital charges, there remains £553. The sum of £500 is to be handed over towards the relief of rates.

MARLBOROUGH: *Electric Lighting.*—The Marlborough Electric Supply Co. have notified the Council of their intention to apply for a Provisional Order to supply electricity for public and private purposes.

NEWPORT: *Tramway Accounts.*—A discussion took place at the last meeting of the Town Council upon the annual report of the Electric and Tramways Committee. Mr. F. Phillips, chairman of the committee, said that, if looked at from the point of view of a company, the undertaking had made a profit of 4 per cent.

PLYMOUTH: *Electricity Accounts.*—The Treasurer's statement in regard to the finances of the electricity undertaking during the past year shows an income of £24,611, whilst the working expenses amounted to £13,147. After deducting interest and sinking fund and transferring £1,300 to the rates, the balance of £833 has been placed to reserve, bringing this fund to £10,053.

PORTLAND (U.S.A.): *Wireless Telegraphy.*—Wireless telegraph stations, under control of the U.S. Navy Department, are now in operation at Cape Blanco, North Head, Columbia River, Tatoosh Island, near Cape Flattery, and at Bremerton naval depôt.

Electric Railways.—According to latest available reports there are 286 miles of electric railway in Oregon, two-thirds of which are in Portland. In Washington there are 330 miles.

RHONDDA: *Tramway Opening.*—The Rhondda Valley Tramways Co. commenced their service on Saturday. Col. Druitt, on behalf of the Board of Trade, inspected the system last week. Arrangements have been made with the Pontypridd Urban District Council for a "Stand-by" supply.

ROSSENDALE: *Tramways Electrification.*—It was reported at the monthly meeting of the Rawtenstall Town Council on

Digitized by Google

Thursday that the Corporation had agreed to pay the Rossendale Valley Steam Tramway Co. £21,750 for their undertaking in the borough of Rawtenstall. Contracts have been let to the extent of £95,000 for the electrification of the system, and the total spent to date on the electricity and tramways undertaking is £115,000. It has been decided to extend the system from Crawshawbooth to Loveclough.

SOUTHPORT: *Electricity Accounts.*—The accounts of the Corporation electricity undertaking for the past year show a net profit of £4,000.

SWINDON: *Extensions.*—With regard to the proposed extensions to the generating plant at an estimated cost of £6,252, the Electricity Committee recommend that this proposal should be deferred until November.

Advertising Electricity.—The sub-committee of the Electricity and Tramways Committee has been instructed to prepare a pamphlet setting forth the advantages of electricity, especially having regard to the economy of metal filament lamps.

WILLESDEN: *Tramway Road Widenings.*—The Urban District Council has received a letter from the Metropolitan Electric Tramways, Ltd., stating that the widenings of Harrow Road would shortly be completed, and suggesting an inspection in order that the bond may be surrendered to the company. The General Purposes Committee, however, are of opinion that the whole of the work should be completed before this is done, and that a further extension of three months be granted the company to enable them to complete.

WOLVERHAMPTON: *Electricity Accounts.*—The accounts of the electricity undertaking for the year ended March 31st, 1908, show a gross profit of £15,122 12s., equal to 7·7 per cent. on the capital expenditure. Capital charges absorb £11,797 5s., leaving a net profit of £3,325 7s. This is somewhat lower than that of last year, for the following reasons:—Additional capital to the extent of £34,334 was expended during the year, the greater portion being in respect of the recent extensions to the main generating station at Commercial Road. These were practically completed early in March last, but no revenue was obtained from the new plant during the period covered by these accounts. The additional interest and sinking fund incurred and the absence of compensating revenue is more than sufficient to account for the reduced profit. The cost per unit still remains at a low figure, although during the past 12 months the cost of repairs and maintenance has been considerably increased. Moreover, in accordance with the dictates of the Local Government Board, the wages of all permanent employees when engaged on capital work have to be charged to revenue account, and all meters and indicators are now purchased out of revenue, owing to the refusal of the Local Government Board to grant a loan for a longer period than five years in respect of these articles. During the year ended March 31st, 1908, the total units generated at the destructor station were 957,329, representing a total revenue of £1,396. The output of electrical energy for private consumers for lighting and motive power purposes increased by 32 per cent., but this rate of progress is being considerably exceeded during the current financial year. The total number of motors connected to the mains on March 31st last was 283, representing an aggregate of 2,135 brake horse power. This is an increase of 586 brake horse power installed during the 12 months ending March 31st, 1908. The total number of units sold was 4,554,457, of which 1,563,776 units were for traction. The maximum load upon the station was 2,450 kw.

WORCESTER: *Powick Generating Station.*—The Electricity Committee has passed a resolution authorising the chairman to sell, at the best prices that can be obtained, the old plant which is to be removed from the Powick generating station. This has been agreed to by the Corporation.

YARMOUTH: *Electricity Accounts.*—The accounts for the year ended March 31st, 1908, show a capital expenditure during the year of £5,156. The total capital account now stands at £97,125, and there is a balance of unexpended loans of £1,019. The working expenditure during the year amounted to £12,442, whilst the income amounted to £19,523. After deducting interest and sinking fund, &c., there is a small deficit of £14. The number of units sold were 1,513,937, of which 213,137 were for public lamps, 655,366 for tramways, 17,235 under contract, and 628,199 for private consumers. There are now 181 public arc lamps and 100 Osram lamps.

ZANZIBAR: *Wireless Telegraphy.*—Wireless telegraphy has been installed between the principal ports of the two islands, a distance of about 68 miles. The system adopted is Lodge-Muirhead, which is found to work successfully, and has proved of great advantage to both the Government and the mercantile community.

Electric Light.—The Electric Light Co. has, during 1907, considerably increased the scope of its activity, and in addition to the Sultan's Palace, Government offices, and the public streets, now lights most of the European and some of the Indian residences. It is gratifying to know that the dynamos and most of the materials employed are of British manufacture.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Miscellaneous

LONDON: *London County Council.*—The Highways Committee recommend that tenders should be invited for the lighting of Westminster Bridge by electricity. The committee state that the bridge is illuminated at present partly by gas and partly by electricity, at a total cost of £512, but that the substitution of arc lamps for the existing gas lamps would reduce the annual cost to £436, whilst adding largely to the general illumination of the bridge.

Battersea.—Electric light services are to be laid at a cost of £50 15s., and the mains are to be extended in Lavender Hill at a cost of £150.

SWINDON.—The Electricity Committee recommend that application be made to the Local Government Board for sanction to borrow £1,800 for extensions to the public arc lighting.

YORK.—Tenders are invited for the following requirements during the two years ending November 30th, 1910:—Carbon brushes, arc lamp carbons, ampere-hour meters, motors, motor starters, incandescent lamps, electrical accessories for wiring department. Particulars from the City Electrical Engineer, and tenders by July 27th.

Generating Stations, Sub-stations, Mains, &c.

CHESTER.—Mr. H. R. Hooper held a Local Government Board inquiry last week into the application by the Council for sanction to borrow £30,500 for electrical extensions. The amount is made up as follows:—Buildings, £3,000; generating sets, £20,700; mains services and public lamps, £4,300; meters, £1,500. A further application is being made for £1,500 for wiring. There was no opposition.

DEWSBURY.—Tenders are invited for a storage battery reversible booster and switch gear and tramway cables. Particulars from the Borough Electrical Engineer, fee, £1 1s. returnable, and tenders to the Chairman of the Electricity Committee by August 3rd (see advertisement this week).

HULL.—Tenders are invited for a 900-kw. direct-current generator (500-550 volts) with Belliss high-speed engine. Firms tendering must have made generators of equal or larger size for coupling to high-speed engines for traction purposes. Particulars from City Engineer (fee £1 1s., returnable), and tenders to the Chairman of the Tramways Committee, Town Clerk's office, by Monday, July 27th.

ILFORD.—The Local Government Board's sanction has been received to the borrowing of £27,000 for extensions to the electricity undertaking.

LONDON: *Islington.*—Mains are to be extended at a cost of £60 to supply current for power to Messrs. Sutton, Sons & Co., Brandon Road.

NEW ZEALAND.—The electrical engineer to the Lyttleton Council recommends that the present system of electric supply shall be changed over to the three-wire system of distribution. He also suggests additions to the plant, involving an expenditure of £15,500. The Council has approved of the proposal, and a loan of £17,000 is to be raised.

RUGBY.—Application is to be made to the Local Government Board for sanction to borrow £1,500 for the provision of an additional 150-kw. generating set.

TAUNTON.—The Local Government Board has sanctioned a loan of £1,670.

WOLVERHAMPTON.—A recommendation of the Electricity Committee that the Tettenhall Road and adjoining area should be lighted electrically at an estimated cost of £740, has been adopted.

Wiring

LONDON.

E.C.—Alterations, &c., to premises in Bridewell Place. Builders, Read & Wilkinson, 20 High Street, Wandsworth.

Extensions to premises in Bread Street, for William & Son, trimming manufacturers. Builders, Hall, Beddall & Co., Pitfield Wharf, Waterloo Bridge, S.E.

N.—Extensions to police station at Islington; approximate cost, £4,400. J. Dixon Butler, surveyor to Metropolitan Police, New Scotland Yard, S.W.

Buildings at Spring Hill, Hackney. Architect, J. Hamilton, 23 Wormwood Street, E.C.

N.W.—Addition to St. Luke's Church, Kilburn. Architect, J. T. Lee, 26 Gt. James' Street, W.

S.E.—Extensions to "The Standard" public-house, 88 High Street, Woolwich. Architects, Gardiner & Theobald, 110 Great Russell Street, W.C.

Working class dwellings by Camberwell Borough Council in Pitman Street. Mr. Oxtoby, Borough Surveyor, Town Hall, Peckham Road, S.E.

Digitized by Google

S.W.—Storehouse for Metropolitan Water Board at Battersea (£4,000). Wm. B. Bryan, Chief Engineer.

Eleven houses, Wimbledon Park Road, Wandsworth. Architect, W. C. Poole, 62 Belleville Road, Wandsworth Common, S.W.

Architect has prepared plans for a bottling store in Britten Street, Chelsea, for Whitbread & Co. A. Dixon, 16 Holland Villas Road, Kensington.

New street in Church Street, Chelsea. Architects, Elms & Jupp, 25 Sackville Street, W.

New divisional offices for the L.C.C. Education Department at St. John's Hill, Wandsworth (£4,340). Builder, H. L. Holloway, Church Street, S.E.

Twenty houses at Clapham Common, West Side, and seventeen houses in Bowood Road, Battersea. Builder, W. H. George, 10 Broomwood Gardens, West Side, Clapham Common, S.W.

Nineteen houses in Canford Road, and four houses at Clapham Common, West Side, S.W. Builder, S. Rashleigh, 23 Tregothnan Road, Stockwell, S.W.

W.—Dickens & Jones, Ltd., silk mercers, 230-244 Regent Street, W., are to extend their premises to 226 and 228.

Marylebone Borough Council are to erect depôt buildings in Grove Road. J. P. Waddington, Borough Surveyor.

Alterations and additions at the Baptist Church, Castle Street, Oxford Street. Architect, T. Jay Evans, 61 Munster Road, Fulham, S.W.

Extension works to St. Peter's Church, Cranley Gardens, Kensington. Builders, Collins & Godfrey, The Cross, Tewkesbury, Glos.

No. 46 Oxford Street, W., is about to be converted into a depôt for the Aerated Bread Co., Ltd., 24 Eastcheap, E.C.

Improvements at the Cavalry Club Buildings, 125, 126, and 127 Piccadilly, W. Architects, Mewes & Davies, 6 Dean Street, Soho, W.

Buildings are to be erected in Ecclaston Place, St. George, Hanover Square, W. Architect, S. F. Monier-Williams, 83A Chester Square, Victoria, S.W.

W.C.—Recreation of Freemasons' Hall and Tavern, Great Queen Street, W.C. Architects, Brown & Barrow, 12 Norfolk Street, Strand, W.C.

PROVINCES.

ABERTRIDWR.—Council school for Glamorgan County Council (£6,000). County architect, D. Pugh-Jones.

BARNES.—Depository in Arundel Terrace. Architect, W. G. Hunt, 17 Vicarage Road, W.

Development of Blind Lane Estate. Architects, Tyers & Jago, 10 John Street, Adelphi, W.C.

BECKENHAM.—New art school by District Council (£1,960); alterations to Technical Institute (£750). Clerk to Council: F. Stevens.

BLACKPOOL.—J. S. Brodie, Borough Engineer and Surveyor, has prepared plans for the erection of a police station.

CHESHUNT.—Herts County Council school at Cheshunt (£4,540). Builders, Clark & Son, Cambridge.

CHICHESTER.—Secondary school for girls (£9,000). Architect, H. P. Roberts, Horsham; builder, F. Privatt, Southsea.

COSHAM (HANTS.).—Disinfecting establishment, mortuary, and quartermasters' quarters at the Alexandra Hospital, War Office.

DARTFORD.—Additional workroom accommodation, Darenth Asylum. W. T. Hatch, Chief Engineer, Metropolitan Asylums Board.

DUDLEY.—Public library in St. James Road. Architect, George H. Wenyon, Owen Street, Tipton; builders, Mark Round & Son, 18 New Street, Dudley.

EAST DEREHAM.—Secondary school (£6,000). F. H. Millington, Chairman of Norfolk Education Committee, T. A. Cox, secretary.

EAST HAM.—Six houses in Blenheim Road. Builder, Mr. T. Watson, 74 Ruskin Avenue, Manor Park, E.

Four shops and houses are in High Street, North. Builder, J. Harding, 42 Heigham Road, East Ham, E.

FAILSWORTH (Lancs).—New Congregational Church in Ashton Road (£2,500). Architects—Ogden and Hoy, Manchester.

FEATHERSTONE.—Public baths (£6,000). District Surveyor, Fredk. B. Rothera.

FINCHLEY.—Nine houses at Finchley. Builder, Mr. H. F. Nicholls, Holden Road, Finchley.

FROME (Somerset).—Extensions to the Isolation Hospital. District Surveyor, F. W. Jones.

GLOUCESTERSHIRE.—School at Camomile Green (£3,500). County Architect, Gloucester.

HARROW.—Six shops to be erected in Middle Road. Architect, Mr. E. K. Purchase, 20 Maddox Street, W.

Sixteen houses in Rutland Road. Builder, Mr. W. T. Batchelor, 1 Grove Terrace, Squires Lane, Finchley.

Northwood Urban District Council is to erect new Council offices.

HESTON.—The Heston and Isleworth Education Committee has decided to provide an infant school. A. L. Lang, Architect to Committee.

HILL END (Herts).—The County Asylum is to be enlarged. Builders, Wm. Moss and Sons, Ltd., Loughborough.

HINCKLEY.—The Urban District Council is to expend £2,650 on public baths. District Surveyor, E. H. Crump.

HODDESDON.—County Council School at Rye Park (£2,528). County Surveyor, Herts County Council.

HULL.—New Wesleyan Church at Marfleet (£2,000). Architects, Gelder & Kitchen, 76 Lowgate, Hull; builders, Geo. Jackson & Sons, Witham Street, Hull.

Extensions to the Hull Town Hall (£67,606). Architects, Russell & Cooper, 11 Gray's Inn Road, W.C.; builders, Quibble, Son and Greenwood, Sculcoates Lane, Hull.

LIVERPOOL.—The Midland Railway Co. has lodged plans with the Corporation for the erection of an hotel, &c. (£500,000).

WESTOFT.—Messrs. Spiers & Pond, Ltd., [illegible] extension works to their motor garage, Kirkley Cliff Road.

MELTON MOWBRAY.—Improvements at the cattle market (£3,500). District Surveyor, E. Jeeves.

MITCHAM.—Wesleyan Church. Builder, G. E. Everitt, 79 Windmill Road, Croydon.

NEWCASTLE-ON-TYNE.—The Walker Hospital is to be extended at an estimated cost of £5,500.

NORBURY.—The London County Council is to erect 65 cottages at Norbury. Builders, W. Smith & Sons, Croydon.

NORTHFIELD (Birmingham).—Business premises in Bristol Road and Bell Lane (£1,640). (G. Huins & Son, Pool Place, Redditch, builders); business premises in Bristol Road (£850). (G. A. James, Saw Yard, Northfield, builder). Architect, B. Perrins, Evesham Street, Redditch.

PENCOED.—Infants' school (£2,880), for Glamorgan Education Authority. Architect, D. Pugh-Jones, Cardiff; builder, Stephen Shail, Station Road, Llandaff.

PONTYCYMMER.—Higher elementary school (£7,750), for Glamorgan Education Authority. Architect, D. Pugh-Jones, Cardiff; builders, F. W. Lougher & Co., Pontycymmer, Glamorganshire.

ROCHDALE.—Police station (£1,420). S. S. Platt, Surveyor to Corporation, Rochdale.

SALOP.—Schools are to be erected (1) at Ludlow (£5,000), and Whitchurch (£6,000). E. C. Peele, secretary County Education Committee, Shrewsbury.

SMETHWICK.—Corporation depôt buildings (£4,050). Borough Surveyor, C. J. Fox, Allin.

STEVENAGE (HERTS).—School with accommodation for 336 boys. County Surveyor.

SUTTON.—Church of England at Burgh Heath (£5,000). Builders, L. H. & R. Roberts, Islington.

SWANSEA.—Alterations at Oxford Street National Schools.

Six houses in Hazel Row. Builders, W. Williams & Sons, 31 Oxford Street, Swansea.

Additions to the Orphan Home in Northampton Lane.

WEST HAM.—Hall and Sunday school is to be erected for the Rev. Canon Pelly (£3,150). Architect, Percy K. Allen, Lyndhurst Gardens, Tunbridge Wells.

West Ham Education Committee has decided to enlarge St. James's and Custom House Schools. F. E. Hilleary, clerk to the Education Committee.

WILLESDEN.—Addition to Langley House Laundry, 5 Bourke Road, for C. Batty.

Two warehouses in Salusbury Road, Willesden. Architects, Scott & Fraser, 10 Basinghall Street, E.C.

WOLVERHAMPTON.—New schools (£30,000); new public baths (£10,200). The Corporation.

WOOLWICH.—Buildings on the common for the Royal Army Medical Corps (£12,500). H.M. Office of Works, Storeys Gate, S.W.

YORK.—Mr. W. H. Brierley, 13 Lendal, York, is the architect for a secondary school at Sycamore Terrace.

London Traffic Board.—It was stated at the meeting of the London County Council yesterday that the Prime Minister has expressed his willingness to receive a deputation from the Council on the subject of London Traffic after the reassembling of Parliament for the Autumn Session.

Telegraph Traffic.—There are no interruptions of either submarine cables or landlines to report, but there are a few cables still requiring repair. President Castro has placed an embargo on Curaçao, the Dutch island in the West Indies, and this, we take it, is a further obstructive step against the Compagnie Française des Cables Télégraphique, who have been delivering cablegrams from Curaçao by placing them in the post or sending them by boats to their destination. Senders of cablegrams to Venezuela had, of course, to fully address their messages to enable this to be done, and they must be desirous that something should be done to put an end to the quarrel existing between the Venezuelan Government and the French company. In consequence of this quarrel, the company's lines have been closed on Venezuelan territory since Jan. 12th, 1906. This last move will mean that telegrams will have to be despatched from some island further away than Trinidad and Curaçao, and probably the next trial will be from Puerto Rico, the island under control of the United States. It is, indeed, curious that the existing conditions have been so long permitted.

TENDERS RECEIVED AND ACCEPTED

AUSTRALIA.—The Adelaide Municipal Tramway Trust have accepted the tender of the British Insulated & Helsby Cables, Ltd. (Melbourne), at £25,806, for the supply of overhead equipment telephone system, &c.

The Victoria Public Works Department have accepted the tender of E. Bridger for the installation of electric light at the Sunbury Lunatic Asylum at £379.

BRISTOL.—The following tenders have been accepted:—British Thomson-Houston Co., extra high-tension and low-tension switchgear for Avonmouth sub-station, £2,255; Frank Chown (Bristol), concrete gallery for power distribution board at Avonbank, £112; Messrs. Harrison Colmer, Ltd., extension of switchboard gallery at Avonmouth, £312; Messrs. Geipel & Co., supply of arc lamp carbons during the year 1908-9, £318.

GILLINGHAM.—The tender of Messrs. W. Cory & Sons for Hillhouse washed nuts at 15s. 3d. per ton has been accepted.

GLASGOW.—The Magneta Co. have received an order from his Majesty's Office of Works to install the Magneta electric time system in all Glasgow sub-post offices.

LONDON: *London County Council.*—Tenders were invited from seven selected firms for the supply of switchgear at the central car repair depôt, but only Messrs. Spagnoletti & Co., Ltd. (£636), and Messrs. Johnson & Phillips, Ltd. (£700) sent in offers. The Highways Committee recommend the acceptance of the former.

Mr. S. P. Hutton, whose tender for cast-iron insulator frames and covers was accepted last month at £713 15s., has been allowed to withdraw his offer, and the Highways Committee have accepted the next lowest tender, namely, that of the Falkirk Iron Co., at £910.

Hackney.—After considering tenders for the supply of lubricating oils to the electricity works, the Borough Council has decided that the present arrangement with Messrs. Belliss & Morcom be continued to March 31st, 1909. The oils at present in use are supplied by Belliss & Morcom and Messrs. Willcox & Co., and the Electric Lighting Committee reported at the last meeting of the Council that they had given every satisfaction.

Stoke Newington.—The Electricity Committee have received the following tenders for the supply of an engine and dynamo for the new generating station:—W. H. Allen, Son & Co., Ltd., £794; Belliss & Morcom, Ltd. (provisionally accepted), £770; Browett, Lindley & Co., Ltd., £758 17s. For the erection of the building itself the Committee have provisionally accepted the tender of J. Grover & Son at £418, and for the switching apparatus that of Nalder Bros. & Thompson, Ltd., at £183 10s. For the provision of a booster at the sub-station in Edwards Lane the following tenders were received:—Thomas Parker, Ltd., £427; Lawrence, Scott & Co., Ltd., £390; Siemens Bros.' Dynamo Works, Ltd., £388; Lancashire Dynamo & Motor Co., Ltd. (provisionally accepted), £331; Phœnix Dynamo Manufacturing Co., Ltd., £246.

MALVERN.—The Council have accepted the tender of the Electrical Construction Co. for combined 50 kw. steam alternator with Belliss engine.

MALTON.—The tender of the Northern Counties Electricity Supply Co. for public lighting at £400 per annum, under an agreement for three years, has been accepted. The agreement runs from August 1st until May 31st in each year, and specifies the lighting hours.

RAWTENSTALL.—The following tenders have been accepted in connection with the reconstruction of the tramways for electric traction:—Cables, Messrs. W. T. Glover, £21,920; steam dynamos, Messrs. Browett, Lindley & Co., £4,683; transformers, British Westinghouse Co., £1,008; boilers and condensers, Messrs. Yates & Thom, £5,418; generating station buildings, Messrs. Dryland & Preston, £7,503; reconstruction of permanent way, W. Underwood, £39,040; overhead equipment, British Insulated & Helsby Cables.

RHYL.—The tender of the Bradford Electrical Engineering Co. for electrical wiring has been accepted by the Council.

ST. ANDREWS.—The following tenders have been accepted in connection with the additions to the electrical plant of the Fife and Kinross Lunacy Board:—Ironwork and economiser, Messrs. Green & Co., £104; injector piping and valves, and renewal of boiler covering, Mr. D. Houston (Cupar), £54; generating plant, Messrs. Crompton & Co., £252; brickwork and building economiser, Mr. J. Stark (Cupar), £28.

STRATFORD.—The tender of G. N. Haden & Sons, at £106, has been accepted for the installation of electric lighting in a portion of the West Ham and East London Hospital.

TAUNTON.—The tender of Messrs. Bradford & Son for the supply of 2,500 tons of coal from the Glasbrook Colliery at 14s. 10d. per ton has been accepted.

THAMES DITTON.—The District Council at their last meeting accepted the tender for installing an alarm system in connection with the Esher detachment of the local fire brigade of Messrs. Stuart & Moore at a yearly payment of £13 5s., including maintenance, on a five years' contract.

WILLESDEN.—The District Council on Tuesday accepted the tender of Duncan, Watson & Co. to maintain the internal telephones in the public offices for £6 10s. per annum.

COMPANIES' MEETINGS AND REPORTS

ANGLO-ARGENTINE TRAMWAYS CO.—An extraordinary general meeting was held on Wednesday last week in London to confirm resolutions for the creation of capital for the acquisition of the interests of the Compagnie Générale de Tramways de Buenos Ayres, and to make the necessary consequential alterations in the Articles of Associations. The resolutions were carried.

BERLINER ELEKTROMOBIL-DROSCHKEN-A.-G.—The report of this cab company for the year 1907 stated that the cars owned by the company consist of 188 public cabs, 41 private cars, and 5 special cars. Owing to the three months' strike during 1907, the report showed a loss of 253,080 mk., including the losses in 1906. The results of the first five months of working for the year 1908 show a gross income of 895,000 mk. against 390,000 mk. for the corresponding period of last year. The gross profit amounts to 280,000 mk., from which, however, an amount for renewals, &c., will have to be deducted. If the results for the remaining seven months are equally as good, the losses at least will be redeemed, and better results may be expected in the following year.

BOMBAY ELECTRIC SUPPLY AND TRAMWAYS CO.—The report for 1907 states that the total revenue for the year amounted to £127,920. After deducting all revenue expenses, including £700 the instalment written off the electricity supply suspense account, interest on loans and a proportion of debenture interest amounting to £12,725, there remains the sum of £29,537, in addition to £1,363 brought forward from last account, making an available total of £30,701. The dividend on the 6 per cent. cumulative preference shares to December 31st absorbs £27,764, leaving a balance of £2,936 to be carried forward. The receipts derived from the tramways amounted to £105,503, as compared with £101,051 in 1906. The working expenses in Bombay amounted to £61,112, as compared with £56,955 for the previous year. The increase in receipts is due to the increased route mileage worked, and to the establishment of electric traction on a portion of the system, but the unavoidable mixing of the two services has much hampered both. The increase in the working expenses is partly accounted for by the increased mileage worked, but it is chiefly due to simultaneously carrying on two separate services, horse and electric traction, each to a large extent requiring its own organisation. The first portion of the reconstructed tramways from Colaba Terminus to Crawford Market, 2·58 route miles, was opened for traffic by electric traction in May, 1907, and additional routes, as they were completed, were worked by electric traction. At December 31st last, 13·32 miles of route were being worked by electric traction, including 2·69 miles of the authorised extensions. The remainder of the system, 7·37 miles, including 0·35 mile of extensions, was worked by horses, the horse cars also running over a portion of the electrified route. Since the close of the year the electrification of the remaining routes has been completed, and from May 18th the entire system, comprising 20·69 route miles, has been working by electric traction. With the exception of half a mile the tramways are double track throughout. The company has anticipated by three months the period prescribed under the concession with the Bombay Municipality for the completion of the reconstruction of the tramways. The gross traffic receipts since the close of the year show a continued increase, the comparative figures being:—From January 1st, 1908, to June 4th, £53,351; corresponding period, 1907, £42,830: an increase of £10,501. Gross receipts from electric supply for the year amounted to £21,566, as compared with £8,435 for the previous year. The receipts, exclusive of the amount represented by the current supplied for the tramways, have increased by more than 100 per cent. over those for the previous year. Working expenses amounted to £19,346, as compared with £10,075 for the previous year. There is a credit balance of £2,021, compared with a debit balance of £1,659 for the pre-

Digitized by Google

vious year. The total capital expenditure to December 31st last stands at £1,547,060. The balance of £4 per share has been called up on the preference shares. 7,350 ordinary shares have also been issued during the year, leaving a balance of 25,643 ordinary shares unissued at December 31st last. In order to provide the funds required to discharge the company's obligations incurred in connection with the electrification and extention of the tramways and in the development of the electric supply business, the directors, since the close of the year, concluded arrangements with a syndicate in Bombay to take up the balance of the ordinary shares, to which effect has since been given. These shares were offered by the syndicate for subscription in Bombay in February last. The meeting is on Tuesday.

At the annual meeting on Tuesday the report and accounts were adopted.

BRUCE PEEBLES & CO.—Meetings of the debenture-holders and creditors were held in Edinburgh on Saturday, when the scheme of reconstruction, already outlined in our columns, was approved.

CHILI TELEPHONE CO.—The report for the year ended March 31st, 1908, shows that the number of subscribers on the books of the company was 7,666, a gain of 551 for the year. The gross revenue in Chili was $1,469,611, an increase of $300,123, whilst the expenditure was $744,121, an increase of $95,572. The net income shows an increase of $204,551. Converted into sterling there is a balance of revenue, including £2,727 brought forward from last year, of £33,817, of which £13,440 has been carried to reserve. An interim dividend of 3s. per share, free of income tax, was paid in January, and a final dividend of 5s. per share, free of income tax, is now recommended, carrying forward £2,777.

At the meeting on Thursday the report and accounts were adopted.

CITY & SOUTH LONDON RAILWAY CO.—The report for the June half-year states that the receipts from all sources have amounted to £88,501 and the cost of working £40,964, leaving a profit of £47,536. Inclusive of the balance brought forward from December 31st last, the net revenue account shows an aggregate total of £48,656. After making provision for the debenture stock interest, rent charge, and the transfer to the renewal fund of £1,500, a balance remains available for dividend of £32,999. Out of this sum the directors recommend that the full dividend of 5 per cent. per annum be paid on the preference stocks, 1891, 1896, 1901 and 1903, and that a dividend at the rate of 1½ per cent. per annum be paid upon the consolidated ordinary stock for the half-year, leaving a balance of £1,868 to be carried forward to the next account. The following number of passengers, exclusive of season ticket holders, carried since the opening of the railway, amounts to 201,801,061, and the total dividends paid amount to £1,606,651. The number of passengers carried during the past half-year was 10,891,535, the most that has yet been carried in any half-year. The receipts for the half-year have been unfavourably affected by various causes. The weather in May and June has been finer and warmer than in 1907; an exhibition at the Agricultural Hall in the summer of 1907 proved far more attractive to the public than that which has been held in the corresponding part of this year; and the London County Council's electrified tramways from Moorgate to King's Cross, and past the Angel to Highbury, were opened for traffic in July, 1907. And since April 10th, 1908, the London County Council tramways on the south side of the Thames have been placed in direct communication, by way of Westminster Bridge, with the Angel and Highbury through the completion of the subway from the Victoria Embankment to Theobalds Road. The lower price of coal has only to a limited extent influenced the working of the half-year. With the exception of a sum of about £2,800, the whole of the charges for the extension to Euston, the new works at Stockwell, and the two new trains of five coaches each, ordered in the month of July, 1907, have now been paid.

CROMPTON & CO.—The annual statement of accounts and balance sheet to March 31st last, shows that the output from the company's works at Chelmsford during the financial year shows a large advance over that of any previous year, and at the same time further economies in the cost of manufacture have been introduced. There is a considerable increase also in the turnover of the sales department, and some important contracts have been carried out during the year. The net profit for the year amounts to £31,220 (as compared with £38,291 for the year ending March 31st, 1907, and £20,060 for the year ending March 31st, 1906), and from this figure has been deducted the sum of £1,211, representing a loss on old type stock, which, owing to the introduction of improved designs, it has been thought advisable to dispose of at less than cost. After providing for debenture interest, and other items shown in the net revenue account, there remains, with the sum brought forward from last year, an available balance of £28,216. In view of the continued keen competition and low prices, and the general depression in trade experienced during the latter part of the year, the directors are of opinion that the results of the year's working are satisfactory. The directors propose to recommend a dividend at the rate of 5 per cent. per annum for the year, to provide £2,000 for doubtful debts and contingencies, to place £8,000 to reserve, bringing that account up to £28,185, and to carry the balance, £6,103, forward. The undertakings of the Electric Supply Corporation continue to make progress. A further sum of £9,687 has been invested during the year in shares of the guaranteeing company referred to in the report for the year ending March 31st, 1905, but the directors anticipate a substantial reduction in the amounts which will be required for the remaining two years, during which the guarantee has to run. Any possible loss on this head is partly covered by insurance, which, with the further amount proposed to be placed to reserve out of the year's profits, will, in the opinion of the directors, afford ample provision for this item. The meeting will be held on Monday.

EAST LONDON RAILWAY CO.—The report for the six months ended April 30th, 1908, states that owing to the cessation of through train service from the Metropolitan Railway, the diminution in receipts from passenger traffic continues. Having regard to the serious losses sustained, the lessee companies have been giving the question of electric traction close attention, and the electrical engineers to the Metropolitan Railway and the Great Eastern Railway Companies respectively, Mr. C. Jones and Mr. H. W. Firth, have prepared a comprehensive report as to the best system of dealing with the railway from the point of view of electric traction. This report has been referred to the general managers of the lessee companies, who will report to the Joint Committee. No definite conclusion has been arrived at yet, but the directors state that they have some confidence that the result of the deliberations will have some effect in the near future.

ELECTRIC CONSTRUCTION CO.—At the annual meeting on Monday, the report and accounts given in our last issue were adopted. Mr. W. S. B. McLaren, who presided, drew attention to the greatly improved position of the company compared with 12 months ago.

ELECTRIC & GENERAL INVESTMENT CO.—For the year ended May 31st, 1908, there was a gross profit of £7,891. After meeting all general charges, the interim dividend already paid on the preference shares, and the final dividend upon the latter, there remains a balance of £568, which has been carried to the contingency fund, raising this to £67,556. Owing to the unfavourable financial conditions which have prevailed in the electrical industry during the past year, the revenue has been mainly derived from investments and fees for acting as trustees. The trustees for the ordinary share reserve fund propose to distribute 6d. per share out of the dividends received on the trust investments, whilst the trustees for the founders' shares reserve fund propose to distribute £10 per share. The scheme of reconstruction outlined in the directors' report last year, and submitted to the shareholders in 1907, failed to meet with the preference and founders' shareholders approval, and the matter therefore remains in abeyance.

ELECTRICAL POWER STORAGE CO.—Mr. F. Green, presided at the annual meeting of this company on Thursday, when the report and accounts given in our last issue were adopted. With regard to the falling off during the past year, the chairman pointed out that this was most noticeable since November, when the money panic took place. Up to date, however, they were ahead of the previous year in output, but the most disturbing influence was the absence of large contracts, which had brought about a keenness of competition which he described as suicidal

ELEKTRICITATS-AKT. GES. VORM. W. LAHMEYER & CO., FRANKFORT A.-M.—At the general meeting held recently, the report for the year was adopted, and a dividend of 7 per cent. declared, which is the same as that of last year.

GENERAL ELECTRIC CO.—The report for the year ended March 30th, 1908, shows a net trading profit, including income from investments, &c., of £59,753. A balance of £34,723 remains after deducting depreciation and debenture interest. The directors recommend appropriation as provision for Managing Director's and employees' bonus of £2,223, and the payment of a dividend of 5 per cent. upon the ordinary shares, carrying forward £1,974 to reserve fund. This latter will then amount to £120,343. The report states that the feature of the year has been the sudden fall in the price of raw materials, which has adversely affected the results of several departments and necessitated a considerable writing down of stocks. Mr. M. Byng has resigned the chairmanship of the company, and Mr. E. G. Byng has been appointed a director. The meeting is to-morrow.

GROSSE BERLINER STRASSENBAHNEN.—The report for the year 1907 contains the following information. The total length of single-track now amounts to 522 km. The rolling-stock consists of 574 four-axle and 917 two-axle motor-cars, 1,001 trailers, and 190 special cars. The number of car-kilometers amounted to 85,718,000, or 3·4 per cent. higher than the figure the previous year. The number of passengers carried during the year exceeded 378 million. The total receipts amounted to 36,000,000 marks, and the total expenses to 20,250,000, leaving a surplus of 16,330,000 marks. The share-capital of the undertaking has increased from 44 million marks in 1898 to 100 million marks in 1907.

PARLIAMENTARY INTELLIGENCE

CENTRAL IRELAND ELECTRIC POWER BILL.—A House of Commons Committee presided over by Lord Donoughmore had this Bill under consideration last week. We have already reported fully the proceedings before the House of Commons Committee, the Bill being at first rejected mainly on the opposition of the Dublin Corporation and on financial grounds, but was afterwards recommitted with Dublin struck out of the area and a stronger financial case. As a consequence, the original capital of £450,000 with borrowing powers was reduced to £150,000 with borrowing powers. It is made a condition in the Bill that before any powers can be exercised £50,000 must be subscribed. The object of the Bill is to erect an electricity works upon the Grand Canal, Co. Kildare, close to Robertstown, to make use of the peat in the district for working gas producers, the generating plant being driven by gas engines. The Company propose to make use of a process now commonly used in Germany and various other parts of the Continent, by which peat is used whilst it still contains 50 per cent, to 60 per cent. of its moisture. It is estimated that the cost of fuel will be 0.05d. per unit. The area includes 7,000 acres of bog land, of which it is proposed at first to purchase 500 acres, there being a depth of peat of 25 ft. Captain H. Riall Sankey, Mr. A. Lupton, M.P., Mr. Crossley, M.P. (chairman of Messrs. Crossley Bros.), and Mr. J. Sturgeon again gave evidence in favour of the Bill, the only opposition being by the Dublin and Alliance Gas Company, whose case rested on the plea of unfair competition. Mr. Stephen Sellon was called by the Gas Company, and expressed the opinion that the scheme could not be financially sound, but the Committee passed the preamble, and reported the Bill for third reading. Full particulars of the previous proceedings will be found in ELECTRICAL ENGINEERING, Vol. III., pages 503 and 803.

FIRES ON TUBE RAILWAYS.—In answer to a question in the House of Commons on Wednesday last week, the President of the Board of Trade said that special requirements had been made regarding the construction of tube railways with the object of guarding against risk of fire. These, however, related to materials, ventilation, insulation, lighting, and similar matters, but he did not think knowledge of these details by the passengers would add to safety. Hydrants and fire hoses were fixed on every platform, and fire extinguishers were carried in every carriage.

LONDON COUNTY COUNCIL TRAMWAYS AND IMPROVEMENTS BILL.—When this Bill came up for third reading in the House of Commons on Tuesday Mr. Timothy Davies moved that the second reading be deferred for three months. He said his objection was to the clause authorising the construction of overhead tramways in Fulham, a bargain having been come to with the Borough Council that the conduit system should be adopted. Mr. Guinness and Mr. Waterlow opposed the amendment mainly on the ground that the Fulham Borough Council did not oppose the Bill in Committee of either House, and that the third reading stage was not a desirable time to bring such matters forward. The amendment was then withdrawn, and the Bill read a third time.

LONDON ELECTRIC POWER BILLS.—The Barnes and Croydon Corporations have deposited petitions in the House of Commons against the London and District Electricity Supply Bill.

The London (Westminster & Kensington) Electric Supply Bill and the London Electric Supply Bill were read a third time and passed in the House of Lords on Monday.

LONDON UNITED TRAMWAYS BILL.—We report the proceedings on this Bill before the House of Lords Committee on Tuesday on page 153.

METROPOLITAN ELECTRIC TRAMWAYS BILL.—We report the proceedings before the Unopposed Committee of the House of Commons on Thursday on page 153.

PROGRESS OF ELECTRICAL BILLS.—The Macclesfield and District Tramways (Abandonment) Bill was read a second time in the House of Lords on Wednesday last week.

The Telegraph Construction Bill was read a first time in the House of Lords on Wednesday last week.

The Nottinghamshire and Derbyshire Tramways (No. 2) Bill was read a second time in the House of Commons on Tuesday last week, and a first time in the House of Lords on the same day.

The Metropolitan District Railway Bill was read a third time in the House of Commons on Friday.

The South Wales Electrical Power Distribution Bill was read a third time and passed in the House of Commons on Thursday.

The Wishaw Burgh Electricity Bill was read a third time in the House of Lords on Thursday.

TRAWLERS AND TELEGRAPH CABLES.—In the House of Commons on Monday Mr. Beauchamp asked the Postmaster-General whether the Commercial Cable Co. had any authority to issue warnings against trawling on the south-west coast of Ireland. The Postmaster-General replied to the effect that having appointed a Committee to inquire into the whole question, which was now taking evidence, the matter would be referred to them. (We gave the names of the Committee and the terms of reference in our last issue.)

UNOPPOSED BILLS.—Electric Lighting Provisional Order Confirmation Bill, No. 3, and Tramways Provisional Order Confirmation Bill, No. 2, were passed by the Unopposed Committee of the House of Commons on Tuesday.

The Committee also considered the Great Northern Piccadilly & Brompton Railway Bill, which provides for an amendment of the agreement with the Underground Electric Railway Co. of London, dated January 13th, 1905, and for the cancellation of 430,000 cumulative preference shares and their conversion into 4 per cent. preference shares. The Bill was ordered to be reported for third reading.

The Macclesfield & District Tramways (Abandonment) Bill was ordered to be reported for third reading by the Unopposed Committee of the House of Lords on Tuesday.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £59 10s. to £60 per ton (last week £59 to £59 10s. per ton).

GT. CENTRAL RAILWAY.—The Gt. Central Railway Co. have issued a most exhaustive selection of excursions on all parts of their system in the form of an A.B.C. programme.

LONDON PRIVATE FIRE BRIGADE.—At the annual competition of the London Private Fire Brigades at the Crystal Palace, on Saturday, the Robertson Fire Brigade (Robertson Electric Lamps, Ltd., Hammersmith) again won the shield presented by Sir T. R. Dewar for the best drill. In the championship totals, the Robertson Brigade came out second against 23 competing brigades, their aggregate time for all the drills being 348 seconds against 342 by the winning brigade.

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—At the London Bankruptcy Court last week, J. T. Murray, of West Kensington, came up for public examination. The statement of affairs showed liabilities of £3,212 and assets £73, but there were bad book debts amounting to £30,250. The debtor attributed his position to losses sustained during the last five years in the formation of a tramway company, and he has also been concerned in the formation of the Blackpool garage and General Electrical Engineering Co., Ltd. The first meeting of creditors has been adjourned to enable the debtor to make arrangements with a view to discharging his liabilities.

A meeting of creditors in the voluntary liquidation, for the purpose of reconstruction, of Messrs. Thomas Parker, Ltd., will be held at the offices of the company, Wednesfield Road, Wolverhampton, on Thursday next, July 30th, at 12.30. This is a formal meeting. Since the circular we gave last week, the chairman of the company, Mr. C. T. Mander, has been appointed receiver and manager for the debenture holders, and is carrying on the business until the necessary formalities are completed, and the new company, the Rees Roturbo Manufacturing Co., is formed.

A petition for the winding up of Messrs. Meldrum Bros. will be heard before Mr. Justice Swinfen Eady at the Royal Courts of Justice, Strand, London, on July 28th. Any person intending to appear must give notice to Mr. A. M. Longhurst, 2 Fenchurch Buildings, London, the agent for Messrs. Stratton and Son, Wolverhampton, solicitors for the petitioners.

Creditors of the Lancashire Electric Supply Company are requested to send in particulars of their claims by August 7th to Mr. J. Collier, 4 Chapel Walks, Manchester, the liquidator.

A general meeting of the South-Western Electrical Company will be held at the offices of Messrs. Alles, Salamon & Co., 1 Oxford Court, Cannon Street, on August 21st, at 12 noon, to hear the liquidator's account of the winding up.

The trustee in the bankruptcy of Mr. A. J. Harris, electrical engineer, of Borough Mills, Bower Street, Bradford, has been released.

The Seville Tramways Co. is to be wound up voluntarily. Mr. A. F. Judd is liquidator. A meeting is to be held on Monday at 23 Talbot Road, Highgate, at 3 p.m., to consider whether an application shall be made to the Courts for the appointment of a liquidator in the place of, or jointly with, Mr. Judd.

OUTINGS.—The annual outing of the Sun Electrical Co., Ltd., took place on Saturday, July 11th, in the form of an up-river trip to Hurley. The electric launch *Rosalind* left Maidenhead Bridge at 10.15 a.m., luncheon being served at the George and Dragon Hotel, Marlow. Mr. A. G. Beaver, the manager, proposed "The Sun Electrical Co., Ltd.," and expressed his satisfaction with the success which had attended the introduction of the "Kalkos" system of tubing during the past year, and predicted a great future for it. Tea was partaken of at "Ye Olde Bell," Hurley, after which the return journey was made, Paddington being reached just before 11 o'clock.

On Saturday, the 18th inst., Messrs. E. P. Allam & Co., Red Lion Street, held their annual works outing at Rye House, the excursion being attended by all the employés, including the office staff, departmental managers, and agents.

MISCELLANEOUS CITY NOTES

ANGLO-AMERICAN TELEGRAPH CO.—After placing £5,000 to the credit of the renewal fund, an interim dividend for the quarter ending June 30th, 1908, of 15s. per cent. on the ordinary stock and £1 10s. per cent. on the preferred stock, less income tax, is recommended. After paying the foregoing dividends, there will be a balance of £6,962 to be carried forward to the next account.

ANGLO-ARGENTINE TRAMWAYS CO.—A provisional agreement has been arrived at with the Compagnie Générale de Tramways de Buenos Ayres for the acquisition of all the issued share capital of the Buenos Ayres Electric Tramways (1901), Ltd., and the entire undertaking of the Belga Argentine Tramways Co., the consideration being £1,400,000 in fully-paid new ordinary shares. It is further proposed that the £5,000,000 new ordinary shares already authorised shall be divided into £2,500,000 five per cent. cumulative third preference shares, and £2,500,000 ordinary shares, and that the payment for the properties above mentioned, and also for the Buenos Ayres and Belgrano Tramways Co., shall be made as to one-half in third preference shares and one-half in ordinary shares.

BOURNEMOUTH & POOLE ELECTRICITY SUPPLY CO.—An interim dividend of 5 per cent. per annum, less income tax, is recommended upon the ordinary shares for the June half-year.

BRITISH COLUMBIA ELECTRIC RAILWAY CO.—It is announced that the issue of new shares has been largely over applied for, and that consequently some delay was incurred before letters of allotment and regret could be posted.

COUNTY OF LONDON ELECTRIC SUPPLY CO.—An interim dividend at the rate of 4 per cent. per annum, less tax, has been declared upon the ordinary shares for the June half-year.

DIRECT UNITED STATES CABLE CO.—A final dividend of 4s. per share, together with a bonus of a shilling per share, both free of income tax, making, with the three interim dividends already paid, 4½ per cent. for the year ended June 30th, is recommended. The sum of £5,000 is placed to reserve fund, carrying forward £2,812.

EDMUNDSON'S ELECTRICITY CORPORATION.—An issue is announced of £100,000 five per cent. prior lien debenture stock at par redeemable at the option of the company at any time after March 31st, 1912, upon six months' notice in writing, at 105 per cent. until 1920, and thereafter at par, and similarly redeemable in the event of voluntary liquidation of the company. Provision is also made for the redemption of the stock by means of cumulative sinking fund of 1 per cent. commencing July, 1912, to be applied in the purchase of stock, or in redemption by drawings at 105 per cent until 1920, and thereafter at par. The stock, which is offered for subscription on behalf of Edmundson's Electricity Corporation, Ltd., by the Electric and General Investment Co., is secured by a trust deed in favour of the trustees, by which it is constituted a specific first charge on certain debentures and debenture stock of the face value of £92,700 in various electric supply companies, and a first floating charge upon the undertaking and remaining property of the company. Power is reserved, however, to issue further stock ranking *pari passu* with the present issue to a total amount not exceeding £200,000, including the £100,000 now offered.

ELECTROMOBILE HIRING CO.—In consequence of the shares in this company now being held by or on behalf of the Electromobile Co., Ltd., the two companies are to be amalgamated. Mr. George Cockerton, 7 Hertford Street, Mayfair, London, secretary of the Electromobile Hiring Co., has been appointed liquidator in the voluntary winding up of this company.

LONDON STREET TRAMWAYS CO.—An interim dividend of 2s. per share, free of tax, upon the ordinary shares for the past half-year is recommended.

MALTA TRAMWAYS CO.—A prospectus has been issued inviting applications for £125,000 ordinary shares of £1 each at par.

MELBOURNE TRAMWAYS & OMNIBUS CO.—The London secretary has received cable advice of the declaration of a bonus for the year ended June 30th by the rate of 5 per cent.

MONTREAL LIGHT, HEAT & POWER CO.—The holders of 4½ per cent. first mortgage bonds, allotment letters, and scrip are notified that the bonds are now ready for exchange. Allotment letters and scrips must be left at the Bank of Montreal, 47 Threadneedle Street, London, three clear days for examination, and forms for listing may be had on application.

A dividend of 1½ per cent., being at the rate of 6 per cent. per annum for the quarter ending July 31st, has been declared.

ST. JAMES' & PALL MALL ELECTRIC LIGHT CO.—An interim dividend for the June half year at the rate of 10 per cent. per annum on the ordinary shares has been declared.

TORONTO POWER CO.—Applications are invited for an issue of £500,000 4½ per cent. redeemable debenture stock at 98.

UNDERGROUND ELECTRIC RAILWAYS CO. OF LONDON.—In the Chancery Division on Thursday Mr. Justice Swinfen Eady made an order confirming the scheme already given in our columns which has for its object the reorganisation of the company's financial position. There was opposition from some of the note holders but in giving judgment his Lordship said it was the duty of the Court to consider whether the scheme was a reasonable compromise and one which could be regarded as beneficial to both sides. The creditors had approved of the scheme by an overwhelming majority, but at the same time this did not prevent the minority from having their rights and interests protected, and if it was not a fair and reasonable scheme the Court would be bound to reject it. After careful consideration, however, he was quite satisfied that the opponents of the scheme, as well as those who approved it, were fairly dealt with.

WALSALL ELECTRICAL CO. (and reduced).—A petition has been presented to the High Courts confirming a resolution reducing the capital of the company from £25,000 in £1 shares to £20,620 in £1 shares. The petition will be heard by Mr. Justice Swinfen Eady on July 28th.

APPOINTMENTS AND PERSONAL NOTES

Messrs. Souper & Callaghan, Engineers and Agents, of 46 Grosvenor Chambers, Deansgate, Manchester, have entered into partnership for the purpose of carrying on business as buying and selling agents for all classes of machinery and engineering materials and supplies.

The local staff of the Manchester branch of Siemens Bros.' Dynamo Works, Ltd., has presented Mr. Philip C. Pope with a very handsome gold watch, on the occasion of his resigning his position as manager of the branch office. Mr. Edmund L. Hill, who has been appointed to take Mr. Pope's position, made the presentation before the whole of the staff. We understand Mr. Pope is leaving Siemens Brothers' Dynamo Works, Ltd., to take up a position with Messrs. John Musgrave & Sons, engineers, of Bolton.

The Finchley Urban District Council has agreed that the salary of the Electrical Engineer (Mr. E. Calvert) be increased from £450 to £475 per annum, such increment to take effect from July 1st.

Mr. William Corin, Launceston, Tasmania, has been appointed electrical engineer to the Public Works Department, Sydney (N.S.W.), at a salary of £750 per annum.

THE G.B. SURFACE CONTACT SYSTEM

THE tramcars which have been running during the past few weeks upon the G.B. Surface Contact system from Whitechapel to Bow have been withdrawn, and there is a rumour to the effect that the Highways Committee of the London County Council is in favour of the abandonment of the experiment. At yesterday's meeting of the London County Council, Sir John Benn endeavoured to raise the question, but was ruled out of order. Later in the day Mr. Whittaker Thompson, the chairman of the Highways Committee, is said to have stated that in consequence of reports from the officers of the Council as to the accidents upon the system, the Committee had decided to recommend the Council to cease using the system. We understand that a full report dealing with the matter will be presented to the Council at the next meeting.

In the House of Commons on Tuesday, in answer to Mr. B. S. Straus, Mr. Winston Churchill stated that the Board of Trade had been informed by the London County Council of an accident to a horse through coming in contact with a stud upon the G.B. Surface Contact system in the Mile End Road. This system had been sanctioned as an experiment for six months from June 25rd, and if a renewal of the Board's sanction was desired at the end of that period, the nature and number of any accidents that had occurred would be a factor in the consideration of the question.

Wireless Telegraphy.—The *Western Morning News* states that orders have been received directing that the wireless telegraph offices on board battleships, which are exposed to the blast of heavy guns, are to have their doors made of 10 lb. steel plating, suitably stiffened, without windows in the doors. These alterations are to be carried out in all vessels fitted with wireless telegraph apparatus as they come into the dockyard hands.

Projected Swiss Electric Railway.—According to *The Engineer*, the Bernese Alps Railway Company have granted 1,000,000 francs for the immediate adoption of electric traction on the line Spiez Frutigen. The scheme is to be carried out at once, both as an experiment and with the special object of training the staff. Single-phase currents of 15,000 volts at 15 periods have been adopted on the proposal of Chief Engineer L. Thormann, of Bern, who decided in favour of this system as the most economical. The energy is to be taken from the power-station of the united Kander and Hagnek Works, in which special turbo-generators are to be installed. The rolling-stock will comprise both locomotives and motor-carriages. It is intended that passenger trains of 250 tons should take the maximum gradient of 27 per cent. at 40 kilometres per hour, and goods trains should travel at 30 kilometres; about 1,200 horsepower, and two or three motors will therefore be required for the motor-carriages of the passenger trains.

SUMMARY

The second reading debate upon the London Electric Power Bills takes place in the House of Commons to-night. There are eight motions down for its rejection, but the Government will not officially oppose. The Board of Trade will move that the London County Council be named in the London and District Bill as the purchasing authority. (Page 166.)

An article communicated by "A Civil Engineer" contains a plea for the more extended use of hard woods, such as Karri and Jarrah for constructional purposes. It is argued that for flooring and even for foundations for certain classes of machinery in generating stations they are particularly suitable, and the suggestion is made that on account of their comparatively non-inflammable nature they might in some cases replace slate for switchboards. (Page 167.)

The reports of H.M. Inspector of Mines show that the number of electrical coal-cutters in use in the collieries of this country, although still under the number of compressed air machines, is increasing at a more rapid rate. (Page 168.)

The report of the Tramways Committee of the Corporation of Glasgow for the year ended May 31st, 1908, shows an increase in the average traffic revenue per car mile from 10·465d. for the year 1906/7, to 10·488d. for the year 1907/8. The working expenses, excluding capital charges, show an increase of 0·172d. per car mile over those of the previous year. The extensions during the past year comprised about one mile of double track, the total length of single track owned and leased by the Corporation amounting to 179 miles. The generating costs have increased from 1·056d. to 1·191d. per unit issued to the sub-stations for traction and car lighting purposes. (Page 169.)

The report of the work of the German Physikalisch-Technische Reichsanstalt for 1907 contains particulars of a large amount of electrical testing and experimental work, including the production and investigation of continuous electrical oscillations by the arc method. Researches have also been carried out on the magnetic properties of iron alloys, and extensive tests on metal filament lamps have been conducted. (Page 170.)

A report of the Highways Committee of the London County Council recommends the abandonment of the experiments in the Mile End Road with the G.B. surface contact system, and suggests the use of the overhead trolley system, which, it is estimated, can be adopted at a further expenditure of about £8,000. The G.B. Surface Contact Co. have sent a long communication to the members of the Council, in which they claim that the cause of the failure of the experiments is the disregard of their advice by the officers of the

Digitized by Google

Council, and they offer to put the installation in proper working order at a cost of not exceeding £2,500, which shall not be paid to them unless the Council continue to use the system. At Tuesday's meeting it was stated that the company have threatened legal proceedings. (Page 171.)

THE results of the experiments in connection with the proposed electrification of the main lines of the Swedish State Railways have been published. The single-phase system was chosen as being the most suitable under the conditions prevailing in Sweden. The behaviour of the equipment is stated to have been most satisfactory. Experiments were made in connection with the rail return indicated that bonding on high-tension single phase railways is unnecessary. Various forms of overhead equipment were tried, but a simple suspension from side brackets, without either cross wires or suspension wires, was considered to be the most satisfactory. No high-speed tests were made. (Page 172.)

A MEETING of the Tramways and Light Railways Association was held on Friday last for the purpose of further discussing the lecture on "Rail Corrugation," delivered by Prof. C. A. CARUS-WILSON at the last meeting of the Annual Congress on July 10th. The discussion was opened by Mr. H. M. SAYERS, who expressed the opinion that intermittent slipping would have the same effect as the intermittent skidding described by the lecturer. Such intermittent slipping could be caused by the sudden rise of motor torque when two or more notches of the controller were passed over without a pause. Mr. J. R. SALTER suggested that the molecular change in the iron rails due to magnetisation might have some influence. The importance of ensuring uniform flange pressure was emphasised by Mr. J. S. WARNER. Mr. S. SELLON objected to the tyre section shown by the lecturer, and called attention to the wear which must take place on the flange and rail-head before check-cutting can occur. He did not think unequal diameters essential for the production of intermittent skidding. The corrugations on the old Brixton cable tramway lines were put forward by Mr. J. WELLING in support of Prof. Carus-Wilson's theory. Prof. CARUS-WILSON replied very completely to all the questions put, and the proceedings terminated. A written communication has been received from Mr. J. A. PANTON. (Page 185.)

THE following books are reviewed in this issue:—"Lead Refining by Electrolysis," by A. G. Betts, and "Die Revision elektrische Starkstrom Anlagen," by Paul Stern. (Page 174.)

AN electric crane installation has recently been carried out at Southampton, in which batteries are used to equalise the load on the generators. (Page 172.)

THE National Telephone Co.'s repair shops at Nottingham are described in an illustrated article. (Page 175.)

IN our fifth illustrated article on matters of electrical interest at the Franco-British Exhibition some further particulars are given of the generating plant in the Machinery Hall, which comprises a large Parson's continuous-current turbo-generator and a Westinghouse gas-engine set, supplied with gas from a Mond producer plant. Details are also given on some applications of electrical power in the Exhibition, including the driving of the "Flip Flap" and the working of the cascade in the Court of Honour by electrically-driven turbine pumps. Some further exhibits, including some of electrometallurgical interest in the French section, are noticed. (Page 177.)

A FEW particulars as to the scope of the Electrical Exhibition at Marseilles, and the current supply thereto, are given in a short article. (Page 181.)

IN an article in a German contemporary by H. REMANÉ, of the Auer Gesellschaft, the probable candle-power of the metal filament lamp which will take the place of the 16 c.p. carbon lamp for general illumination, is considered. Some interesting figures for the dimensions and energy consumption of Osram lamps of various candle-powers and voltages are also given. (Page 182.)

THE annual report of the Board of Trade with respect to electric lighting provisional order applications during 1907 shows that of the 27 applications, 17 were by local authorities, and 10 by companies. (Page 182.)

THE construction of Mr. L. H. WALTER'S tantalum-mercury wave detector was described in a Paper recently read before the Royal Society. Tests of the apparatus in actual practice appear to show that while possibly not so sensitive for very weak oscillations it enables much louder sounds to be produced in the receiving telephone for moderately strong waves than the electrolytic detector, and that it is particularly well suited to wireless telephony. **(Page 188.)**

THE report of the sub-committee appointed by the Tramway Committee of the Dundee Town Council to consider the practicability of using the trackless trolley system in the suburbs of Dundee contains accounts of several similar undertakings on the Continent, and recommends its adoption where the traffic is not sufficient to warrant the laying of tramway track. (Page 184.)

THE accounts of the London County Council for the year ended March 31st, 1908, show total receipts amounting to £1,663,031, and working expenses amounting to £1,170,115. After meeting capital charges, &c., there is a net balance of £45,406, the whole of which, together with the balance of £5,923 brought forward, has been carried to renewals fund. It is pointed out that had the basis for renewals laid down by the Council been adopted, viz., two-thirds of a penny per car mile, the sum of £71,086 would have had to be set aside. (Page 185.)

THE Highways Committee of the London County Council recommend Parliamentary powers being sought for new tramways next session at an estimated cost of £403,430. (Page 185.)

THE refining of the slimes produced at the Raritan Copper Refinery and the production of pure silver and gold therefrom is noticed under "Electrochemistry and Electrometallurgy." The Aluminium Corporation, Ltd., appear to be making good headway. They have started some of the furnaces at Wallsend. They are also building works for the refining of the bauxite, for which a subsidiary company has been formed, and for the manufacture of electrodes. Reference is also made to the preparation of diaphragms. (Page 187.)

UNDER "Electrical Science," in the British and American Section, is a note on a Paper by O. C. CLIFFORD on the magnetic susceptibility of copper-tin alloys. In the Papers abstracted in the Continental Section, GUYE and BRON announce a rule connecting the sensibility of the alternating arc with the atomic weight of the substance constituting the electrodes; GUILLAUME and PERRIN furnish an explanation of the electric fatigue observed by Bose in wires; and J. BECQUEREL anticipates and meets some criticisms of his alleged discovery of free positive electrons. (Page 187.)

A SWITCH for preventing the improper starting and control of motors is the subject of a patent specification by the BRITISH THOMSON-HOUSTON Co., which was published by the Patent Office on Thursday last. The specification describing the "Jandus" enclosed flame arc lamp has also been published. A process for the manufacture of metal filaments consisting of a mixture of silicon and tungsten, and having a higher specific resistance than pure tungsten filaments, is given in a specification by the BRITISH THOMSON-HOUSTON Co. A protective device for high-tension circuits, depending

Digitized by Google

for its operation on the difficulty of maintaining an arc with an electrolyte as a cathode, has been patented by E. L. CREIGHTON. The specification describing the composition used for insulating and impregnating cables and known as "Liconite," the invention of E. S. ALI-COHEN, has also been published. A patent for an electrolytic cell, in which the liquid to be electrolysed flows over a rotating surface consisting of the edges of strips of metal alternately negative and positive, expires during the current week. (Page 189.)

THE accounts of the Bristol electricity undertaking show a net profit of £473 after providing £43,637 capital charges, &c.—There is a gross profit of £6,790 shown by the accounts of the Devonport electricity undertaking for the past year, which is reduced to £7 after meeting capital charges, &c.—The Edinburgh Electric Lighting Committee has decided to transfer £9,794 of the profit of £10,541 upon the electrical undertaking for the past year to the relief of rates.—The accounts of the Manchester Corporation Tramways Department show a gross profit of £269,049, of which capital charges absorb £124,255; reserve, renewals, and depreciation, £87,790; and contribution in aid of rates, £55,000.—The Norwich Corporation electricity accounts show a net profit of £3,104 for the year ended March 31st.—An electrobus is running trials in the streets of York. (Pages 191 to 193.)

THE London County Council Fire Brigade recommend an expenditure of £136 in providing metal filament lamps for a number of fire stations. The Great Western Railway Co. propose to erect a generating station at Fowey, in Cornwall. A generator panel and accessories for 2,000 amperes is required at Finchley. Loans for considerable amounts in connection with electric supply are recommended by the Finance Committee of the London County Council at Battersea, Hammersmith, Shoreditch, and Stepney. A Local Government Board inquiry has been held at Tonbridge in connection with a loan of £4,000 for electrical purposes. The West Ham Corporation is applying for sanction to borrow £51,600 in connection with the electrical undertaking. For the information of wiring contractors we give particulars of a large number of buildings about to be erected in London and the provinces. (Pages 193-194.)

THE annual meeting of the National Telephone Co. was held on Thursday, when it was stated that the number of exchanges is now 1,513, and the number of exchange and private stations 463,869. The present rate of effective calls is 656,755,000 per annum, and the revenue per telephone station works out at £6 3s. 4d. In London the company has 99,068 stations against 49,690 on the Post Office system. Complaint was made at the meetings of Messrs. Crompton & Co. and the General Electric Co. of the continuation of severe competition in the electrical industry. Mr. Byng, at the latter meeting, said he did not think any permanent improvement would be made until our fiscal policy is altered. The report of the British Thomson-Houston Co. for the year ended March 31st, after deducting debenture and other interest, shows a profit of £28,038. The accounts of the Metropolitan Railway Co. for the half year to June 30th show a profit of £157,006, and the balance available for dividends, after meeting debenture interest, &c., is £18,002. (Pages 195 to 197.)

THE second reading in the House of Commons of the London Electric Power Bills is down to take place to-night, and we are pleased to see that at last the Government intends to make a genuine effort to put the whole question on a sound basis, once and for all. No official opposition is to be offered to any of the Bills, but Mr. WINSTON CHURCHILL, on behalf of the Board of Trade has given notice of a motion in regard to the London & District Electricity Supply Bill that it be an instruction to the Committee to insert a provision conferring purchasing powers upon the London County Council. It will be remembered that this matter was discussed at some length before Lord CROMER'S Committee, and that the promoters of the Bill have no objection to these powers being conferred upon the London County Council. Their reason for asking the House of Lords Committee to leave the matter open, and not to mention specifically any purchasing authority, was purely with a tactical object, for it at once raised the question of opposition from other county councils involved in the scheme on this particular point and created the spectacle of one opponent objecting to the proposals of another opponent of the Bill. Mr. FITZGERALD, K.C., the leader for the Bill, foresaw that this might have the effect of hanging up the Bill for the session. It now appears, however, to be the desire of the Board of Trade that the London County Council should be specifically mentioned in the Bill, and there is also a general feeling that in return for being granted the linking up powers contained in their Bills, the London electric supply companies shall be compelled to fall in with a general scheme for ultimately handing over their undertakings to the London County Council. This principle also involves the borough councils, whether such a general scheme of purchase is to be carried out in 1931, the date at which the borough councils can now purchase the companies' undertakings, or in 1951, the date mentioned in the London & District Bill. For the first time in this controversy the question of severance has been given special prominence, for it is laid down in the Electric Lighting Acts that where only part of a company's undertaking is acquired by a local authority, compensation shall be paid to the company for loss incurred by the severance of that portion of the undertaking. Consequently if a general scheme for the acquisition of all the electric supply undertakings in a defined area in and around the metropolis were given effect to, this question would cease to have importance. It was in consequence of these proposals of the Board of Trade becoming known that Mr. MORTON asked that the debate upon the second reading should be adjourned until the autumn session in order to give the borough councils and others interested time to consider the new position. As will be seen from another column, the Government has shown a further indication of their desire to avoid any delay which will have the effect of postponing a decision on this important matter beyond the present session, and has refused to adjourn the second reading. No doubt there will be a clear exposition of the attitude of the Board of Trade during the debate this evening, because any scheme for the acquisition of electrical undertakings in London and district by a central authority goes beyond the transfer of the present powers of purchase of local authorities. Any such scheme must also include the municipal undertakings, and this has really been the crux of the matter hitherto. It will also be interesting to learn how it is proposed to dispose of the difficulties which must at once arise when, as will be the case here, one county council is given purchasing powers over an undertaking in the area of another county council.

THE most extraordinary amount of popular interest has been taken in the unfortunate troubles which led to the cessation of the service of tramcars equipped on the G. B. surface contact system along the Mile End Road. The report of the Highways Committee on the subject, which is given at some length in another column, is strongly worded, and practically characterises the system as a complete failure. The Committee have not, however, thought fit to give any technical detail whatever as to the actual causes of trouble, such as whether it is mainly due to live studs caused by sticking of the plungers or leakage or other irregularities. In view of the wild remarks of the halfpenny papers, we should have thought an authoritative statement of a more detailed nature would have been very desirable. The first inquiry that everyone interested will make is naturally as to what differences in design are present between the L.C.C. equipment and that giving such excellent results at Lincoln, and a very strong position with regard to this is taken up by Messrs. GRIFFITHS and BEDELL, who state in a circular letter that we are able to publish in full that such modifications as have been made in the designs by the County Council engineers were against their advice and contrary to the results of their experience on the pioneer line. They also point out that the Board of Trade inspection was carried out, and traffic commenced in spite of their representations that the equipment was in an unsatisfactory state. It must be borne in mind that the equipments of the three cars that were run were more or less of a temporary nature, and were hurriedly put into use at a time when a good deal of pressure was being brought to bear as regards an early commencement of the service, and did not represent the final form of the designs of the engineers to the Council. The inventors show their unshaken confidence in the system by offering to make the alterations they consider necessary under heavy guarantees as to the proper working of the system, but the Highways Committee, notwithstanding the faith that Mr. WHITTAKER THOMPSON has always shown in the ultimate success of the system, do not see their way to acceding to the request, and are unwilling to take any further risks in the matter. The only alternative they have to suggest is the conversion of the line to the overhead system, as owing to local conditions the cost of the ordinary conduit would be prohibitive. This solution to the problem is by no means as easy as it looks, and the Stepney Borough Council have again declared their unwillingness to withdraw their veto on the overhead system, and nothing short of special Parliamentary powers can enable the County Council to act against their pronouncement. The situation is one of considerable difficulty, and whether the irregularities of working could have been avoided by differences in the details of design or not, it is much to be regretted that the troubles of the Council's engineers should have been made an excuse for the showing of so much party animosity. In accordance with the procedure of the London County Council, the report of the Highways Committee was not discussed at Tuesday's meeting, but the interesting announcement was made that the G.B. Surface Contact Co. contemplate the institution of legal proceedings in the matter, so that there is every likelihood of the matter being thoroughly investigated apart from party politics.

PARLIAMENTARY INTELLIGENCE

FIRES ON TUBE RAILWAYS.—In the House of Commons, on Wednesday last week, Mr. Weir asked the President of the Board of Trade whether, in view of the risk of suffocation of passengers in the tube railways of London should the wooden sleepers by any accident become ignited, he would communicate with the various companies on the subject. Mr. Churchill replied that the Board of Trade proposed to await the report of the inquiry of Colonel Yorke and Mr. Trotter into the recent fire on the City & South London Railway before considering what action, if any, is necessary with regard to this and kindred matters.

THE "G. B." SURFACE CONTACT SYSTEM.—In the House of Commons, on Wednesday, Sir J. Benn asked the President of the Board of Trade whether his attention had been directed to the accidents in the Mile Road, London, consequent on the installation by the London County Council of a route of electric tramways on the stud system; whether this line was inspected by his Department, and was he aware that the London County Council proposed to extend this system to other parts of London; and whether the Board of Trade could take steps to protect the metropolis from the dangers of such extension. Mr. Churchill replied that he was aware that accidents had occurred on the tramway in question, which was inspected on behalf of the Board of Trade before being opened experimentally for traffic. He had no knowledge, however, of any intention on the part of the London County Council to extend the use of this system to other parts of London, and no such extension could be carried out without the consent of the Board of Trade.

LONDON ELECTRIC POWER BILLS.—In the House of Commons on Monday Mr. A. C. Morton asked whether the Prime Minister would consent to the second reading of the London Electricity Bills being put off till the autumn session, so that the London local authorities might have an opportunity of considering the new proposals of the Board of Trade. Mr. Churchill, the President of the Board of Trade, who replied, said he was advised that it would be fatal to the Bills if the second reading were postponed to the autumn session. The proposal to make the London County Council the purchasing authority was not new, but was considered by the Committee of the other House. Full opportunity would be given for existing purchasing authorities to be heard before the Committee, and ample time would be available for the preparation of their case.

The second reading debate takes place this (Thursday) evening. There are eight motions to reject the London & District Electricity Supply Bill, whilst the President of the Board of Trade will move that it be an instruction to the Committee considering the London and District Supply Bill to insert the name of the London County Council as the purchasing authority. At the same time, it may be pointed out that the Parliamentary Committee of the London County Council does not propose to offer further opposition to any of the Bills. Practically all the opponents to the London and District Electricity Supply Bill in the House of Lords has deposited petitions against the Bill in the House of Commons.

THE NOTTINGHAMSHIRE & DERBYSHIRE TRAMWAYS (No. 2).—This Bill has been reported for third reading by the Unopposed Committee of the House of Lords. The Bill authorises agreements between the Nottinghamshire & Derbyshire Tramway Company and the Nottingham Corporation, under which the latter construct certain tramways (powers for which are in the hands of the company), and also gives the company running powers over some lines in the city of Nottingham.

PROGRESS OF ELECTRICAL BILLS.—Tramway Provisional Order Confirmation Order Bill No. 2 was read a third time and passed in the House of Commons on Thursday.

The Great Northern, Piccadilly & Brompton Railway Bill, the Keighley Corporation Bill, and the Metropolitan Electric Tramways Bill were read a third time in the House of Commons on Monday.

In the House of Lords on Monday the following Bills were read a third time and passed: Central Ireland Electric Power, London United Tramways, and Nottinghamshire & Derbyshire Tramways (No. 2).

The Telegraph Construction Bill was read a second time in the House of Lords on Thursday.

The Macclesfield & District Tramways (Abandonment) Bill was read a third time in the House of Lords on Thursday.

TRAMWAYS TRAFFIC DEPARTMENTS.—In the House of Commons on Thursday, Mr. Steadman asked the President of the Board of Trade if he could state the number of men employed in the traffic departments of the various tramway undertakings in the United Kingdom. Mr. Churchill replied that he had no statistics of the kind referred to.

Radio-telegraphic Convention.—The Governor-General of Monaco, in giving notice of his State's adhesion to the Berlin Wireless Telegraphy Convention, states that there is no wireless installation in the country at present, but that one will be erected as soon as circumstances permit.

Digitized by Google

THE USE OF HARD WOODS FOR CONSTRUCTIONAL PURPOSES

By a Civil Engineer

WITH the development of heavy engineering in connection with electrical undertakings, more particularly in such affairs as the construction of tramways and the electrification of railways, problems pertaining more exclusively to civil engineering have become invested with a certain amount of interest for the electrical engineer. One of the most interesting points in the choice of building material—more particularly at the present time, when iron and steel have reached a somewhat inflated price—is the limit of the possibilities of hard wood in connection with the construction of electrical engineering buildings and appliances. The three sections under which this question should be considered may be scheduled as the question of inflammability, that of resistance to crushing or vibration, and that of adaptability for use in constructional work where iron or similar materials are usually employed.

The prime importance of the first point is evident on considering the stringent conditions to which constructional materials are subjected in connection with electrical engineering work, more particularly at the present time, when the increase of the size of generating units produces a tendency to maintain an electric arc due to short circuit. When this occurs materials used in construction must be of a nature calculated to resist excessive heat, if they are in any way to satisfy the conditions determined by experience and enforced by the Board of Trade. For this reason a large number of central stations and sub-stations are now built with concrete and iron floors on the Hennebique or similar system and the use of wood, more especially in the vicinity of switchboards, is studiously avoided. At the same time, this may be carried somewhat to excess, and a test made upon some karri beams by the British Fire Prevention Committee in 1903 shows that hard wood is capable of withstanding destruction due to heat to a considerable extent. A brick hut, 22 ft. long by 10 ft. wide, was arranged with several lengths of karri timber 2½ in. thick placed so as to form a ceiling, and on the top of these was a load of bricks weighing about seven tons. Coal gas was then turned on from a generator, and in a short time the interior of the hut was red hot, the temperature at the end of two hours reaching close upon 2,000° Fah. At the end of this time it was discovered that in no place had the fire burnt through the wood, and the load of bricks remained undisturbed to the finish. The underpart of the planks, which were in actual contact with the fire, were, of course, considerably charred, but otherwise the woodwork was unharmed. These conditions would seem to indicate that hard wood, more particularly if well selected and polished, could be used fairly extensively for the constructional work of low-tension switchboards. The insulating property of karri and jarrah is fairly high, and the polishing would prevent the absorption of moisture. The argument that charring might occur in case of an arc may be met by the observation that if a slate slab were subjected to the same condition it would crack and fly about in the most objectionable manner. Even if hard woods were not adopted in parts quite so near the electrical contacts as above mentioned, there is no reason why it should not be used for the flooring of electricity stations, as its perfect safety in this connection is demonstrated by the fact that the London County Council's Building (Amendments) Act of 1905 specified jarrah, karri, oak, and teak as fire-resisting timbers for use in doors, staircases, beams, posts, and floorings.

An incidental point in favour of the use of hard woods for the flooring of electricity supply stations is the fact that it affords greater ease of attachment than concrete for machinery laid upon it, where such machinery is liable to be moved from time to time. There is much less risk of holding down bolts slacking back, and it has the advantage that no dust will arise from it during the course of running the station, as would occur in the case of a concrete floor. Instances have been known where sharp gritty dust from concrete flooring has got into the electrical and mechanical portions of running machinery and caused serious damage; indeed, it is a common precaution in newly-built stations to keep almost twice as much lubrication on the wearing parts of the engines, should these be of the open type, on account of the chance of any slight wind storm carrying the grit from the newly-made floor into the bearings.

The second point with regard to the use of hard woods in electrical construction work is the question of strength and durability. In this connection a mass of conflicting tests and opinions is available, but there seems to be no reason to doubt the fact that hard woods (providing questions of cost are favourable) might be used to a very much greater extent than at present. Karri and jarrah, for instance, are not only intrinsically strong, both in tension, shear, crushing, and compression, but they are very well adapted to stand shock or vibration; this is evidenced by the fact that these woods are largely employed, together with teak or oak, in the construction of the wooden fenders which are placed along dock walls in order to catch the shock of any ship striking the constructional work. The intense grinding and tearing action that goes on between the wooden fender and the iron plates of the ship are sufficient evidence of the fact that hard woods are capable of withstanding a considerable amount of rough usage. From a number of tests taken by Mr. W. H. Stanger, M.Inst.C.E., upon hard woods, the following averages were obtained:—

Jarrah will stand approximately 6¾ tons tensile stress per square inch, while karri will take 8¾ tons per square inch. Karri will bear nearly 4 tons compression per square inch in the direction of the grain before a permanent set is noticeable, while the ultimate crushing strength of jarrah is about 4¼ tons.

Comparative tests between various samples of wood made by the Chief of the Testing Department of the Belgium Railways shows that karri, besides having almost twice the strength of pitch pine (Karri, average of four tests, ultimate breaking load 39,583 lb.; pitch pine, average of 3 tests, 20,281 lb. on samples 10·6 in. × 11·8 in. × 23 ft. between supports) gives a fairly satisfactory deflection before breaking, and is hence likely to survive very severe conditions with regard to vibration. For this reason it is excellently applicable to forming foundations, flooring, and beams for electrical generating machinery, more particularly of the turbine type, where a great dead-weight of foundation is not necessary, and the cheapening effect upon the cost of construction is distinctly a point in favour of its use. The competing form of construction in this connection is, of course, the use of constructional steel and ironwork, and while it is undoubtedly true that with standard sections it is a very easy matter to construct girder and trestle work of good strength and rigidity, the cost of maintenance of such ironwork must be taken into consideration, whereas hard wood requires little or no attention after the first labour of putting it

Digitized by Google

together. Iron and steel work needs periodical repainting and examination in order to keep it in good condition, and it should be remembered that in exposed situations where it is likely that severe changes of climate may be felt, iron girder work is apt to become brittle, and its resistance to sudden shock may, under certain conditions, be considerably less than what is anticipated.

The cost of hard wood would, under normal conditions in England, be higher than that of steel, but in outlying situations, where the cost of transport of steel has to be taken into account, hard woods might be used with considerable advantage.

In 1904 the question of the use of hard wood for building purposes arose in Bombay, and the Port Trust Engineer reported that the cost of beams of karri would be rather less than that of rolled steel beams, while teak would be rather more, and a solid timber beam, 12 in. × 16 in. would, in his opinion, make a more fireproof floor than light rolled beams. The writer is also in receipt of information from Messrs. Millers Karri & Jarrah Co., Ltd., that in New York these woods are being used in preference to oak grown in the country, in spite of double freight (from Australia to England and from England to America), import duty and full sale price, for constructional work in connection with the Hudson Companies' Tunnel Railways, and all the London tube railways, except the original "Twopenny Tube," which uses concrete, employ karri, or preferably jarrah, wood for their sleepers.

This brings us more particularly to the question as to its use in constructional work where iron might otherwise be employed. This has been partly considered above, but there are certain points in connection with track and pole line work for electric railways and similar purposes, which might well be emphasised. In track work concrete and iron sleepers are most objectionable on account of the noise produced when trains run over them, and while longitudinal hard wood sleepers might not be a positive cure for "roaring rail" they would, at any rate, do a considerable amount of good in mitigating the evil. In this connection also hard wood might be used more extensively for the heavy longitudinal members of tram-car bodies and similar purposes. It might be used on double-deck cars for the top rail in order to render these more comfortable to passengers in cold weather and to reduce risk of shock in the event of a slight electrical leakage.

That hard wood blocks are a suitable paving in connection with tramway rails is, of course, well known, and the Borough Engineer of Plymouth drew attention in 1903 to the fact that some of the blocks placed along the side of a tramline were slightly grooved at the edge, due to the fact that the rail after seven years' wear was deeply grooved. The effect of this point alone on the life of a wheel is important. For pole lines hard wood has stood a considerable amount of practical testing. In the Cauvery Falls Railway Power Transmission Line, Indian wood poles were first used for the transmission, but under the stringent atmospheric conditions these rotted rapidly, and the introduction of jarrah wood for the poles and arms satisfactorily removed this difficulty.

In all stations where humidity is liable to be a disturbing factor in pole line construction, hard wood would appear to be more useful than iron on account of the excessive maintenance required in scaling and re-painting. *Engineering*, vol. 83, page 5, quotes the case of wood telegraph poles twenty years old, which had only decreased 5 to 7 per cent. in strength, so that provided the æsthetic objections of local authorities can be overcome, wooden poles appear to be the economical solution to the cost of distribution over large areas; and where climatic conditions are unfavourable to the life of wood, the hard wood pole appears to carry the greatest advantage; in addition to which hard woods are from their oily nature possessed of remarkably good insulating properties. In the above notes karri and jarrah have largely been mentioned, inasmuch as they possess the requisite quality of all materials of construction, of hardness and resilience in a considerably marked degree. There is another western Australian hard wood called "Yate," which, perhaps, gives even greater intrinsic properties, but there appear to be commercial difficulties in using yate, so that the claim of karri and jarrah as the hardest commercial woods appears to be amply justified. The only non-Australian wood which possesses anything like their hardness is lignum vitæ, which is in extensive use for the bushing of propeller shafts and similar work. It would therefore seem that further extension of the use of hard woods in electrical engineering undertakings might be made along the lines indicated, more particularly in places abroad removed from direct communication with iron and steel mines, on account of the durability, insulating properties, and non-inflammability of these woods.

COAL CUTTING MACHINES

THE following table, compiled from material in the annual reports of His Majesty's Inspectors of Mines, and showing the proportions of electrical and compressed air coal cutting machinery in use in various districts, is given in the *Iron and Coal Trades Review* :—

District.	No. of machines at work.		Total machines.	Coal cut, tons.
	Electrical.	Compressed air.		
Cardiff	3	14	17	116,484
Durham	76	76	152	1,142,489
E. Scotland	166	91	257	2,628,969
Liverpool and N. Wales	11	118	129	874,865
Manchester and Ireland	11	67	78	258,950
Midlands	81	73	154	1,643,271
Newcastle	40	97	137	899,824
Southern	4	18	22	67,478
Stafford...	17	32	49	416,732
Swansea	6	5	11	49,076
W. Scotland... ...	114	91	205	1,746,049
Yorks. and Lancs.	114	168	282	3,032,837
Totals	643	850	1,493	12,887,054

The total number of machines shows an increase of 360 over the figure for the previous year, which is a larger increase than has taken place in any year.

Taking individually the dozen mine inspection districts into which the country is divided, we find that Yorkshire and Lincolnshire together preserve the pride of place as regards the number of machines employed and the quantity of coal cut by them, there having been an addition of 30 machines in 1907, as compared with 1906, when only five were introduced. Next come the collieries of East Scotland, where much development work is in progress, with 257 machines, or 81 more than last year, while West Scotland has brought its total up to 205, or an increase of 76. Durham and the Midlands are running a close race with 152 and 154 respectively, while the Newcastle district boasts 137, and Liverpool and North Wales 129. Ireland is credited with one machine, and Cardiff with only 17. Swansea has now 11 as against 4 last year; but the Inspector for the district expresses the opinion that it will be many years before machines make much headway there. As for the motive power employed, compressed air is still first favourite, driving 850 machines, while electricity is employed for 643. It is noteworthy, however, that while in the former case the increase on 1906 is 168, in the latter it is no less than 192, showing how rapidly electricity continues to come to the front.

GLASGOW CORPORATION TRAMWAYS ACCOUNTS

THE fourteenth annual report of the Tramways Committee of the Corporation of Glasgow for the year ended May 31st, 1908, has just been issued. During the last twelve months, extensions amounting to one mile of double track have been added to the system, which, including leased lines, now comprises over 89 miles of route. The alterations to the Pinkston power-house buildings in connection with the extension of the switchboard have been completed, and one of the two new 3,000 kw turbo-generators is at present under construction.

The total number of cars in stock is 759. The stock of cars at May 31st, 1907, was 780, the old single-deck cars, numbering 21, having been written down to a nominal figure and taken out of this account. The Committee have decided to equip all the cars with side lifeguards. The average number of cars in use for a 14-hour day was 548, the average number of car miles per day 103·5, and the average speed 7·93 miles per hour.

The working expenses per car mile (including power works cost) amounted to 5·893d., or 55·6 per cent. of the total receipts. The following is an analysis of the working expenses and capital charges:—

ANALYSIS OF EXPENSES PER CAR MILE.

	Year ended May 31, 1907.	Year ended May 31, 1908.
Traffic expenses—	d.	d.
Salaries and wages and bonus ...	2·288	2·328
Cleaning cars and depot expenses...	0·328	0·341
Cleaning, salting, and sanding track	0·051	0·047
Ticket check	0·123	0·127
Uniforms	0·064	0·086
Miscellaneous	0·036	0·037
	2·890	2·966
General expenses—		
Salaries and wages	0·083	0·078
Rent, rates, and taxes	0·550	0·562
Insurance, law, and Parliamentary expenses	0·314	0·357
Miscellaneous	0·076	0·058
	1·023	1·055
Repairs and maintenance—		
Permanent way	0·752	0·662
Electrical equipment of line ...	0·090	0·108
Cars	0·280	0·344
Electrical equipment of cars ...	0·210	0·211
Buildings and miscellaneous ...	0·108	0·093
	1·440	1·418
Power expenses—		
Fuel	0·161	0·203
Oil waste, water and stores ...	0·024	0·025
Salaries and wages	0·108	0·117
Repairs and maintenance	0·076	0·086
Energy purchased	—	0·023
	0·369	0·454
Total costs, excluding capital charges	**5·721**	**5·893**
Rental of leased lines	0·117	0·114
Interest	0·752	0·614
Sinking fund	0·587	0·795
Income tax	0·117	0·109
Balance of Parliamentary expenses written off	0·082	0·033
Payment to "common good" fund...	0·413	0·405
Depreciation and permanent way renewals fund	1·986	2·180
Special depreciation fund	0·531	0·047
Total costs, including capital charges	**10·306**	**10·190**

The increase in the traffic as compared with the previous year can be seen from the following figures:—

	Year ended May 31, 1907.	Year ended May 31, 1908.
Miles open for traffic (single track)...	176·25	179
Car miles run	20,350,367	20,766,722
Passengers carried	224,063,098	226,948,290
Receipts per car mile...	10·465	10·488

Although the working expenses, excluding capital charges, are somewhat larger than those for the previous year, the smaller amount appropriated for the special depreciation fund causes the total costs per car-mile (including capital charges) to be less than for the previous year. During the previous year over one and a half million units of electrical energy were sold to the Corporation electricity department, whereas in the year under consideration, 496,700 units were bought from this department at the rate of 1d. per unit. This accounts for the figure of 0·023d. for energy purchased, which appears in the analysis under "Power expenses." The total working expenses amounted to £509,895, and the receipts from all sources reach the figure of £916,565 (including £6,247 for interest on surplus revenue). Of the balance thus given, £9,861 was required for rental of leased lines (Govan and Paisley districts); interest, sinking fund, and income tax absorbed £53,152, £68,804, and £9,436 respectively, and £2,884 was written off as balance of Parliamentary expenses. £35,000 was contributed to the Glasgow Corporation "common good" fund, £188,603 was transferred to depreciation and permanent way renewals fund, and £4,061 was appropriated for a "special" depreciation fund, so that finally a surplus of £34,869 remained, which was carried to reserve.

The following is an analysis of the net capital expenditure on the undertaking, as at May 31st, 1908, after deducting amounts set aside to meet renewals and depreciation:—

Permanent way	£994,570
Electrical equipment of line	656,449
Land	136,222
Buildings and fixtures	445,891
Power stations and sub-stations	390,668
Cars	263,629
Electrical equipment of cars	189,352
Miscellaneous...	68,795
	£3,145,576

The following table shows the amount of electrical energy generated at the power-station during the year, and also the various losses:—

Units generated in power station—	
(*a*) Alternating current (6,500 volts)	27,595,026
(*b*) Direct current (500 and 100 volts)	1,067,595
Total units generated	28,662,621
Purchased from Electricity Department (6,500 volts)	496,770
Total units dealt with	29,159,391
Used at power station	1,219,128
Total issued from power station to sub-stations	27,940,263
Used in sub-stations, depots, &c.	2,007,373
Total issued to sub-stations for traction load...	25,932,890
Lost in conversion and transmission	2,332,517
Total units issued from sub-station direct-current busbars for traction load	23,600,373

The number of units used per car mile were 1·25. The maximum load on the station was 8,528 kw., giving a load factor of 38·3 per cent. The coal consumed

Digitized by Google

per kilowatt-hour generated was 2·97 lb. The generating costs per unit supplied are analysed in the table below for the year under consideration and the previous year. These figures are calculated on the number of units issued from the power station to the sub-station, exclusive (for the year 1907-8) of the amount supplied by the Electricity Department, namely, on 27,443,493 units.

	Year ended May 31, 1907.	Year ended May 31, 1908.
	d.	d.

ELECTRICAL WORK OF THE PHYSIKALISCH-TECHNISCHE REICHSANSTALT IN 1907

THE following particulars concerning the work of the German Physikalisch-Technische Reichsanstalt during 1907 have been taken from the annual report. In the Standards Department the variations in manganin resistances have been found to be very slight and the "humidity effect" only just perceptible. Resistance coils are now being wound on metallic spools with longitudinal slots to render them somewhat flexible; in this way it is hoped to make any effect due to humidity practically negligible. The size of the grains of mercurous sulphate used in the preparation of standard cells is believed to play an important part in the behaviour of their E.M.F. Further experiments are in progress to discover the cause of the initial variation of the cells. Measurements of the wave-length of electric oscillations can be made with an accuracy within 1 part in 1,000 for long waves (above 1,000 metres), and in the case of shorter wave lengths the accuracy is within 1 per cent. Apparatus is on order by which it is hoped to increase the accuracy of the measurements.

Other experiments have been made with undamped electric oscillations produced after the Poulsen method by means of an arc burning in oxygen, with which arrangement the constancy of the oscillations both in regard to their wave-length and intensity was increased. A lamp was first constructed in which the arc burned between a cooled outer cylinder of copper and the surface of a 20 mm. solid carbon rod. A magnetic field in the direction of the axis of the carbon was produced by a coil through which the lamp current passed. This magnetic field was adjustable in intensity, and as it kept the arc continually rotating it ensured the carbon burning away evenly. With this arrangement it was possible to obtain oscillations of great constancy for a long time. In regard to the analysis of electric vibrations, an A.C. oscillograph was constructed in the previous year on Gehreke's principle; this instrument is based on the property of the cathodic glow-light to cover a surface proportional to the current density. By using a rapidly rotating brilliant concave mirror, it was feasible to analyse electric vibrations down to 500 metres wave-length with the aid of this oscillograph. The damping and form of the vibrations, the vibrations in connected systems, the influence of the spark gap and undamped Poulsen vibrations could be demonstrated photographically or observed direct by the eye.

During the year a number of intermittent tests on dry cells (in these tests the circuit remained closed three minutes in each quarter of an hour, and the cells were discharged to the terminal voltage of 0·8 volt) were made in accordance with the procedure of the Testing Bureau of the Imperial Telegraphs, Berlin, at the desire of manufacturers. Moreover, for the information of the Reichsanstalt itself, five cells were discharged continuously through a resistance of 10 ohms, and five others intermittently through the same resistance, both sets of tests being made at terminal voltages of 0·8, 0·6, and 0·4 downwards. The tests showed that the current yielded by both sets of cells was 40 per cent., 10 per cent., and 5 per cent. greater with intermittent discharge than with continuous discharge, the discharge voltages being 0·8, 0·6, and 0·4 volts respectively. Researches were carried out bearing on the question of the influence of the chemical composition and thermal treatment on the magnetic properties of iron alloys and on the regularity of rolled material used in dynamo construction.

The ordinary routine tests were made on instruments, insulating materials, plant accessories, &c. The electric lamps tests were as follows:—460 carbon filament glow lamps (64 of these for life); 183 metallic filament lamps (Osram, Tungsten, and Osmin lamps), 106 of these being tested for life; 20 Nernst lamp filaments; six arc lamps with carbon electrodes; two mercury arc lamps with glass vessel. Tests were also made on one photometer head for equality and contrast. In regard to the glow lamps tested, a series of five 220-volt carbon filament lamps may be mentioned. These decreased 20 per cent. from their original candle-power value during an average life of 920 hours. The current consumption per one Hefner candle of mean c.p. vertical to the axis of the lamp rose from 3·8 to 4·9 watts.

For the various laboratories of the Reichsanstalt itself, 11 single resistances and four sets were tested, as well as four metal bars of copper and aluminium; silver and nickel wires were also tested for specific resistance and temperature coefficient. A number of Weston cells made by the European Weston Co. were also tested. In the Magnetic Laboratory a total of 129 tests were made on non-magnetic material (nickel-steel), cast-steel, cast-iron, magnet steel in bar form, horse-shoe magnets, dynamo sheets, &c. During the year thirteen systems of meters were tested as to type, and seven systems were submitted for verification. A number of the researches undertaken by the institution were not concluded when the report was compiled, and are being continued this year.

Institution of Mechanical Engineers.—The Summer meeting of the Institution of Mechanical Engineers was held at Bristol on Tuesday and Wednesday. There were no Papers of electrical interest.

£10,000 Telephone Claim.—A counterclaim by Col. Edward Gouraud, of Marine Parade, Brighton, for £10,000 damages against the National Telephone Co., was heard in the Brighton County Court last week. The counterclaim, which was made in an action by the National Telephone Co., against Col. Gouraud for £5 5s., proportion of telephone rentals, Post Office fees, and removal charges, was on the following grounds:—(*a*) neglect of duty; (*b*) breach of contract; (*c*) pecuniary loss; (*d*) injury to health; (*e*) prolonging an already long and critical illness; (*f*) increasing expense of doctors; (*g*) unwarrantable and illegal disconnection of exchange service; and (*h*) making statements prejudicial to the credit and honour of the defendant. The Colonel complained that his telephone service was practically useless, and that the instruments were obsolete. He had given orders for the instruments to be thrown out, but his instructions had not been obeyed. The Judge gave verdict for the company, and struck out the counterclaim.

Tantalum Lamps on Alternating Circuits.—Some sketches showing the peculiar effect of alternating currents on tantalum filaments as viewed in the microscope are published in the *Electrical World* (New York). The tests in question are by Mr. M. D. Abbot, of Nebraska, and include observations on the effect of continuous and intermittent, as well as alternating, currents. The effects are very similar to those shown in the micro-photographs given in ELECTRICAL ENGINEERING, Vol. I., pages 109 and 153. Observations were also made of the alteration of tensile strength with life. The lamps used in these tests were of American make, rated at 20 c.p. and 110 volts. The measured diameter of the filament was 0·0017 in., with a tensile strength as obtained from tests made on two samples of 225,000 lb. per square inch, being thus much stronger than steel. The colour was steel grey, with a metallic lustre. The lamps were suspended from coil springs placed between two supports, and connected, two in series, to 220-volt mains. The tensile strength of one of the filaments tested under direct current was found to be greatly reduced at the end of the run of 148 hours, and varied from 30,000 lb. to 60,000 lb. per square inch. The colour had changed from a silver grey to a dull black, and slight depressions of creases were noticeable. The filament became brittle, but remained strong enough to withstand a moderate jar or shock. The colour after the run was very glossy black. The results of the tests on alternating current show the characteristic breaking up into short lengths. The effects of intermittent currents appear very similar, except that the colour of the filament after the run is described is a dull black instead of a glossy black.

THE "G.B." SURFACE CONTACT SYSTEM

THE Highways Committee of the London County Council has presented a report dealing with the withdrawal of the cars upon the "G.B." surface contact system from Aldgate to Bow. The report recalls the fact that the Council on July 23rd, 1907, decided to reconstruct the horse tramways between Commercial Street, Aldgate, and Bow Bridge, via Whitechapel High Street, Mile End Road, and Bow Road, on the "G.B." surface contact system of electric traction. On the same date the Council approved an estimate of £72,210 for the execution of the work, including the payment of a sum of £500 a mile single line as royalties, if the Council did not decide to discontinue the use of the system. On July 7th, 1908, the reconstruction of this length of tramway had been completed and the lines inspected on behalf of the Board of Trade, and the Board granted a certificate for the working of the line for a period of six months. Electric car services were instituted on the tramways on June 25th, 1908. At the outset it was only found practicable to place three cars on the tramways. The report continues :—

We now regret to have to report that the results obtained from the working of the lines are such as to show that it will not be practicable to continue the use of the system consistently with the safety of the public using the roads, and the efficient working of the tramways under the circumstances prevailing on this route. Arrangements have been made, therefore, pending our submission of the facts to the Council, for the electric cars to be withdrawn. The agreement which was entered into with the G.B. Surface Contact Co. with reference to the matter provided that, if at any time after the opening of the tramways the Council decided to remove or cease to use the system, or to substitute some other system, the company should not be in a position to claim the royalty which would otherwise be due to it under the agreement. Having given the most anxious consideration to the matter, we have reluctantly arrived at the conclusion that it is our duty to advise the Council in all the circumstances to discontinue the use of the system on these tramways. We informed the G.B. Surface Contact Co. of our decision to withdraw the electric cars, and we have since received from the company a letter making certain suggestions with a view to the running of the electric cars and the working of the tramways being continued on the surface contact system of electric traction. After carefully considering the matter, however, we do not see our way to recommend the Council to take any action with regard to these proposals, and the company will be informed accordingly.

We have very carefully considered what action should be taken by the Council in the event of it adopting our recommendation in the matter. It will be remembered that it was originally intended to construct the portion of the route between the county boundary at Bow Bridge and Cambridge Road (four miles single lines) for overhead traction, and the remainder of the route, from Cambridge Road to Aldgate (one and a half miles single line) on the conduit system. This decision was mainly arrived at because of the engineering difficulties which presented themselves to the adoption of the conduit system throughout, owing to the small amount of cover between the station roofs of the Whitechapel and Bow Railway, which runs underneath the route of the Aldgate to Bow lines, and the surface of the carriageway, the officers having reported that exceptionally heavy expenditure, would have to be incurred if the conduit system were installed at this section. Moreover, such a step would entail a serious hardship upon the residents and tradespeople in the roads traversed by the tramways, owing to the necessity for again taking up the lines, and the consequent dislocation of traffic. We have considered what course can be best adopted both to minimise the loss resulting from the termination of the experiment and to secure with as little delay as possible the extension to this important route of the advantages of electric traction. As the result we have decided to suggest to the Council that steps should be taken to equip the lines for the overhead trolley system of electric traction.

The trackwork and cables will serve, almost without alteration, for the working of the lines for overhead traction, and practically the only additional works necessary will be the provision of the overhead equipment, posts, and trolley wires. This work would only occupy a very short time, and would interfere but little with the use of the carriageway for general traffic; moreover, the tramway service could be maintained in the meantime with horse cars. Through services were originally run on this route from Aldgate to Stratford. After the electrification, however, by the West Ham Corporation, on the overhead system, of its lines up to the county boundary at Bow Bridge, the Council's cars were stopped at that point, and passengers desiring to travel from London to Stratford, and *vice versa*, have now to change cars at the boundary. In addition to the lines of the West Ham Corporation, the tramways of the Leyton Urban District Council are worked on the overhead system. These two undertakings are connected with each other, and together comprise a considerable mileage. Other lines outside London in close association with these systems are also constructed and working for overhead traction. These facts appear to us to furnish an additional reason of considerable weight for adopting the course we recommend, as the running of through cars, if practicable, in close connection with, or over these outside lines, would be of great advantage to the large number of persons who wish to travel between the several districts affected. In this connection we may add that when it was proposed to enter into the arrangements referred to above with the West Ham Corporation for them to work the tramways between Bow Bridge and Coburn Road as part of their system, and for the Council to reconstruct that section for overhead traction, the cars for this route were equipped for running in this manner, and the only work which remains to be done to fit the cars for immediate service, is the fixing of the trolley bases and booms. The approximate cost of the trackwork for G.B. surface contact system has been £62,500, and it is calculated that the additional expenditure necessary to adapt lines for overhead traction would be £6,000 for overhead work, &c. (including car equipment), and £2,000 for reinstatement of road surface, &c.

The committee further remark that it is difficult to state with accuracy the additional expenditure which would be necessary if the conduit system were now installed, but from such information as is available at present, they are informed that this would certainly be not less than from £60,000 to £70,000 for roadwork and platelaying alone, and would probably exceed this amount, while the disturbance of the road surface would be necessitated a second time.

The committee express the hope that on consideration of all the facts the two borough councils concerned will see their way to co-operate with the Council in carrying out the arrangements suggested.

In connection with the above the "G.B." Surface Contact Co. had sent the following communication to the members of the London County Council :—

We see from the reports of the Council's meeting held on Tuesday last, that it was decided to abandon the surface contact system on the above route. You will readily recognise that this decision greatly prejudices us as the owners of the patents of the G.B. system. This system has been working at Lincoln since November 23rd, 1905, at a less cost than most overhead systems in this country, and has given entire satisfaction to the Corporation, its officials, and the public, without a single instance of any man or beast having had a shock. The extraordinary contrast between these results and the deplorable state of affairs in the Bow Road is too great to be explained away, by a casual reference to London traffic and London mud, neither of which is the real cause of failure. We therefore think it right in the interests of everyone to lay before you the facts which have led up to the present situation. When the adoption of the system was first under consideration, we were asked to quote for the supply and complete construction of lines equipped with our system, and we accordingly submitted a tender. We were later told that a monetary guarantee must be given equal to the cost of the electrical equipment of the track. This sum was to be retained by the Council for one year, and was only to be paid to us if they were satisfied with the working of the system, and we accepted this proposal. The Council's officials, however, were unwilling to approve the contractors for the road work nominated by us, and the contractors nominated by the officials refused to carry out the work on the basis of the guarantee above-mentioned as required by the Council. As a result of this deadlock, the Council proposed that we should grant a licence, to which course we agreed, and quoted a sum per mile for patent royalties and technical advice during construction. The Council stated that such technical advice was not required, as their technical staff was fully competent to design and superintend the laying of the system, and we therefore agreed to accept a considerably lower sum per mile for royalty. The terms of the licence granted to the Council expressly stipulated our right to reject all material and workmanship to which we could take reasonable objection. Such reasonable objection has been repeatedly made by us in writing to the Council's officials, and so seriously did we regard the deviations that on May 30th, 1908, we wrote, through our solicitors, to the Council that we strongly objected to the Board of Trade inspection being held until our requirements had been complied with. This warning was disregarded with the results that we knew to be inevitable. We now emphaticaly affirm that there is no condition prevailing in the Bow Road which militates against the perfectly satisfactory and safe working of the system, provided that the equipment both in the road and on the cars is properly made and fixed. Without proper manufacture and fixing, tramway apparatus, whether on the G.B. surface contact system or any other, overhead or otherwise, must inevitably cause trouble and danger. So entire is our confidence in the system when properly laid and equipped that we have written to the Clerk to the Council as follows :—

"We learn to-day that your Council have decided to abandon their experiments on the above tramway route. We do not recognise this as an unfavourable verdict on the "G.B." system

Digitized by Google

of electric traction, for the reason that the above tramways are not in accordance with our designs, which fact we have repeatedly pointed out. Our confidence in the ability of our system to deal successfully with London conditions leads us to make you the following offer. We will agree at our own expense to put the electrical equipment of the track in an efficient state and maintain the same in that state for a period of twelve months, provided that the Council will equip the cars in accordance with our designs. The supervision of which equipment we will also agree to undertake at our own cost. If at the end of twelve months the Council continue to use the system, but not otherwise, they shall repay us the sums of money we shall have thereby expended, but in no case to exceed £2,500. This offer is, of course, made without prejudice to our rights should the Council not see their way to accept it, but because we have been very materially injured by the course that events have taken, we hope that the Council will, in common fairness, give it favourable consideration."

In conclusion, we fully recognise that a prevalence of live studs constitutes, occasionally a danger and always an extreme inconvenience which would make the system impossible if such a state of things persisted. There has been no possibility of avoiding live studs with the apparatus in the absolutely unsatisfactory condition which prevailed during the short period during which cars were running. That unsatisfactory conditon is due to the total disregard of the advice and instructions from us, the patentees of the system. We therefore trust you will support the suggestion contained in our letter set out above. If we fail to put the system in order we lose the money we expend in correcting the existing defects. If we succeed the ratepayers of London save a sum which has been variously estimated at sums up to £50,000.

Notice of a motion has been given that when the report comes on for consideration, the Highways Committee should prepare an estimate of the cost of reconstructing the lines upon the conduit system.

An interesting sequel to the above report is a report by the Works Committee of the Stepney Borough Council, in which the Borough Council is recommended to decline to give its consent to the use of the overhead system. It is argued that the conduit system is quite feasible, and that expert evidence can be called to this effect.

THE ELECTRIFICATION OF THE SWEDISH STATE RAILWAYS

Results of Experimental Work

THE experiments in connection with the proposed electrification of the main line railways of Sweden, which have been carried out in the neighbourhood of Stockholm by the State Railway Authorities, were concluded in the early part of the year, and the results of these experiments are embodied in a report by the Chief Engineer, Herr R. Dahlander. The railway authorities have laid the report before the Swedish Parliament, and have expressed their intention of submitting the results of their calculations, with regard to the economy to be obtained by substituting electric traction for steam traction, at the end of this year, together with proposals for commencing the work of electrification on a large scale. The advantages of the single-phase system over the three-phase system with respect to the overhead equipment in particular, were considered sufficient to warrant experiments being carried out with the single-phase system only. Under the conditions prevailing in Sweden the cost of the overhead equipment must play an important part in deciding the system, and it was estimated that a 10,000 or 15,000-volt single-phase system would cost less than a 3,000- or 5,000-volt three-phase system.

Various methods of suspending the contact wire were tried, the most satisfactory being apparently the simple method of fixing the contact wire direct on to a swinging bracket without either suspension or cross wires. It was found necessary, even with catenary suspension, to put the contact wire under a certain amount of tension to ensure satisfactory current collection, and owing to the wide variations in temperature the method adopted on the Hamburg-Altona line of putting the wire under a constant tension by means of a hanging weight was resorted to. A constant tension of about 8 kg. per sq. mm. was employed. The well-known Oerlikon method of suspension was also used on one portion of the line. For section insulation the arrangement of parallel or crossed wires with air insulation was found to be more satisfactory than porcelain section insulators, partly on account of the weight of the latter, but chiefly due to the reduction of the insulating property of the porcelain by smoke and dirt. The brown porcelain insulators were provided with iron pins which were cemented into the insulator with a cement composed of 15 to 17 per cent. water-free glycerine and 83 to 85 per cent. litharge. It was noticed that insulators in contact with the live wires kept themselves free from soot, which was thickly deposited on other insulators. The current collector used in the Oerlikon system was found to wear quickly in spite of the low pressure of 0·7 kg., and this system was considered dangerous for use in stations as the contact wire must be suspended only just above the locomotive in the centre of the track when in stations. As the speed of the trains was limited, on account of the nature of the track, to 70 km. per hour, no experiments at high speeds could be carried out.

Extensive investigations were made in connection with the use of the rails as a return conductor. These showed that a large portion of the current was carried by the earth, this amounting, in some cases when the earth was moist, to as much as 70 to 80 per cent. A difference of phase existed between earth and rail currents, the measured power factor for the rails being in a few cases as low as 0·3. An attempt to increase the earth-current, by means of artificially earthing the rails, failed completely. A number of tests showed that at 25 cycles with a rail weighing 49·5 kg. per m., the rail resistance without copper-bonding, amounted to 0·1 to 0·2 ohm per kilometer of line, the resistance varying with the moisture of the ground. The reactance per kilometer was found to be expressed by the following empirical formula :—

$$\text{Reactance per km.} = 0{\cdot}12 + 4\pi f 10^{-4} \ln\left(\frac{d}{n}\right).$$

where f is the frequency of the current, d the distance between contact wire and rails, and n the distance between the rails. The telegraph and telephone lines adjacent to the track were not seriously affected, chiefly owing to the short length of track. In one case, however, a particularly well insulated telephone line was charged to a potential of 5,000 volts when using a contact-wire pressure of 20,000 volts. This static charge was easily avoided by connecting discharging coils between the lines and earth.

The rolling-stock used for the experiments consisted of a 300 h.p. Westinghouse locomotive, a 300 h.p. Siemens-Schuckertwerke locomotive, two motor-cars each of 230 h.p. supplied by the Allgemeine Elektricitäts Ges., and two trailers. Each locomotive or motor-car has run more than 10,000 km. in the course of the experiments, and the electrical equipment has given every satisfaction. No trouble was experienced with the commutators of the single-phase motors. The forced lubrication of the A.E.G. motors effected a considerable saving in oil. It was conclusively proved that forced ventilation was very effectual in increasing the capacity of the motors and keeping the temperature low. The cable method of leading in the high-tension current was found unsatisfactory at high pressures, and a bare wire passing through the open window or through a porcelain collar was resorted to. The energy consumption varied between 13·9 watt-hours per ton kilometer for a 265 ton train and a speed of 51·4 km. per hour to 19·8 watt-hours per ton kilometer for a 144·5 ton train and a speed of 48·2 km. per hour. These values may be taken as values for a level track, as the short up-gradients on the experimental track were compensated for by corresponding short down-gradients. The momentum gained on the latter served in most cases to overcome the extra resistance due to the former. Experiments were also made in order to determine the relative costs of electric and steam car-heating. The consumption of an electrically-heated passenger car was found to be from 0·2 to 0·3 kw. per degree centigrade difference between inner and outer temperatures. In order to compete with steam heating, the price of electrical energy would have to be at most 0·5 pence per unit. With regard to the most favourable frequency of the single-phase current, the opinion is expressed in the report that a lower frequency than 25 cycles would have more disadvantages than advantages, even considering the possible better working of the motors. The frequency for which the plant was designed, namely, 25 cycles, would seem to be the best.

In conclusion, the report states that the experiments have shown that the single-phase system can be considered as the simplest, cheapest, and most satisfactory system for main line working, and that there is little chance of a better system being devised in the near future. The immediate commencement of the electrical equipment of the main lines and the utilisation of the country's water-power for supplying the energy are recommended. The track on which the experiments were made comprised a 6 km. stretch between Tomteboda and Värtan, and a 7 km. stretch between Stockholm and Järfva. The electric trains have now been temporarily replaced by steam-driven trains, which will continue the service until electrical energy can be obtained from a water-power station. During the experiments current was supplied from a steam-driven power-station. The electrical equipment of the track between Järfva and Värtan is, however, kept ready for use for demonstration purposes. At present the authorities are engaged with the design of the equipment for the main lines.

TRAMWAYS AND LIGHT RAILWAYS ASSOCIATION

Adjourned Discussion to Prof. Carus-Wilson's Lecture on Rail Corrugation

ON Friday last a meeting of the Tramways and Light Railways Association was held for the purpose of further discussing the lecture on "Rail Corrugation," delivered at the last meeting of the Annual Congress on Friday, July 10th, by Prof. C. A. Carus-Wilson. An abstract of the lecture and of the ensuing discussion was given on page 107 of ELECTRICAL ENGINEERING for July 16th. It will be remembered that the lecturer stated that in his opinion corrugation was due primarily to the wheels running on unequal diameters, this causing skidding of the smaller wheel. This skidding, if grit was present on the rail, became intermittent, the period between the skids depending on the limiting twist of the axle.

At the meeting on Friday last the chair was taken by Mr. STEPHEN SELLON.

MR. H. M. SAYERS, who opened the discussion, referred to the Paper on "Rail Corrugation" read before the Institution of Electrical Engineers in March, 1907, by Mr. J. A. Panton. The author of that Paper had concluded that corrugation was caused by defective rolling-stock, and particularly by flange action as the result of skewed axles. In the discussion to that Paper (see ELECTRICAL ENGINEERING, Vol. I., p. 549), Prof. Carus-Wilson had shown himself rather sceptical of these conclusions, and had pointed out that Mr. Panton had not traced the connection between flange action and corrugation. Now, however, the professor had come to very much the same conclusions himself, but had gone one better in that he had given them a definite cause for rail corrugation. Continuing, Mr. Sayers said that he would like to remind the Association that the influence of the torsional vibration of the axle had previously been considered by Mr. T. W. Arnall, Surveyor to the City of Birmingham, in an article published in the *Tramway and Railway World* in 1906. With regard to the alternate skid and roll, suggested by the lecturer as being the cause of corrugation, he thought that alternate *slip* and roll would have the same effect. This latter would take place when the cars were accelerating, and particularly when the motor connections were being changed from series to parallel. On moving the controller to the next higher speed notch, or, say, two or three notches without pausing, the armature torque might suddenly exceed the adhesion value, and the wheel would slip and the motor speed up until the motor couple fell again below the value of the resistance couple due to the sliding friction. In this way, alternate slipping and rolling would be produced. That there might be such a connection between the characteristics of the series motor and rail corrugation had been pointed out recently by M. Lassalle, of Liége (see ELECTRICAL ENGINEERING, July 23rd, page 132). He hoped that Prof. Carus-Wilson would give his views on this point in his reply to the discussion. Alternate skidding and rolling might also take place during braking. There were two points not quite clear to him, and those were: (1) Why was sand a necessary accomplice, and (2) How was it possible that successive cars could produce a combined action on the rails? Some periodic photographs were being taken in London of certain marked portions of corrugated rail, and these, he hoped, would help to solve the problem. In conclusion, he would like to point out that there was not only a grinding action, as evidenced by the hollows, but there was also a cold rolling effect, as the high parts of the rail were rolled up and out into the groove.

MR. J. R. SALTER (Lancashire United Tramways, Ltd.) thought that the chances were very remote that the four conditions mentioned by the lecturer would exist simultaneously. He suggested that the skidding of the wheels in the case of the car experimented with at Croydon was due to the corrugated rails rather than the corrugations due to the skidding. To the many suggested causes for corrugation, he would like to add another, and that was the possible effect of the magnetism of the iron rails due to the unequal distribution of current in the rails. Magnetisation of iron produced a molecular change and an extension in length, and these might have some influence. Owing to the inconsistency in the pitch and the appearance of corrugations, he thought it was necessary to look somewhat further for the cause of corrugation than had been done at present.

MR. J. S. WARNER emphasised the fact that tramway conditions were different to ordinary railway conditions on account of the absence of the check in the latter case. With regard to the oscillations of the wheels, which, the lecturer had shown occurred under certain conditions, he could understand that such oscillations of the wheel on the "free" side might take place, but thought that the friction against the check would prevent the other wheel from oscillating. In any case, he thought the oscillations would be considerably damped by the action of the weight on the wheels. Of the four conditions given by the lecturer as being necessary for the production of corrugations, he thought that one only might be avoided, namely, the presence of a bad wheel section causing check-cutting. To prevent such excessive and irregular wear of the wheels, it was necessary to ensure a uniform flange pressure on either rail which should not become excessive even on an irregular track. The ordinary parallel-axle track did not allow of such uniform pressure, but if a truck construction, permitting of relative angular movement of the two axles (such as the Warner flexible four-wheel truck described in ELECTRICAL ENGINEERING, Vol. III., page 88) were adopted, it would be quite possible. Indeed, the flange pressure and wear was so much reduced with such an arrangement that only half the standard thickness of flange was really necessary.

MR. STEPHEN SELLON said that the tyre section shown in Fig. 2 of Prof. Carus-Wilson's Paper (see ELECTRICAL ENGINEERING, July 16th, page 107) represented an impossible state of affairs. Although it might be possible for a tyre to get in that condition, it would be scrapped long before it could reach that state on a well-managed line. The lecturer had said that the check-cutting which would occur with such a tyre section would produce the alternate skid and roll and the consequent corrugation on the other rail, but he would like to point out that before such check-cutting could take place, the flange of the outer wheel would be grinding on the head of the other rail, and surely that also would produce corrugation. The tyre and the rail section shown by the lecturer were reproduced in Fig. 2 (see below), and to that he had added a rough drawing of the other rail and the other tyre in order to show that before check-cutting could take place, the flange of the other wheel must have ground away a considerable amount of the head of the other rail. Thus Fig. 1 represented the condition of the rail and tyre of the left-hand wheel if

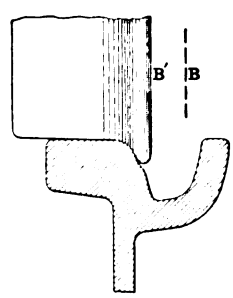

FIG. 1.—LEFT-HAND WHEEL.

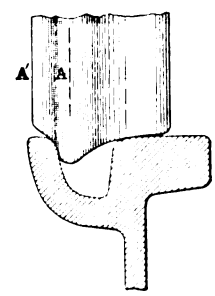

FIG. 2.—RIGHT-HAND WHEEL.

the check-cutting always took place on the right-hand wheel. He, as well as Mr. Sayers, did not quite see why successive cars should act synchronously in producing the corrugations, although running at different speeds. With regard to the ¼-in. clearance between flange and check for a new tyre, he thought it was nearer 1 in. As he had often said, corrugation was due, in his opinion, to the use of rigid road-beds, particularly to the extremely rigid bed laid down by municipal authorities. There had been many examples of steam tramcar lines on which the conditions mentioned by the lecturer existed; the same wear of the check had been noticed, but there had been no corrugation. He had known of curves on which one rail only was a grooved rail, the wheel running on the flat rail on its flange, and yet there was no corrugation. In his opinion it was not essential that the two wheels should be of unequal diameter in order that a torsional effect should be produced. The friction and grinding would produce this effect with equal diameters.

MR. JOHN WELLING (Track Superintendent, L.C.C. Tram-

Digitized by Google

ways) announced that Mr. Ireland (Rolling Stock Superintendent, L.C.C. Tramways) had intended to contribute some remarks concerning the coning of wheel-tyres and rails, but as he was unable to be present, he would send in his remarks as a written communication. With respect to the occurrence of corrugations on rails other than electric tramway rails, he (Mr. Welling) had investigated some corrugations which appeared on the Brixton Cable Tramway lines in 1897. The pitch of the corrugations was smaller than that usual on the present lines, but this was well accounted for, according to Prof. Carus-Wilson's theory, by the fact that the speed was only eight miles per hour. The corrugations occurred chiefly on curves.

Prof. C. A. CARUS-WILSON, in reply to Mr. Darymple's remarks (see report of discussion at the Franco-British Exhibition meeting, ELECTRICAL ENGINEERING, July 16th, page 107), said that before a remedy could be found for corrugation, it was necessary that the causes should be made clear. He thought it would be rather rash to adopt Mr. Gibson's proposal and fit all cars with differential drive. It would be advisable to know more about the matter before going to such an expense. With respect to his attitude in the discussion to Mr. Panton's Paper referred to by Mr. Sayers, he then only repudiated the statement that skewed axles were the one and only cause of corrugation. The same cutting of the tyre could take place with an absolutely square truck, and eventually cause corrugation. In answer to Mr. Sayers' question about the necessity of the presence of sand on the rail, he could only repeat his own view that sand became ingrained into the surface of the rail, thus causing a considerable increase in the coefficient of friction between wheel and rail. When this surface was cut through by the wheel, the coefficient dropped suddenly; it was not the drop due to a change from static to rolling friction, but that due to the nature of the surface. Sand lying on the rail had no effect; it was the particles of grit which had been worked into the surface of the rail. With regard to the synchronous action of successive cars, he thought that was accounted for by the fact that an axle in a state of torsional stress would tend to recover itself at the first hollow it came to, and that would tend to cause the wheels to oscillate synchronously with the existing corrugations. To show how the oscillations were governed by irregularities of the rail surface, he had made the following experiment: A portion of corrugated rail was ground smooth, and slanting chisel marks made on the surface at regular intervals. The cuts became filled with grit, and this so increased the friction that the wheels would not slip or skid when in contact with the cuts, but only during the period between the cuts. In this way the pitch of the corrugations was determined by the chisel cuts. In reply to Mr. Salter, Prof. Carus-Wilson pointed out that the conditions mentioned were all normal conditions, and that consequently the chances of their existing simultaneously were by no means so remote. The molecular changes in iron, consequent upon magnetisation, were so infinitesimal that they could, in his opinion, have no influence. The damping effect of the weight on the wheels, mentioned by Mr. Warner, was certainly present. The weight on the wheels determined the rate of skidding, but did not prevent the rhythmic oscillations. A thick flange could not be avoided unless equal wear on both sides of the truck was ensured. In reply to Mr. Sellon, Prof. Carus-Wilson stated that the tyre and rail sections illustrated in Fig. 2 were drawn from an actual case. With regard to Mr. Sellon's suggestion that grinding between the throat of the flange and the head of the one rail would occur before check-cutting on the other rail, he fully agreed that that must be so, but pointed out that when the side pressure is thus taken by the throat of the flange bearing against the head of the rail, the line of contact is only slightly below the tread of the wheel, and under those conditions the skid is small, not exceeding 1 or 1½ per cent. This small skid would be insufficient to produce the intermittent skid caused by the 3 or 4 per cent. or more skidding consequent upon the check-cutting action. In answer to the question as to the effect of speed, he thought that, if the speeds of successive cars were very different, there would be no corrugation. In reply to Mr. Sellon's statement about steam tram-lines, he had known cases in which corrugation had occurred, but it had never been serious. As to the curves with flat rails, he could not explain the absence of corrugation without knowing all the conditions.

In a written communication, Mr. J. A. PANTON stated that on a certain curve he knew of, the head of the outer rail was half cut away, and yet there were no signs of corrugation. He suggested that wheels and axles should be rigidly fixed in their correct positions, so as to prevent askew running. He did not think that the presence of grit was essential, as corrugations were appearing on the rails of the Underground District Railway, which were highly polished.

REVIEWS OF BOOKS

Lead Refining by Electrolysis. By A. G. Betts. 383 pp. 5½ in. by 9 in. 74 illustrations. (London: Chapman & Hall.) 17s. net.

Only a few years ago it would have been out of the question to write a book of 394 pages upon the subject of the electrolytic refining of lead, for the very good reason that there was no such process. It has been known for a great number of years that lead can be deposited from both acid and alkaline solutions in the metallic condition, but the deposits obtained were of a leafy and crystalline structure, and refused to adhere to the cathode in a dense and coherent form. Therefore all processes which had been tried in the laboratory were found to be unsuccessful for the production of lead upon a commercial scale. Among them may be mentioned Keith's process, developed as early as 1878, in which an electrolyte containing sodium acetate and lead sulphate was employed. The anodes were wrapped in muslin in order to hold back the slimes and thus prevent them from falling to the bottom of the bath and contaminating the lead crystals which fell from the cathode.

A plant of sufficient size to deal with three tons of lead was actually fitted up at Rome, New York. Then there was the process of Ashcroft and Borchers, in which a fused electrolyte was employed. The only really satisfactory commercial project which has been successful upon a commercial scale is that of Anson G. Betts, the author of the book, and, as might be expected, the bulk of the work is devoted to this process. There is not the least doubt but that this work will be of the greatest value to all who wish to read up about electrolytic lead refining or wish to experiment commercially; though, of course, one has to bear in mind that all the methods are covered by patents.

Betts, in his original experiments, studied the known methods of deposition, and found, as others had done, that it was not practicable upon a large scale to produce deposits of any thickness. He then tried various salts of lead and inorganic acids and lead and organic acids. But except in the case of certain organic complexes, the results were not satisfactory. On further experimenting, he found that the addition of one part of gelatine to 5,000 parts of a solution of lead fluosilicate yielded surprisingly fine adherent and compact deposits of lead, which had practically the same specific gravity as ordinary fine lead. Gelatine, however, is not of value with all acids; for example, in acetate solutions it appears to have no effective working.

To go right through the book and pick out all its important facts would exceed the space at our disposal; we will, therefore, only draw attention to a few points picked out haphazard. Thus an interesting section is devoted to refinery construction, operation, and refining costs. Useful blocks are given showing the anodes as cast in the anode mould, the arrangement of the baths, and of the electrodes in the baths. The first appendix includes some interesting photographic blocks of the plant at Trail, British Columbia, and the third appendix deals with the treatment of lead refining slime with ferric fluosilicate and hydrofluoric acid.

The book is to be most heartily recommended to all who are interested in electrochemical progress, particularly, of course, any who are interested in lead refining.

Die Revision elektrischer Starkstromanlagen. By Paul Stern 251 pp. 4½ in. by 6½ in. Eight illustrations. (Hanover: Dr. Max Jänecke.) 3.60 marks.

THIS book is intended for the use of insurance, police, factory, and other inspectors, whose work includes the examination of electrical plant and installations with respect to safety, economy, and reliability of working. A general review of the various kinds of inspection, and a list of the most important public and private institutions, followed by a general description of the method to be employed in making an inspection and drawing up a report, are given in the first part of the book. The second part deals with accidents due to electrical causes, and particularly the effect of electric shock on the human body. Statistics of accidents in Germany and Switzerland are given, as well as instructions for first aid. Part three gives particulars of the various sorts of disturbances or damage which can be caused by electrical installations, and fires traceable to the effect of the electric current are dealt with very thoroughly. The remaining section of the book contains a list of the various laws and regulations holding in Germany, and finally a very complete collection of abstracts and extracts from the more important of these. This section occupies over half the number of pages of the book, and should be of great use to inspectors practising in Germany, although, of course, of less value to the English reader.

THE NATIONAL TELEPHONE CO.'S REPAIR FACTORY

ON the occasion of a recent visit to Nottingham we were courteously invited to inspect the repair factory of the National Telephone Co. in that city, and

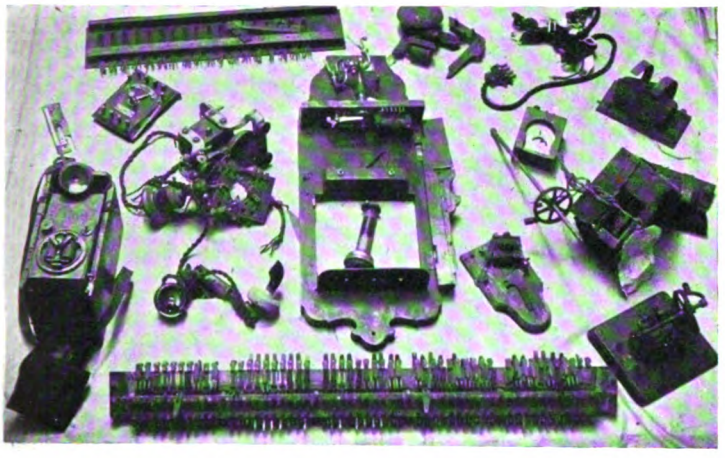

FIG. 1.—SOME "CONDEMNED" INSTRUMENTS.

by the courtesy of Mr. S. J. Goddard we are enabled to publish a brief description of the factory and of the work which is being carried out there. We must also express our indebtedness to Mr. C. E. Fenton, the Factory Manager, for supplying us with all the information contained in this article, and to the Editor of the *National Telephone Journal* for the loan of the blocks used as illustrations, and permission to make extracts from an article by Mr. Fenton in the *Journal*.

Repair work that necessitates the instruments being removed from the subscribers' premises and being overhauled is carried out at the factory, and an average of over 70 tons weight is dealt with every month. Some of those received are in the condition indicated in Fig. 1, and are "condemned," but even these are carefully broken up, and all useful parts are systematically recovered, while the scrap is sorted out so that it may be disposed of to best advantage. The greater part, however, including practically all the instruments of standard type, are renovated in the manner which will be described.

FIG. 2.—A CORNER OF THE POLISHING SHOP.

The instruments after inspection are sorted out into the various patterns, and placed upon racks in warehouses on the ground floor, which occupy a space of about 12,000 sq. ft. They are then taken in hand in large batches as required; a usual number to be dealt with at a time is 100. No attempt is made to examine individual instruments for faults and to repair them in the customary acceptance of the term; the apparatus is taken to pieces absolutely, each part is cleaned and polished, worn out parts are discarded, and the whole instrument is made up afresh. In fact, the instruments which leave the factory are to all intents and purposes new. There is no doubt that this system is the most satisfactory one for dealing with repairs "in bulk." The constituent parts of the instrument are distributed to the various departments, and only come together again in the assembling shop. The backs and other wooden parts of the sets are dealt with in the cabinet department, a considerable portion of which is devoted to French polishing. In another shop, a couple of men will be seen engaged on examining and straightening the cradles of switchhooks. The re-winding of coils occupies another shop, and so on.

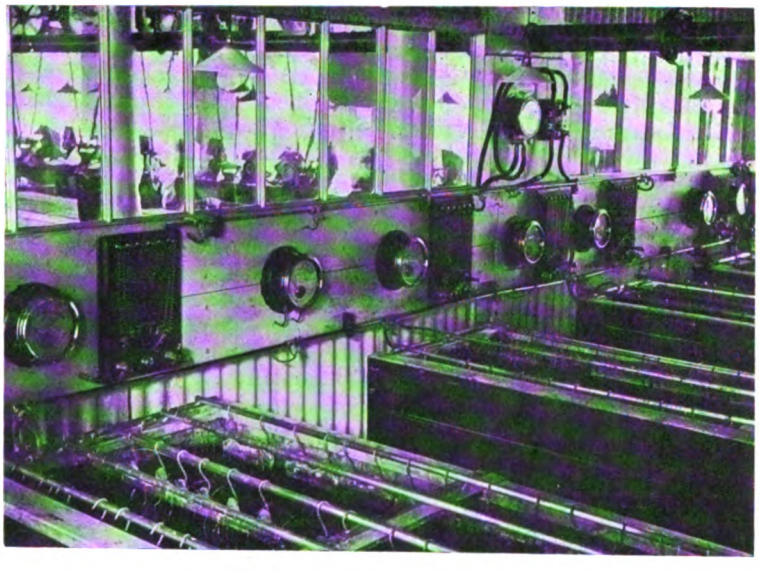

FIG. 3.—NICKELLING VATS.

One of the busiest departments is that devoted to metal polishing. The aluminium parts, such as cases of hand-sets, are scratch-brushed (which produces a matt finish) and afterwards lacquered. The nickel-plated parts have first to be stripped of the old nickel by dipping in *aqua fortis*; they are then polished before nickelling, and again after nickelling (this second polishing is called "colouring off"). It is thus seen that the proportion of polishing work on each instrument is large; some 42,000 parts and 250 gross screws are dealt with each week. Fig. 2 is a view of one corner of the polishing shop. It consists of rows of belt-driven spindles, seventeen double spindles in all, to which mops are attached, and these revolve at a high speed in front of hoods connected by galvanised iron pipes to exhaust fans, which convey the dust to a settling tank outside the building. An interesting feature of this shop is the headgear of the operatives. The cap shown in the illustration fulfils

Digitized by Google

two functions: it keeps the wearer's hair more or less free from dust, but its most important use is to prevent the hair from straggling out, being caught in the air draught, and catching in the revolving brushes. A mixture of beeswax and tallow known as "Tripoli" composition is used on the mops. After the first polishing, the brass parts are wired up and suspended for a few minutes in an electro cleaning bath, which removes the grease. They are then placed in a plating vat until they have received a sufficient deposit of nickel. A view of the four nickelling vats is seen in Fig. 3, and in this shop are also a coppering vat, the cyanide bath, hot potash tanks, hot and cold water tanks, also an electro cleaning bath.

Lacquering is done in a separate shop, together with enamelling. The aluminium cases are coated with a transparent lacquer after they have been matt finished.

The coil-winding department is equipped with 16 winding heads, 13 of which are power driven, and the remaining three, reserved for delicate work, are hand-driven. The activity of this shop is largely dependent on the frequency of thunderstorms.

Switchboards, wall-sets, table-sets, and "sundry" instruments are all repaired and assembled in separate shops, and another large shop (Fig. 4), 110 ft. long, is set aside for the making up of switchboard cable. Separate benches are provided for measuring off, lacing, soldering, and examination. Girls are employed chiefly in this department, but the compression of the cable butts in a machine vice of special construction is done by men.

In dealing with the woodwork, the old polish is completely stripped off, and bruises are taken out by means of sandpaper discs running at a high speed, after which the work is French polished just as new wood would be. Fig. 5 is the shop in which the latter operation is carried out.

Before concluding this article, reference must be made to the bonus system employed at the factory,

FIG. 4.—CABLE SHOP.

which is calculated to increase considerably the industry of each operative. The workers are paid by time, and not by piece work, but for all output beyond a certain fixed minimum a bonus is distributed in proportion to the increased production. This system is found to work excellently in practice, and as the output of every hand has an effect on the bonus that is to be divided, each worker keeps a jealous eye on his or her fellows to see that there is no waste of time.

The whole work and organisation of the factory is of extreme interest, and it well repays a visit, forming as it does an example of a highly specialised factory working under conditions which enable repair work to be treated practically as manufacture.

FIG. 5.—FRENCH POLISHING.

Electric Train Lighting in India.—*The Bombay Gazette* states that the Railway Board has recently addressed a letter to the Secretary of the Indian Railway Conference Association advocating the general adoption of electric lighting in carriages on Indian railways. They call the attention of the railway administrations to the additional injuries and deaths inflicted on the occasion of the late regrettable accidents arising from the gas catching fire and burning the carriages, and they point to the terrible results of fire arising from gas on American railways and occasional similar accidents on English railways. The Board recognise that it is not possible to substitute electric light for gas at once, but consider that steps should be taken in that direction as early as possible. They have therefore been considering what system can best be used on the three State-worked railways—the North-Western, the East Bengal and the Oudh and Rohilkhand—and are favourably disposed towards Stone's system. But this they consider to be a matter for consideration, the essential point being that, whatever system be adopted, it should be used on all lines interchanging stock with each other, so that the staff of each railway can effect the necessary repairs on running trains. The Board, therefore, invite the assistance of the Conference in the solution of the question of the most satisfactory system, and ask that the various Railway administrations may be consulted, and hope that views may be available at the next meeting of the Conference at Simla. This timely notice is given as the Board consider it necessary to issue actual instructions to State-worked railways before the end of the present year, so as to, in future, provide all new carriages with electric light and fit a portion of existing stock with this light.

A Proposed Electrical League.—We are informed that a Provisional Committee has been formed in connection with the proposed formation of an Electrical League to discuss commercial and legislative questions affecting the industry, with a view to finding solutions of the present difficulties. This committee, of which Mr. R. Borlase Matthews is chairman, is composed of the following gentlemen:—Mr. A. K. Baylor, Lieut.-Colonel H. R. Beddoes, Mr. A. N. Connett, Mr. B. M. Drake, Mr. E. Garcke, Mr. H. Hirst, Mr. M. B. Mountain, Mr. S. Rentell, Mr. Mark Robinson, Mr. A. A. C. Swinton, and Mr. A. G Whyte. It is proposed to extend the invitation to join the League to everyone who is in any way interested in electricity, whether shareholder, consulting engineer, town councillor, municipal station engineer, manufacturer, contractor, or trader, whether employer or employee, and every endeavour will be made to work in co-operation with all established electrical societies.

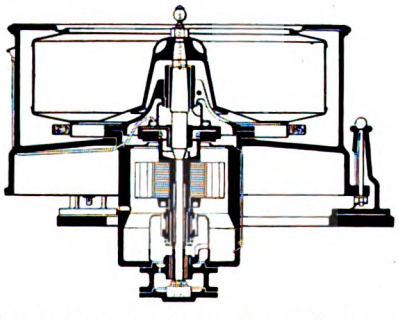
ELECTRICAL ENGINEERING AT THE FRANCO-BRITISH EXHIBITION

IN our previous articles on matters of electrical interest at the Franco-British Exhibition (ELECTRICAL ENGINEERING, May 7th, page 687, Vol. III.; June 18th, page 930, Vol. III.; July 2nd, page 23 and page 143 of our last issue) we outlined the arrangements for the supply of electrical energy to the exhibition, and called attention to some of the principal exhibits of electrical engineering interest, including the collective display organised by the electric supply companies of London; and we propose now to give some further particulars of the power plant working in the exhibition, some examples of the utilisation of electric power, and exhibits of electrical interest to which we have not already referred at any length, including some of the electro-metallurgical exhibits in the French section.

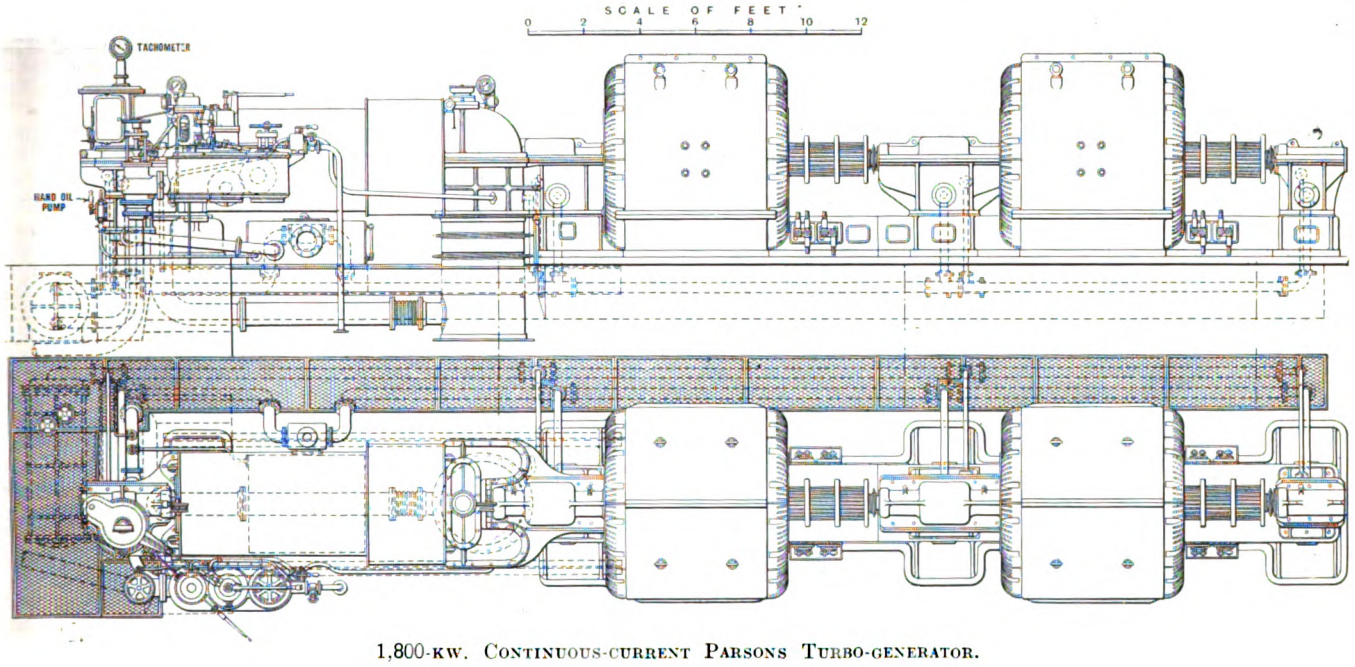
Among the exhibits to which we have only referred briefly on a previous occasion is a hydro-extractor, 48 in. in diameter, of the self-contained electrically driven pattern, on the stand of Messrs. THOMAS BROADBENT & SONS, LTD., of Huddersfield. A section of this machine is given in the accompanying illustration, from which it will be seen that the electric motor is an inherent part of the machine. The armature revolves upon the centre spindle which carries the basket; and the field magnets



48″-ELECTRICALLY-DRIVEN HYDRO-EXTRACTOR.
(MESSRS. THOMAS BROADBENT & SONS.)

are built into the framework of the machine. All the windings of the motor are completely enclosed in an iron casing, so that there is absolutely no possibility of their being damaged by damp or oil. Perhaps the most important feature of this design of electrically-driven hydro-extractor is an ingenious device rendering quite unnecessary any complicated starter and resistance. This arrangement consists in mounting the armature upon a sleeve which is independent of and can revolve round the centre spindle of the machine. To the upper part of this sleeve are attached friction shoes, which are thrown out by centrifugal force when the armature commences to rotate. The weight of these shoes is regulated so that when the motor attains its normal speed the friction developed is equivalent to the power of the motor. The hydro-extractor is then gradually brought up to its proper running speed, although the armature is, of course, running at its full speed the whole of the time. The advantages of this arrangement are that the starting up of the machine is quite automatic; that the attendant cannot damage the motor by switching on the current too suddenly; and that the starting current never exceeds a maximum figure, which can be definitely fixed in designing the machine. The machine shown is driven by a continuous-current motor, but the same system is applied to squirrel-cage induction motors, in which case the method of starting the motor light is even more advantageous.

The power plant in the Machinery Hall actually used for assisting in the supply to the exhibits, as we have already stated, includes a turbo-generator set supplied by Messrs. C. A. PARSONS & Co., of Newcastle, rated at 1,800 kw. at 500 volts continuous current, and capable of 25 per cent. overload for a considerable period. This set, the overall length of which is about 46 ft., consists of a standard Parsons steam turbine running at 1,800 r.p.m., coupled to two generators in tandem. The generators are of Messrs. C. A. Parsons & Co.'s standard pattern, the main features of which distinguishing it from other designs are the retention of the bipolar form for large sizes such as this, and the use of smooth cores, corrugated commutators and metal brushes, and compensation windings without separate commutating poles. The set exhausts into a Körting ejector condenser, and takes steam from the battery of Babcock & Wilcox boilers already described (ELECTRICAL ENGINEERING, Vol. III., page 432). A detailed drawing showing the general arrangement of the set is given in the accompanying figure.



1,800-KW. CONTINUOUS-CURRENT PARSONS TURBO-GENERATOR.

In parallel with this set runs the 500-kw. Westinghouse set, driven by a six-cylinder tandem gas engine of the latest type, to which reference has been made in our previous articles on the Exhibition. The engine is rated at 750 h.p., and is direct connected to a d.c. Westinghouse generator. The cylinders, in pairs, are placed over the three cranks, by which arrangement the makers claim that they can give the most even turning moment of any gas engine on the market. No water-cooling is used for the pistons, valves, or other moving parts, thus avoiding any danger of breakage of pistons, which is sometimes a source of trouble in connection with large horizontal engines. Forced lubrication is used throughout, the oil pumps being in duplicate, and these can be examined and the oil sieves changed whilst

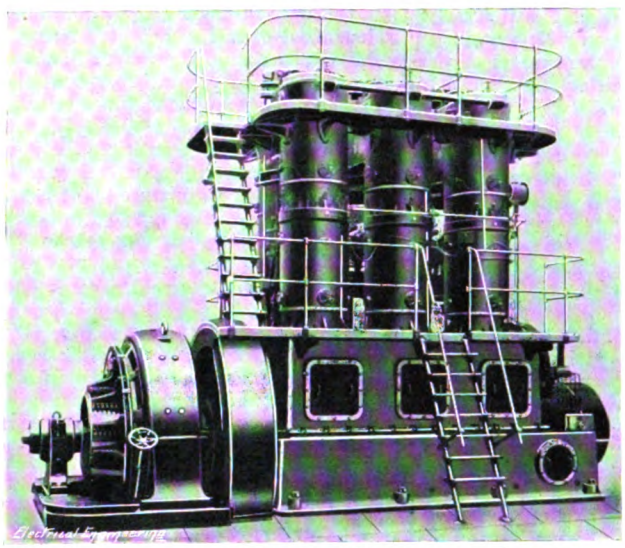
the engine is in operation. All valves are positively operated by means of straight push rods actuated directly from the camshaft. These are also arranged with adjustable screws, so



Generating Set Driven by Six-cylinder Tandem Westinghouse Gas Engine.

that any play or wear can be taken up on these valves whilst the engine is in operation. The set is shown in the accompanying illustration.

The gas-producer, from which the Westinghouse gas engine is supplied, is situated just outside the Machinery Hall, and forms the exhibit of the Power Gas Corporation. It is of a size considerably larger than actually required by this engine, and is really designed for 2,000 B.H.P. The plant consists of two of the well-known Mond Producers, each of seven-foot internal diameter, one patent mechanical washer, one gas cooling-tower, two centrifugal cleaners, two scrubbers, and a governor.

The fuel to be gasified is delivered by means of an elevator into the bunker above each producer, which in turn delivers the fuel into a cast-iron charging hopper at the top of the producer. The fuel, on entering the producer from the charging hopper, goes into a cylindrical bell, which has for its chief object the maintaining of a constant level of fuel. The gas-producer consists of two cylindrical steel shells, one within the other, the inner shell being lined with firebrick, the annular space between them forming an air-jacket in which the air and steam blast is superheated on its way to the space beneath the grate, which consists of specially designed fire-bars set radially in the form of an inverted cone. The producer is of the water-luted type, with lutes all round, and is so constructed that ashes may be removed at all times without interruption of the operation of the producer. In other words, the producer is absolutely continuous in operation. The air-blast is supplied by an electrically-driven Roots blower. The gas leaving the producer passes into a rectangular steel washer, in which it is brought into intimate contact with water sprayed up into the form of rain by quickly-revolving dashers or paddles. By this means the gas is here freed from dust and partially from tar, and is at the same time considerably cooled down. On leaving the washer, the gas enters at the bottom of a gas cooling-tower packed with short earthenware tubes, which effectually distributes over the whole area of the tower the water which is supplied at the top. The gas passes upwards, and on its way comes into intimate contact with the water trickling down. In this tower the gas is much cooled, and a large amount of tar is removed. The gas then passes into a pair of specially designed centrifugal cleaners, into which a small amount of water is introduced. Herein the gas is still further cooled down and freed from tar, and when it leaves this apparatus only contains a small trace of tarry matter, which is removed as the gas passes through the scrubbers, which are rectangular steel boxes fitted with a number of trays, on which are placed simple wood planings or shavings and sawdust. The gas then passes in a thoroughly clean state to the engine. One of the chief points of advantage claimed for this type of plant is that a very cheap fuel can be used, whereas in many other types of plant it is necessary to either use anthracite or a special grade of nut fuel.

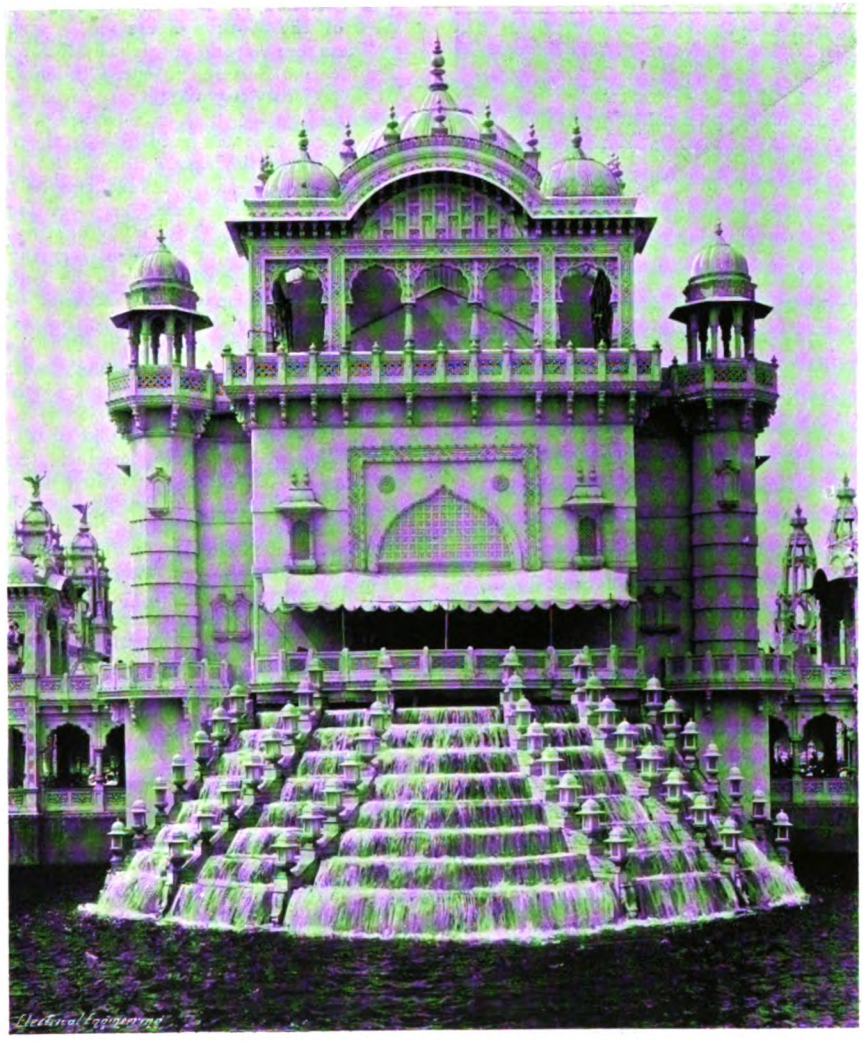
These plants are very simple in operation, and are so designed and constructed that a minimum amount of labour is required for their operation, the production being automatically controlled to give only the amount required by the gas engine even under variable load, thus preventing all waste of gas. The standby losses are extremely small, and, after remaining idle for a fortnight or more, the producer may be brought into proper working condition in about 20 minutes, while after ordinary night stoppages it is only necessary to turn on the blast for about five minutes previous to the gas being actually required at the gas engines.

Mond Gas Plant, exhibited by the Power Gas Corporation.

The circuits from the generating plant described above are taken to two switchboards which have been supplied by Messrs. Crompton & Co., Ltd. Each consists of 2 in. marble panels, with a massive teak framework surrounding each board. These two boards are placed side by side, so that they form practically one complete switchboard. No. 1 board is designed for the control of the Westinghouse shunt-wound generator, and also contains duplicate 500 kw. 500-volt feeder panels. No. 2 board is designed to control the two Parsons compound-wound generators, each 750 kw., 500 volts, and two feeders each for

Digitized by Google

750 kw. The compound windings of these machines have, however, been cut out, and we understand they are now being run as two shunt-wound dynamos. The generator circuits are controlled by two S.P. Crompton circuit-breakers, designed to operate with an overload and reverse current on one pole, and with an overload only on the other pole. The breakers are provided with a magnetic blow-out for final breaking, in addition to the auxiliary carbon brushes and main brushes. The breakers are "fool" proof, inasmuch as the rate of switching on and off is out of the control of the operator. Moving coil amperemeters of Messrs. Crompton's latest pattern are coupled to each dynamo circuit, and the pressure is indicated by three sector type moving coil voltmeters, one fixed at the side, and the others at the top of the switchboards. One of these meters reads the bus-bar pressure, and the others are for reading the voltage of the incoming machines when paralleling. Each circuit is controlled by two overload "C.B.H." pattern circuit breakers of a similar type to those fitted on the generators, excepting that they will only operate with a forward current. An ampere-meter is also coupled in each feeder circuit indicating the feeder current. Equalising switches are fitted on the larger board for coupling to the series windings of the machines, but these are not now in use as the series windings have been cut out for the present. The back part of the board contains the two main bus-bars, the cross section being such that the current density in any part does not exceed 800 amperes per square inch at full load. The main connections are made up of copper bars rigidly bolted to the bus-bars, and the smaller connections to the voltmeters are made by insulated cable. The front of the board is efficiently lighted by means of lamps supported by polished brass brackets fixed to the upper part of the framework. As stated above, these two boards form one complete switchboard, and although it is not done at present it is possible to couple the two bus-bars together by means of links.



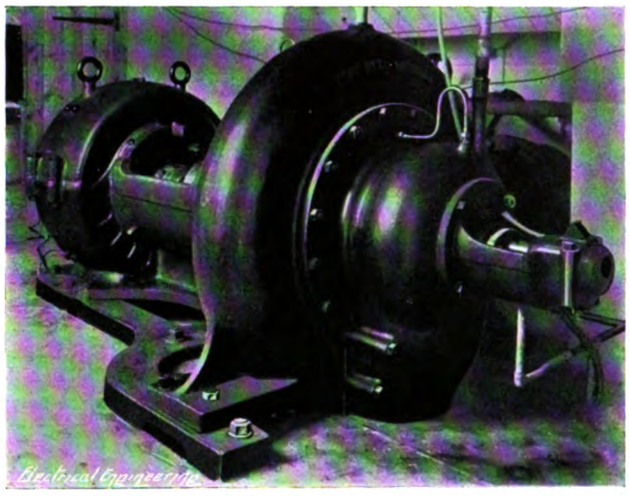
CASCADE IN THE "COURT OF HONOUR."

An interesting example of the application of electric power in the exhibition is the electric driving of the pumping plant for supplying the Cascade in the Court of Honour. The pump-room is situated at the side of the building which contains the Congress Hall, where the annual Congress of the Tramways and Light Railways Association was held. The accompanying photograph shows the Cascade, which is built on to that side of the building which faces the Court of Honour. The work of delivering the water to the head of the cascade is performed by two electrically-driven centrifugal pumps of the "Rees-Roturbo" pattern, supplied by MESSRS. THOMAS PARKER, LTD., of Wolverhampton. One of these pumps is in the pump-room, at the side, where it can be seen through a window, and is illustrated herewith, and the other is situated on a platform under the cascade. Both pumps are direct-coupled to 500-volt continuous-current motors of about 30 B.H.P., and are controlled from a double panel switchboard in the pump-room. Each panel contains an ammeter, voltmeter, double-pole switch, fuses, and an overload circuit-breaker. A starter and a shunt-field regulator for each machine are also provided. The latter enable the speed of the motors, which run at 530 r.p.m., to be increased 30 per cent. if necessary. Each pump normally delivers about 3,000 gallons of water per minute, or 180,000 gallons per hour, against a head of about 25 feet. The total amount of water delivered by the two pumps to the Cascade is some 16,000 tons during a working day of 10 hours. The length of the suction-pipes to the pumps are 14 ft. and 15 ft., and the suction-heads are 7 ft. and 10 ft. respectively. Both suction and delivery pipes have a diameter of 14 in. Each motor was really designed for a capacity of 2,500 gallons per minute against a head of about 45 ft., but the particular characteristic of the "Rees Roturbo" pump is that it will adjust itself to any conditions of working without it being necessary to alter the speed, and without any chance of overloading the motor. Thus these same pumps could have been used for working a fountain with a head of over 70 ft., the volume of water only being automatically reduced in inverse proportion to the head, so as to keep the load on the motor constant. In fact, the construction of this type of pump is such that the power goes down with excessive head, and with a very small head the volume only increases to such an amount that the load remains constant. It was hoped that there would be an opportunity of demonstrating this property of the pump at the exhibition by working fountains with variable heads in the Court of Honour and other Courts, but this was found impracticable, owing to the boat traffic on the lagoons. A point worthy of mention is that in each section and on each step of the Cascade, extra feed-pipes with adjustable valves are placed, so as to give an equally heavy flow of water on the wide lower steps as at the top of the cascade. There are in all 96 such feed-pipes. The delivery pipes from both pumps feed in a common perforated main at the head of the Cascade. In the "Rees Roturbo" pump the water first enters a rotating impeller which is always full of water at a high pressure so long as the pump is working. From the periphery of this impeller, the water escapes tangentially out of "Venturi-shaped" nozzles in a direction opposite to that in which the impeller is rotating. The pressure of the water in the impeller is converted into velocity in the first part of the impeller nozzles, and then leaves the impeller with a velocity about equal and opposite to the impeller velocity. It then enters external fixed expanding channels at a high pressure, but with practically no velocity, having produced a propelling or turbine effect on the impeller due to the reaction of the issuing jets. It is due to this turbine effect that the power absorbed when running at a constant speed remains practically constant for all heads of discharge, and never appreciably exceeds that required for the head for which the pump is designed. The efficiency of this

Digitized by Google

type of pump is very high; one example, designed for an output of 45,000 gallons per hour against a head of 65 ft., had a full load efficiency of 70 per cent.

Another notable example of electric power in the exhibition applied to what may be termed amusement engineering is the driving of the "Flip-flap." The appearance of this remarkable structure, with its two lattice steel counter-weighted arms, each moving through an angle of a little over 180° in opposite directions, and carrying at their extremities cages containing passengers, is too well known to need description, but the method by which these are driven by a single electric motor, and the precautions taken to ensure safety of control, are of some interest. It should be said, first of all, that the main counterweights are equivalent to the arms plus the fully-loaded cars, so that the least power is required when the cars are full, and the tendency in case of accident is rather for the arms to rise than fall. The driving gear for the live arms is connected together by a pair of central bevels driven by the motor, so that



ELECTRICALLY-DRIVEN REES-ROTURBO PUMP SUPPLYING THE CASCADE IN THE COURT OF HONOUR.

the wind pressure is balanced in such a way that the motor only has to overcome the load due to the difference in the wind pressure on the two arms. The motor is rated at 100 b.h.p. at 500 r.p.m.; it is shunt wound, and is supplied by a special 500-volt continuous power feeder from the sub-station adjoining the Machinery Hall. It drives the vertical bevel shaft through worm gear. Each driven shaft carries a pair of sprockets, from which the power is transmitted by chains to the triple reduction spur gearing on each side of each arm, and differential gears are provided to ensure equality of drive on both sides of each arm. There are thus four sets of gearing, all driven by the one motor. Jockeys are fitted by which the slack of the chains can be taken up, as these are rather long. An important feature of the gear is the set of brake drums, 34 in. in diameter and 4½ in. wide, on the first pinion shaft of the spur gear, upon which wooden brake shoes are applied by the four solenoid brakes whenever the current is cut off or fails, after the manner of the usual electric crane brake. These solenoid brakes are fitted with dashpots, so that they can be taken off instantly but only applied gradually. Hydraulic buffers are placed to receive the ends of the arms in case the stopping is not accurate, and a most ingeniously designed locking gear is fitted to lock the arms when passengers are entering or leaving the cages. The locking bolts are connected to contacts which control the circuits of green and red signal lamps in the driver's cabin, and there are also similar signal lamps on the platforms, which operate in the way described below. Further safety devices consist in limit switches preventing the driver overrunning the platforms, and emergency switches on both platforms by which the motor can be stopped and the brakes applied at any time independently of the driver. The apparatus in the driver's cabin comprises, besides the actual drum type controller with its resistances, a solenoid operated main switch, which plays an important part in the system of control. Suppose now the arms are both locked and passengers are going on board, the red signal light circuit is closed at all points. The attendant at one end draws his locking bolt when he is ready; this puts out the red lights and warns the driver, and also closes contacts at that end in the green lamp and solenoid circuits, but these two circuits are not completed until the attendant on the second platform also withdraws his bolt. When this is done the green lamps light up, and the solenoid switch in the main motor circuit is closed ready for the driver to use his controller. He then starts up the motor and runs the trip, being able to stop accurately by a system of sighting arrangements. During the trip the motor can be stopped independently of the driver in the following ways: By a temporary failure of current, by an emergency switch, by an improper closing of one of the locking bolts, or by the working of the limit switches; but it is important to notice that in none of these cases can the machinery be restarted except by bringing the controller back to the zero position and making a fresh start. The way this is ensured is by arranging that the solenoid switch only has its full current through its coil when the controller is in the off position; in all other positions a resistance is in the solenoid circuit, which brings down the current to a value sufficient to hold the armature on but not to pick it up. The main solenoid switch is provided with carbon contacts and magnetic blow out, suitable for 200 amperes at 500 volts. It should be said that the contract for the flip-flap was given to the Cleveland Bridge and Engineering Co., of Darlington, and the electrical and mechanical equipment was designed by Mr. C. W. Hill, under whose direction this part of the work was erected.

There are several electrometallurgical exhibits in the French Engineering Section. Mons. Gin shows a very interesting model of his circulating induction furnace, which is used for the manufacture of high-class steels. By taking off the top of the model one sees readily how the circulating canals operate. The steel in the canals forms the secondary of the furnace, and when sufficiently refined can be tapped out of the furnace by tilting it, there being an electro-motor placed underneath it for this purpose. This style of furnace is installed and used in Krupp's works at Essen in Germany. On the same stand are also shown photographs of the electrode furnace, in which ferro-alloys are made, and samples of ferro-silicon, ferro-tungsten, ferro-molybdenium, ferro-chrome and ferro-vanadium, and manganese silicon are exhibited. One photograph is especially interesting, in which the carbon electrodes are shown after they have been in use, and one can see how they have been eaten away at the one end, that in contact with the molten slag.

The Société d'Electro Chimie of Paris show some magnificent specimens of electrolytic products, such as potassium, sodium and barium chlorates, ammonium perchlorate, a block of metallic calcium and also calcium hydride, besides which they show pure aluminium, chromium, manganese, and ferro-titanium.

The Société Metallurgie Française have an interesting exhibit in which they show a model of the Héroult electrode furnace for the manufacture of special tool steels. A sample of pig iron made in this furnace is also shown, and various pieces of high-speed tool steel. In the same stand there is an exhibit of aluminium in the form of ingots and bars shown by the Ste. Ane. Des Alliages Cothias (Paris).

Near this is the exhibit of the Procédés Company in connection with Mons. Paul Girod, showing ferro-chrome, ferro-tungsten, ferro-molybdenum, ferro-tantalum, and ferro-silicon, all made in Girod's special electric furnace, which, however, they do not exhibit.

Electric Railways in the Alps.—According to the *Elektrotechnischer Anzeiger*, the Bavarian Government proposes to construct a system of narrow-gauge electric railways in the Bavarian alpine district, in order to encourage the tourist traffic. The district would include the fourteen highest peaks of the Bavarian Alps.

Wireless Telegraphy.—A station is now being erected in the grounds of the Vatican at Rome. The transmitting and receiving instruments will have a range of about 350 miles. A large wireless station has also been opened recently at Emden, in East Friesland, Germany, and operators desirous of entering the service on the large ocean liners will be examined there in future.

Speed Indicators on Tramcars.—The Board of Trade is inquiring into a suggestion that speed indicators should be fitted to tramway cars. The Board has asked all tramway and automobile organisations for any information which they may possess regarding the trustworthiness and the cost of any speed indicators now on the market. They add that for the purposes of tramcars it is desirable that the indicator should be reliable for speeds as low as four miles an hour, as well as for maximum speeds.

Liverpool and District Electrical Association.—The following have been elected as President and Council for the ensuing year:—President, Mr. H. E. O'Brien; vice-presidents, Messrs. J. A. Crowther and C. W. Mallins; Members of Council, Messrs. H. W. Brooks, J. Greenhalgh, W. H. Hamilton, R. A. Lambert, C. I. Moore, J. Maxwell, and J. J. Richardson; hon. secretary and treasurer, Mr. S. Frith; assistant hon. secretary and treasurer, Mr. J. T. Stanbury.

THE MARSEILLES ELECTRICAL EXHIBITION

ALTHOUGH officially the Marseilles Electrical Exhibition has been open for more than two months, it is only comparatively recently that the exhibits of electrical interest have been completed, and it was only on June 6th that the main buildings were even opened. By this time, however, the display is more complete, and a few weeks ago members of the French technical Press were invited to view the exhibition, the main features of which were explained by Prof. Fabry, of Marseilles. It is to articles in some of our French technical contemporaries that we are indebted for the information given here.

The site of the exhibition, the Parc du Rond Point du Prado, is nearly two miles from the centre of the town. It was formerly a military parade ground, about 62 acres in extent, but was transformed into a park two years ago, when a Colonial exhibition was held there. The supply of electricity for the purposes of the exhibition, for which some 2,500 kw. is required, is taken entirely from external sources, as it was decided not to erect any steam-driven generating plant within the exhibition. The supply is divided up in the following way.

The Compagnie d'Electricité de Marseille has arranged to supply 1,000 to 1,200 kw. in the form of three-phase current at 5,000 volts and 50 cycles, and a further three-phase supply at 5,500 volts, and the same frequency, amounting to 600 kw., is taken from the system of the Société du Gaz et de l'Electricité de Marseille. The remainder, another 500 or 600 kw., is supplied by the tramway company at 5,500 volts, 25 cycles. Special cables from the feeding points or stations of these undertakings take the high pressure supply to the main distributing switchboard in the exhibition.

The main switchboard, which is placed in the Palais de l'Energie, was constructed by the Société Industrielle des Téléphones. In addition to the incoming and outgoing feeder panels, provision is made for the control of two converting sets, which supply continuous current to a three-wire network with 220 volts between the outers. One of these sets, manufactured by the Société Alsacienne de Constructions Mécaniques, of Belfort, is of 500-kw. capacity, and will eventually be placed in the station of the Compagnie d'Electricité de Marseille, where four sets of similar size are already in operation. The other set, which is for 300 kw., is made by the same firm, and is destined for one of the sub-stations of the Société du Gaz et de l'Electricité. The equipment further comprises a small balancer set consisting of two 50-kw. machines by the Société l'Eclairage Electrique, coupled together. From the main board are taken feeders, through which the distributing network in the exhibition is supplied through sub-stations containing transformers stepping down to 190 and 100 volts, and aggregating about 500 kw. on each of the two sections of the network supplied by the two companies already mentioned. The distribution system for the 5,500-volt, 25-cycle supply is taken to another sub-station. In this has been installed a Thury motor-generator of about 225-kw. capacity, which supplies the 2×110-volt continuous-current networks, with the assistance of a small balancer set of the firm of Fabius Henrion, of Nancy. There are also three 100-kw. transformers, which supply some of the illuminations, and also current to exhibitors, and in the same building is the Rateau-Brown Boveri electrically-driven pump, which absorbs about 600 h.p., and supplies the cascades and fountains. The general lighting of the exhibition is by 450 arc lamps, and the illuminations include more than 40,000 incandescent lamps, requiring about 1,200 kw. An excellent effect is produced by the inclusion of a number of mercury vapour lamps in the scheme of the illuminations.

The exhibits are contained in four palaces, named respectively, Le Palais de l'Energie, Le Grand Palais, Le Palais de la Traction et des Mines, and the Palais de l'Agriculture. The first of these, which comprises on one façade a *château d'eau*, with illuminated cascades and symbolic groups of figures, and is decorated internally with a series of paintings, representing allegorically the progress of electricity, is about 500 ft. long. In it are to be found exhibits relating more particularly to the distribution of electrical power and its applications to military purposes, navigation and the chemical metallurgical and other industries. Here the principal power supply authorities in the south of France and elsewhere have stands where the development of their systems is demonstrated by plans, photographs, &c., and a large relief model illustrates the scheme for the supply of power from the Rhone to Paris, at 120,000 volts, three-phase, proposed by Messrs. Blondel, Harlé, and Mahl. The principal French manufacturers have stands whereon are exhibited dynamo motors, switchgear, and other apparatus; the leading Continental cable-makers are also represented, and cables are shown under test with voltages of 100,000 volts alternating, and 300,000 volts continuous (or, rather, rectified). There is also a good display of line material, insulators, &c., for 50,000 volts, the pressure used in the neighbourhood of Marseilles by the Société l'Energie Electrique du Littoral Méditerranéen for transmission lines up to 62 miles in length. In the electrochemical section are to be found samples of electrolytically-refined copper and the various commercial products of the electric furnace, including aluminium, calcium carbide, and various metals and alloys. There are also models and drawings of various electrometallurgical works and furnaces. The Société de l'Azote has plans and diagrams demonstrating the Birkeland nitrogen furnace, and there are a number of exhibits relating to the uses of electricity in the chemical laboratory. The exhibits relating to the purification of water by ozone, although properly belonging to this section, are contained in the Grand Palais. Several accumulator manufacturers show cells and plates, and a lorry driven by Edison accumulators is shown by the Bergmann firm. A fine model of a lighthouse lamp is exhibited by the Ministry of Public Works.

The Grand Palais is a permanent building about 300×150 ft., which has been erected by the Municipality of Marseilles with a view to future use for exhibition purposes, and is decorated with symbolic sculpture. The electrical exhibits therein relate chiefly to branches of electrical activity which do not involve heavy machinery, including lamps and lighting, telephones, telegraphs, medical apparatus, measuring instruments, and educational appliances. Prominent among the exhibits are samples of various patterns of metal filament lamps, artistic electric light fittings, and a very complete display of meters by well-known Continental firms. The department of posts and telegraphs have a large display of telegraph apparatus. In this building there is also an interesting historical collection comprising, amongst other things, the original ring armature of Paccinotti, rotary field motors made by Ferraris, and one of the alternators of the famous Frankfurt-Lauffen transmission.

The Palais de la Traction et des Mines contains a good deal of electric tramway material, but none of the electric railway exhibits have yet been completed; it is stated, however, that they will include a motor truck for the Chamonix railway, together with a snow plough and apparatus illustrating Messrs. Auvert & Ferrand's single-phase rectifier system, shown by the P.L.M. Railway Co. In the mining section is a mining locomotive of the French Thomson-Houston Co. for a mine near Marseilles, together with electric rock drills and coal cutters There is, however, a certain amount of traction apparatus in the Palais de l'Energie, including a Brown Boveri single-phase commutator motor, and a train-lighting equipment.

In the agricultural section the possibilities of electrical power as applied to agriculture are demonstrated on a model farm by the Société le Sud Electrique, and in this section are shown cooking appliances, pumps, ozone water purification apparatus, sewing machines, electric flat irons, kneading machines, lixiviation apparatus, crushers, churns, cream separators, ice-making machinery, sheep-shearing machines, chaff-cutters, oil-presses, &c.

A wireless telegraph installation has been established by the Société C.G.R., which is provided with a fan-shaped aërial supported by two masts each about 100 ft. high. Communication is maintained with the Eiffel Tower, and experiments have been made with wireless telephony on the de Forest system. Another feature of the exhibition is a complete furnished villa in the grounds, equipped by the Société du Gas et Electricité de Marseille, to demonstrate the various applications of electricity to domestic purposes, in a similar manner to the flat in the collective electrical exhibit at the Franco-British Exhibition. The equipment comprises lighting and power applications, electric lifts, vacuum cleaners, and heating and cooking apparatus of every kind, including even electrically-heated rugs and eiderdowns.

Electricity from Peat in Germany.—On page 139 of last week's issue we gave some particulars of a scheme for erecting a power station in the East Friesland peat district. Preparations are now being made for the building of another large power station in Holstein. The work has been undertaken by the firm of Gebr. Körting Akt. Ges. The large gas engines will be supplied from gas producers generating the gas from air-dried peat. The generating costs are estimated at 0·1d. per horsepower-hour. Electrical energy for light and power will be distributed to various local authorities and manufacturing concerns within the district.

THE MANUFACTURE OF METAL FILAMENT LAMPS

AN article by H. Remané, of the Deutschen Gasglühlicht A.-G. (Auer-Gesellschaft), in a recent issue of the *Elektrotechnische Zeitschrift*, deals with the possible future development of the metal filament lamp from the point of view of the lamp manufacturer. The Auer-Gesellschaft are the manufacturers of the Osram lamp, and some interesting information, relating to the difficulties encountered in the manufacture of high-voltage, low-candle-power Osram lamps, is given in the article. One of the first questions to be considered, writes Mr. Remané, is, what will be the candle-power of the normal metal filament lamp, corresponding to the present 16 c.p. carbon filament lamp? The latter has become the standard, not on account of its convenient intensity as an illuminant, but because the cost of the energy consumed by such a lamp was already high enough, and a larger unit would consume more. The normal incandescent gas unit is nominally 60 c.p., and now that the working costs for electric incandescent lighting have been so much reduced, there is every reason to expect that the normal lamp of the future will be at least a 32-c.p. lamp. In places where the cost of energy is high, as, for example, in Paris, 25-c.p. lamps are at present preferred, while in Berlin, Leipzig, and other cities where energy is comparatively cheap, 50-c.p. lamps are more generally employed.

With regard to the best pressure for lighting circuits, the higher voltages will always be unfavourable to the metal filament lamp, as has been the case with the carbon filament lamp. Taking the consumption of a 110-volt lamp at 1 watt per hefner candle, experience has shown that the consumption of 220-volt lamps of from 40 to 100 candle-power, with the same light constants and the same life, will be 1·25 watts per hefner candle. It is quite possible that this figure will be reduced a few per cent. in the future, but the low-voltage lamp will always have the advantage. There is at present little prospect of a 32-c.p. 220-volt lamp consuming less than 1·4 watts per hefner candle appearing on the market, and still less prospect of a 25-c.p. 220-volt. for less than 1·6 watts per candle appearing. Under such conditions, in order that a consumer on a 220-volt circuit may obtain his light at the same cost as another on a 110-volt circuit, both using 32-c.p. metal filament lamps, the price of energy per kilowatt-hour would have to be 30 per cent. cheaper in the former case. The saving in generation and distribution obtained by the adoption of the higher pressure would not, in most cases, amount to as much as 30 per cent., and, consequently, the author concludes, it will be more to the advantage of the consumers if distribution is effected at 110 volts.

The chief difficulty encountered in the manufacture of the high-voltage lamp is the extreme fineness and excessive length of the filament. A comparison between the diameters and lengths of carbon and Osram (tungsten) filaments for equal pressures and candle-powers is shown in the table below. The consumption in watts per hefner candle is also given in each case. These figures for consumption, with the exception of that for the 16-c.p. 220-volt lamp, were experimentally obtained.

Diameters and Lengths of Carbon and Tungsten Filaments for Various Voltages and Candle-powers.

	Candle-power and voltage.	Average diameter in mm.	Average length in mm.	Watts per hefner candle.
Carbon filament...	50/220	0·13	400	3·0
	32/220	0·12	380	3·5
	25/220	0·085	350	3·5
	16/220	0·07	275	3·5
	10/220	0·06	265	4·0
	50/110	0·23	240	3·0
	32/110	0·18	230	3·1
	25/110	0·16	220	3·1
	16/110	0·12	200	3·1
	10/110	0·075	175	3·5
Osram filament ...	50/220	0·0342	1040	1·25
	40/220	—	—	1·25
	32/220	0·0254	910	1·25
	25/220	0·0216	826	1·25
	16/220	0·0154	723	1·10*
	50/110	0·0530	605	1·10
	32/110	0·0395	524	1·10
	25/110	0·0328	490	1·10
	16/110	0·0244	410	1·10

* These figures are calculated, as this type of lamp has not even been constructed on an experimental scale.

The Auer-Gesellschaft manufactures short lengths of tungsten filament with a diameter of 0·020 mm. for low-voltage lamps with a consumption of 1·0 watt per candle, but the difficulties in the way of producing in large quantities long homogeneous threads of that diameter seem insurmountable. High-voltage lamps of this type are also very fragile, and have short lives.

ELECTRIC LIGHTING ORDERS, 1907

THE annual report respecting application to, and proceedings of, the Board of Trade under the Electric Lighting Acts, 1882 to 1902, during 1907 shows that of the 27 applications, 17 were by local authorities, and ten by companies or persons. The Orders granted have been submitted to Parliament as follows:—

Electric Lighting Provisional Order Confirmation Bill, Nos. 1 and 2.—Bispham-with-Norbreck, Caldy Manor, Carmarthen, Fleetwood, Halesowen, Heswall, Lowestoft (Amendment), and Woking (Extension); Barrhead, Clydebank (Amendment), Dundee (Extension), and Rutherglen (Amendment).

Electrical Lighting Provisional Order Confirmation Bill, No. 3.—Bridgend (Extension), Hendon (Amendment), Llandaff and Dinas Powis (Amendment), Llansamlet, Oulton Broad, Sowerby Bridge (Amendment), and Tewkesbury.

The application for the Smethwick Electric Lighting Order, which at the date of the last report was still under the consideration of the Board of Trade, was subsequently withdrawn by the promoters.

The Rural District Council of Barton-upon-Irwell applied for an Order to enable them to transfer their powers obtained in 1906. The Board of Trade were not satisfied as to the financial position of the company, who were proposed as transferees, or that the company wished to take a transfer, and the Order was refused. The Rural District Council of Bath promoted an Order but did not proceed with the application. Broadstone, Ltd., applied for an order for the Fleetwood district, but did not proceed with the application. In the case of the Johnstone (N.B.) Electric Lighting Order promoted by the Strathclyde Electricity Supply Company, the promoters failed to produce the consent of the Local Authority or to satisfy the Board of Trade that the consent should be dispensed with, and the Board refused to grant the Order. In the case of the Lowestoft (Extension) Order, this confers further powers upon the Corporation in respect of their existing undertaking in Lowestoft, but the application included in it, for the Urban District of Oulton Broad, was refused, a separate Order being granted to that Urban District Council. In the case of the Macclesfield Electric Lighting (Amendment) Order, this was promoted by the Corporation to transfer their powers under an Order obtained in 1901 to a company. The Board of Trade, however, was not satisfied as to the financial position of the company who were proposed as transferees, and the Order was not granted. In the case of the Woking Electric Supply (Extension) Order the promoters, the Woking Electric Supply Co., Ltd., withdrew the application in so far as it related to the Urban District of Staines and Egham, and the Order was granted in respect of the remainder of the area included in the application.

Since the date of the last report the under-mentioned Orders have been transferred:—Annfield Plain, 1901 (Cleveland & Durham County Electric Co.); Arbroath, 1907 (Arbroath Electric Light & Power Co.); Benfieldside, 1901 (Cleveland Durham County Electric Power Co.); Bude, 1906 (Bude Electric Supply Co.); Calverley, 1903 (Electrical Distribution of Yorkshire, Ltd.); Chesham, 1901 (Chesham Electric Light & Power Co.); Chichester, 1898 (Chichester Electric Light & Power Co.); Consett, 1901 (Cleveland & Durham County Electric Power Co.); Farsley, 1906 (Electrical Distribution of Yorkshire, Ltd.); Hartlepool, 1899 (Cleveland & Durham County Electric Power Co.); Hoddeston, 1901 (North Metropolitan Electric Power Supply Co.); Leadgate, 1902 (Cleveland & Durham County Electric Power Co.); Ossett, 1898 (Electrical Distribution of Yorkshire, Ltd.); St. Albans, 1898 (North Metropolitan Electric Power Distribution Co.); Smethwick, 1898 (Birmingham & Midland Tramways, Ltd.); South Bank-in-Normandy, 1902 (Cleveland & Durham County Electric Power Co.); Stanley, 1902 (Durham) (Cleveland & Durham County Electric Power Co.); Uxbridge and District, 1903 (Metropolitan Electric Supply Co.); Wisbech, 1901 (Wisbech Electric Light & Power Co.).

The Fire on the City and South London Railway.—Colonel Yorke and Mr. A. P. Trotter resumed their inquiry on Saturday last into the fire which occurred on the City and South London Railway on the 16th inst. No further evidence was called, however, the Board of Trade officer spending a considerable time in the tunnels where the fire took place, and further questioning the witnesses who gave evidence on the 20th inst., reported in our last issue.

The Fire Brigade Committee of the London County Council have considered a report of the Chief Officer of the Fire Brigade on this fire, and state that this raises several questions of importance in connection with tube railways generally, and the City & South London Railway in particular, upon which they think it will be advisable for the Council to make representations to the Board of Trade. They state that they have called for further reports on the subject, and in view of the approaching recess they ask to be authorised to make any representations to the Board of Trade as soon as these reports shall have been considered.

THE TANTALUM WAVE-DETECTOR

A PAPER was read by Mr. L. H. Walter before the Royal Society on May 7th last, in which the author's Tantalum Wave-Detector and its Application in Wireless Telegraphy and Telephony was described. It has been known for some years that the metal mercury lends itself well to the purpose of constructing a detector of electric oscillations which is capable of spontaneously returning to its initial or sensitive condition, or, in other words, is spontaneously decohering. Iron, carbon, and platinum have all been tried for this purpose in conjunction with mercury, but possess several disadvantages.

The advent of the tantalum lamp, which appeared to promise that this hitherto unobtainable metal would soon be commercially available, seemed to hold out some possibility of successfully overcoming the previous difficulties in the way of finding a suitable noble metal. For the fact that tantalum is a noble metal in so far as its chemical behaviour is concerned, that it is indifferent to atmospheric influences, that it has great strength and ductility, and, finally, that it is absolutely indifferent to mercury, seemed to bear out the above view.

A first experimental detector was made by passing two tantalum wires, taken from an ordinary tantalum lamp, down two fine glass capillary tubes, and allowing the wires to project about 1/20 inch, and their points to just touch the surface of a small pool of mercury. Trials of this detector gave good results, and it was found that both the liquid dielectric and the insulating sheathing could be dispensed with. The general construction and actual size of the detector as now used is shown in section in Fig. 1, the whole arrangement being hermetically sealed in a glass bulb.

Here P is a sealed-in platinum wire, forming one terminal, dipping into a small pool of mercury M, in the glass vessel G; the other terminal is also a platinum wire P_1, having a clip at its end, holding a short length (3/16 inch about) of tantalum wire T of 0·05 mm. diameter. The sealed-in platinum loops form a handy means of connecting up, with the aid of a lamp-holder of the Swan type. Before sealing up, mercury is poured into the bulb, through a small side neck N, to such a level that the tantalum point is just immersed, which is best ascertained experimentally by the sound in the telephone receiver. The bulb can then be sealed, having previously been exhausted, if so desired. When properly constructed, such detectors appear to be permanent, and not to deteriorate, nor have they been found fragile in transport.

Detectors of this form have been tested at actual wireless telegraph stations, and it has been found that, while possibly not so sensitive for very weak oscillations (signals) as the electrolytic or magnetic detector, for slightly stronger oscillations the sound is several times louder than that obtained with the elecrolytic, which is itself much more sensitive than the magnetic detector. With the second detector made, very loud signals were obtained at a distance of 70 miles over sea, without any attempt at tuning, louder than those obtained with the electrolytic detector with the aid of a step-up oscillation transformer and careful tuning. Using one of the less satisfactory of the later models of the tantalum detector, loud commercial signals have also been obtained at a distance of 450 miles from an ordinary 2-kilowatt ship installation.

An examination of the tantalum detector by the resistance substitution method shows that in the receptive condition these have a fairly low resistance, 1,200 to 1,800 ohms (as compared with the filings coherer, 100,000 ohms or so, and the electrolytic detector, 30,000 to 50,000 ohms). This low resistance should prove beneficial to the tuning in certain cases. When oscillations are acting, the resistance drops to anything from 250 ohms for strong, to 70 ohms, say, for very strong signals. The great loudness of the signals obtainable with the tantalum detector is due to the large change in the current through the telephones. For this detector the ratio of the current when oscillations are acting to that in the normal condition ranges from 3 : 1 to 8 : 1, and can amount to 30 : 1 without reaching the maximum sound obtainable; the normal current, using 580-ohm telephones, is about 1/20 to 1/10 milliampere.

The tantalum detector is, in the author's opinion, specially suited for wireless telephony. For this application of electric wave propagation the use of microscopically weak signals is out of the question, and here it is that the superiority in loudness of the tantalum detector for moderately strong oscillations comes in.

The form of detector just described, while serving very well for use in fixed stations where a firm support can be obtained, is not so satisfactory when the detector is liable to be subjected to shaking or mechanical shocks during the reception of messages. It was, therefore, thought desirable to find some method of immobilising the mercury, and a satisfactory arrangement was arrived at by constructing the detector in the following manner: The tantalum wire is fastened in a platinum clip, and at the end of the tantalum encased in glass by a special method, necessitated by the impossibility of sealing-in tantalum in the ordinary way as is done with platinum. The platinum wire is sealed into a minute glass bulb B (see Fig. 2) blown on one end of a glass tube; the other end of the tube is connected to an air pump and the interior exhausted. The glass tube is next heated, when the vacuum causes it to collapse on to the tantalum wire. The end of the glass-sheathed wire can then be ground down so that the tantalum surface is just flush with the glass (simply breaking off the glass end usually suffices). The mercury is contained in a glass tube G, having a bore of 5/32 in. A larger tube would be better, but the sensitiveness to shaking then reappears; a smaller tube gives a less sensitive and more variable detector. An ivory plug, *I*, through which a platinum or nickel wire passes and projects, is placed at one end of a length of a few inches of such glass tube with thick walls. A few drops of mercury—enough to form a pellet (*M*) about 5/16 in. long—are then put in, and a second ivory plug, I_1, this one with the sheathed

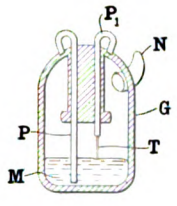

FIG. 1.

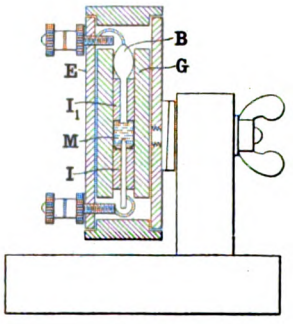

FIG. 2.

tantalum wire passing through it and projecting about 1/20 in., inserted so that the tantalum glass surface just dips into or under the mercury surface. The best (most sensitive) position is that shown in Fig. 2, with the glass tube vertical, and the tantalum electrode at the top, and this gives a detector which may be roughly shaken or tapped during the reception of signals, without affecting their sound in any way. For sealing up, the whole arrangement is encased in an ebonite tube, *E*, and the ends filled in with insulating compound.

As it seemed somewhat remarkable that such exceedingly good results should be obtainable with tantalum, the first metal tried, a series of experiments was carried out, using mercury in conjunction with other metals hitherto untried by the author, especially those which are most resistant to the action of mercury.

In the case of the metals, iron, steel, nickel, and tungsten, and "Eureka" resistance alloy, it was found quite impossible to obtain anything but a "perfect" contact, and no effect at all was obtained with vanadium, molybdenum, cobalt, manganese, tellurium, zirconium, ferro-silicon, ferro-manganese, ferro-nickel, nor with antimony or bismuth. Trying pure tantalum with different solid metals, it was found that a sensitive and moderately loud spontaneously restoring detector can be made by placing a tantalum point so that it bears on an iron surface (best oxidised). An equally sensitive but not quite so loud detector is obtained with a similar arrangement, but using tantalum and tellurium. A very weak effect was observed with cobalt, antimony, manganese, and bismuth in this order of decreasing loudness, while with molybdenum and vanadium there was no effect whatever. But with all these coherers one has only to compare them with the tantalum point dipping into mercury to realise that they are hopeless as practical competitors.

ELECTRIC TROLLEY OMNIBUSES

THE following is an abstract of the report of a sub-committee appointed by the Tramways Committee of the Dundee Town Council to investigate the practicability of a system of railless electric trolley omnibuses for public service in the outlying parts of Dundee.

For some years there has been a strong local demand for some form of vehicular transit in the Clepington Road. Various reports have been prepared, all going to show that, from a financial standpoint, it was impossible to lay down an ordinary tramway in this district. In the 1907 Provisional Order, powers were taken to run motor omnibuses within the city. At a meeting of the committee on March 9th last, it was resolved to instruct the manager to report as to the propriety of running motor omnibuses between Maryfield and Fairmuir via Clepington Road, and to ascertain whether the Board of Trade would permit overhead wires in connection with the installation of the trackless car system. Subsequently the manager submitted his report, which went to show that the trackless trolley system was the most practical and cheapest form of locomotion for a district where the traffic would not warrant the laying of rails, and a sub-committee, consisting of Convener A. Speed, Councillor G. A. Johnstone, Mr. P. Fisher (Tramways Manager), and Mr. H. Richardson (Electrical Engineer), was appointed to visit places on the Continent where such a system was in operation, as no town in Britain had yet adopted it. The deputation left Dundee on June 12th, and proceeded in the direction of Düsseldorf to a town named Monheim, where a trackless system for passengers and goods was owned and worked by the community of Monheim. This system has been in operation here for a number of years, and a traffic has been developed between the railway station of Langenfeld and the town of Monheim, a distance of about two and a half miles, sufficient to warrant the laying of rails. This is an illustration of the value of the railless system in testing and developing a district before the enormous expense of laying an ordinary tramway is undertaken. The overhead poles, wires, &c., for this new system are available when an ordinary tramway is constructed along the same route on which the railless system has been operating. The system might be described as a motor-car or motor-bus obtaining its energy from an overhead wire instead of carrying a prime mover on each individual vehicle. The power is obtained from overhead wires just as is the case on an ordinary electric tramway, with this difference, that two wires are required overhead instead of one, as no earth return is available. On some systems two separate trolley poles are used, but on the more up-to-date systems only one trolley pole is required; this pole is forked near the top with a spread sufficient to allow of the two trolley heads fitting exactly on the two wires. When the deputation visited Monheim they had an illustration of what was possible in the way of distributing produce where small towns were linked up by a system such as they were inspecting. The overhead wires were carried into the goods depôt at the railway station of Langenfeld, the passenger car had a trailer waggon for goods and parcels, the parcels were transferred to the latter and the passengers taken on board the car. The run to Monheim was smartly made, the parcels were transferred to a hand cart, and the deputationists saw several large parcels delivered to different houses in the town one hour and five minutes after the train on which the parcels were brought to Langenfeld left Cologne, altogether a railway journey of something like 20 miles, 2½ miles on the trolley car, and, lastly, the transference to and delivery from the hand cart. The installation at Monheim is one of the oldest of this system, the carriages are very clumsy, with rubber tyres on only the front wheels, the rear wheels having steel tyres.

The next system to be inspected was that connecting the towns of Ahrweiler, Neuenahr, and Walporzheim. For dealing with traffic in this district many schemes have been considered. An ordinary tramway could not be laid down on account of the initial cost. Motor-buses were considered and rejected on account of the cost of working and maintenance. In 1905 it was decided to adopt the trackless trolley system, and a limited company was formed to carry out the scheme. The capital is £7,000, of which the greater portion was subscribed by the town of Ahrweiler and the rest by private persons. The line was opened in May, 1906, for both passengers and goods. In the town of Ahrweiler the streets are very narrow; the paving of the streets is of a sort of rubble, and not so smooth as most of the streets in Dundee. Between the towns the roads are macadamised and have a surface somewhat similar, certainly no better than we are accustomed to. The macadamised roads are about 23 ft. wide. Trailer cars are also used on this system for passengers. Rubber tyres are fitted to all four wheels of the trailers and the riding is comparatively smooth and comfortable. The cars are seated for 20 passengers, and are well and comfortably finished inside. The public authorities sanction a speed of 14 miles per hour on this system along the open roads. From actual figures the amount of electric energy is 0·67 of a unit per mile run, which at the price charged for current in Dundee would amount to about ¾d. per mile. The other items of expenditure are all correspondingly low. The deputationists were very favourably impressed with the serviceable character of this installation, and were thoroughly satisfied that it could be adapted for the requirements of Clepington Road and such districts.

The sub-committee next visited Mulhausen, where the very latest example of this system of traction can be seen. This town has an ordinary tramway system which was constructed and is worked by a company holding a concession for a number of years. The Zoological Gardens of the town lie at the top of a hill, access to which is obtained by a good road with steep gradients for the greater part of the distance. Large crowds of people are attracted to the Gardens, and the want of travelling facilities was very much felt by the inhabitants. The tramway company was approached with a view of getting them to lay a tramway to the Gardens. The company agreed that, as the gradients were too steep for safe working, and that the traffic would only be intermittent, they did not feel justified in constructing a line to this district. Other means were considered, and a deputation of the Council were sent to the valley of the Ahr to study the trackless trolley system in operation there. The deputation returned with a favourable account of the working of this system, and recommended that the authorities themselves erect overhead work, reconstruct some of the streets, and procure vehicles to give a service between the centre of the town of Mulhausen and the Zoological Gardens. The work was carried out on the Max Schieman system with the latest improvements. The work was completed and experimental running was carried on between May 4th and 17th of this year with satisfactory results. After this period of trial the State officials from Strassburg came to inspect the line and carriages with their equipments. During this inspection the car got beyond control of the driver on the steep hill, and but for the excellent steering arrangements on the car, and the coolness of the driver, serious consequences must have resulted. Carriages and other obstructions were on the street, a dangerous curve with a bridge was at the bottom of the hill, and while the driver was unable to retard the progress of the car he was able to steer it clear of all danger. After this experience the State authorities demanded that the vehicles be fitted with more powerful and effective brakes; this has now been done, but another difficulty has arisen between the State authorities and the municipality. The State authorities claim that the system is a railway, and liable to all statutory obligations as such. The local authorities argue that it is only an ordinary road vehicle, deriving its power from an electric circuit instead of being drawn by a horse. Till this question is settled the cars will not be allowed to run. The sub-committee went over the route and found that the gradients were steeper than the steepest part of Albert Street, Dundee, and certainly should not be operated on without very efficient safety appliances.

While the cars here are lighter and more up-to-date than any that had previously been seen, still there are features in them which would unsuit them for British requirements.

The report continues:—During our visit of inspection we corresponded with the manufacturers of the chassis and equipments for this form of traction. They informed us that it was their desire to do business with us through a syndicate in London which had been formed to push this system in Great Britain, we also communicated with the London people from various places on the Continent, and we arranged that one of our number should have an interview with them on our return to London. The results are that draft specifications and approximate estimates of cars have been submitted to us, and we are now in a position to give the committee some idea what it would cost to install such a system on the Clepington Road and provide three cars for the purpose of giving a service thereon if the committee resolve on such a course.

The following are the conclusions appended to the report:—

(*a*) The trackless trolley system of traction is undoubtedly practicable and well suited for routes where the traffic would not warrant the construction of an ordinary tramway, and the sub-committee are satisfied that there is more likelihood of success with this system than any other. (*b*) That the Clepington Road (from Forfar Road to Strathmartine Road) should without delay be equipped with this form of traction. And, further, if the Town Council adopt this recommendation for the limited area already mentioned, the councillor members of the sub-committee are of opinion that the railless system should, as early as possible, be extended from Strathmartine Road via Loons Road to Lochee, thus forming a splendid circular tour by car via Maryfield, Clepington Road, and Lochee, or *vice versa*, and at the same time providing a much-needed connection between Lochee and the north end of the city. (*c*) In the event of the committee and the Council resolving to install the railless system on any route, instructions should be given for submitting all details of the proposals to the Board of Trade.

LONDON COUNTY COUNCIL TRAMWAYS

Accounts for year ended March 31st, 1908

THE accounts for the year ended March 31st, 1908, in connection with the London County Council's tramway undertaking have now been made up, and are reported upon by the Highways Committee. The tramways system on March 31st, 1908, extended over a total length of 119¾ street miles, being 68⅜ miles of electric lines and 51⅜ miles of horse lines, the whole of which is worked by the Council with the exception of a short length of ⅜ mile (double line) in Archway Road, Highgate, which is worked by the Metropolitan Electric Tramways, Ltd. The capital expenditure on the undertaking up to March 31st, 1908, amounted to £8,414,590 15s. 11d., of which £1,468,280 4s. 11d. represents expenditure during the year 1907-8. The total debt repaid up to the same date amounted to £819,376 18s. 11d. out of revenue, and £264,515 18s. 2d. from the proceeds of sales of horses and old materials, &c. The debt outstanding on March 31st, 1908, was £7,330,697 18s. 10d., or, dededucting £68,558 for the value of surplus land, £7,262,139 10s. 10d.. The Council decided on June 23rd, 1908, subject to the approval of his Majesty's Treasury, to repay the debt (estimated at £961,954) on the capital which will have become obsolete at March 31st, 1914, owing to the electrification of horse-tramways, within fifteen years from that date. The present position with regard to this obsolete capital expenditure has accordingly been shown in the accounts for 1907-8. The amount of obsolete capital on March 31st, 1908, was £978,843 14s. 11d. Deducting the debt in respect of such capital repaid out of revenue, viz., £203,243 3s. 4d., the outstanding debt is £775,600 12s. 7d.

The total receipts from the undertaking during the year were £1,663,031 16s. 3d., and the working expenses £1,170,115 12s. 2d., leaving a surplus on working of £492,916 4s. 1d. There was a deficit on the horse tramways of £57,362. After deducting debt charges, &c., there remains a net balance of £45,406 3s. 8d., the whole of which, together with the balance brought forward from the year 1906-7 of £5,923 1s. 11d., a total of £51,329 5s. 7d., has been carried to the renewals fund as on March 31st, 1908.

The Council decided on June 23rd, 1908, that provision should be made for renewals at the rate of two-thirds of a penny for each car-mile on the total car-mileage run on the electric tramways each year; and that the question of the adequacy or otherwise of this provision should be again considered at the expiration of five years. Provision for the year 1907-8 on this basis would necessitate the setting aside of £71,086, and similar provision in each year of electrical working would, with accumulations, have amounted at March 31st, 1908, to £196,741 (£200,733, less expenditure £3,992).

The Council also decided, on June 23rd, 1908, on the recommendation of the Finance Committee, that a "General Reserve Fund" to provide for general contingencies, should be established, and that to form the nucleus of this fund, the sum of £34,634, being the amount of £30,772, the total of the renewals reserve fund on April 1st, 1904, in respect of the horse system, together with interest accumulated to March 31st, 1908, should be transferred to the fund. The accounts give effect to these decisions of the Council.

The total standing to the credit of the renewals reserve fund at March 31st, 1908, was £193,256. Deducting the amount now transferred to general reserve, £34,634, the balance of the renewals fund, as now constituted, is £158,622.

The total operating expenses for electric traction were £724,381 10s., including £6,736 6s. for special charges, or 6·79d. a car-mile run, as compared with 7·06d. a car-mile in 1906-7. The toal working expenses in connection with horse traction amounted to £445,734 2s. 2d., or 10·73d. a car-mile run. Considerable loss was sustained during the reconstruction of horse lines for electric traction, as not only were some of the routes entirely closed, but sections of other routes had to be closed, and this disorganised the whole traffic on important through routes.

The following further facts may be of interest to the Council. The system on April 1st, 1907, included about 58 miles of electric tramways, and during the year a further length of about 10 miles was opened, making a total of about 68 miles. The lines opened during the year are the new tramways from the Obelisk, Lewisham to Lee, from Defoe Road, Tooting, to Tooting Junction and to Merton, and from Goose Green to Peckham Rye, and the reconstructed tramway routes from Great Eastern Street to Norton Folgate, along Hackney Road, along City Road (from Old Street) and Pentonville Road, along Goswell Road, along Gray's Inn Road, and from Highgate to Highbury. The average fare per passenger was 1·05d., the same as in 1906-7.

The total number of units generated during the year at the Greenwich generating station was 51,805,633, and the cost amounted to 0·570d. a unit, including interest and sinking fund charges, as compared with a cost during 1906-7 of 0·676d. per unit. These figures relate to generation only.

The toal number of passengers carried during the year was 372,515,754, of which 279,166,461 were carried on the electric cars. The total number of car-miles run was 35,561,189, electric traction being represented by 25,591,028.

The Finance Committee, in reporting upon the accounts, states that there are certain features to which they think it desirable to direct the attention of the Council. The accounts follow the same general lines as adopted last year, but as the result of the recent decisions of the Council on Messrs. Peat and Pixley's report, the balance sheet shows separately the proportion of the capital expenditure on horse traction which had been rendered obsolete up to March 31st, 1908, by the conversion of the lines to electric traction, and *per contra* the amount of debt thereon repaid out of revenue. This shows that the outstanding debt in respect of obsolete capital up to March 31st, 1908, was £775,601. Moreover, the details of expenditure have been relegated to the supplemental statements; the "renewals reserve fund" has been altered to "renewals fund"; and a "general reserve fund" has been formed.

The surplus for the year is £14,529 less than the original estimate, and £25,174 less than the revised estimate of the year based on nine months' working prepared in connection with the estimates for the current financial year. The interest and sinking fund charges met out of the surplus of £492,916 amounted to £450,024 (£17,604 less than the original estimate, which made too large a provision for charges on estimated further expenditure), and other charges against the surplus reduce the balance for the year to £45,406. This shows a slight improvement over the original estimated surplus balance for the year (£41,788), but is £21,141 less than the revised estimate.

The renewals fund has been increased by the net surplus of £45,406 and by the balance on the appropriation account on April 1st, 1907, of £5,923 and dividends on stock and interest on the cash balance during the year. Expenditure on renewal of special work amounting to £3,993 and expenses of investment £192 were defrayed out of the fund.

In accordance with the resolution of June 23rd, 1908, a sum of £34,634 in respect of the balance on March 31st, 1904, of the renewals reserve fund of the horse system (£30,772), together with accumulations to March 31st, 1908, at 3 per cent., was transferred to a special fund to be called the "general reserve fund," leaving the balance on the renewals reserve fund on March 31st, 1908, of £158,622. Provision for renewals at two-thirds of a penny per car-mile, the basis recently adopted by the Council, would require £71,086 in 1907-8, as compared with £45,406, the actual surplus of the year, but the results of the year were adversely affected by the reconstruction works which were in progress. If provision for renewals at two-thirds of a penny per car-mile had been made from the beginning of the working of the electric lines, the total amount with accumulations would bring the total in the fund to March 31st, 1908, up to £196,741, as compared with the present amount of £158,622, so there is a shortage of £38,119. Allowing, however, for the amount of £34,634 transferred to the general reserve fund, the shortage is reduced to £3,485. £142,000 of the fund has been invested—£122,900 in L.C.C. stock and £20,000 in National War Loan. The market value of these investments on March 31st, 1908, was £140,482.

Tramway Proposals for 1909.

The Highways Committee have presented their annual report with regard to new tramways for which powers should be sought in the next session of Parliament. This deals with the matter under two heads :—(1) Schemes designed to facilitate the electrification of certain routes which still continue to be worked by horse traction owing to the width of the thoroughfares which they traverse being in parts insufficient for a double line of electric tramways; and (2) proposals for the construction of new tramways in extension of the existing system or for the purpose of connecting up detached portions of the tramways. The total estimated cost of constructing and equipping the proposed new lines is £403,430. The estimates are based on the use of conduit traction in each case, except as regards the proposed lines from Harrow Road to Edgware Road, *via* Sutherland Avenue, and from Wandsworth to Putney Bridge. This first-mentioned line, it is suggested, should be constructed for overhead traction, so that it may be worked in conjunction with the existing lines in Harrow Road which are already running on the same system, while the Wandsworth to Putney tramways will connect with the Hammersmith to Putney lines which it is proposed to construct on the overhead system The other tramways would, for the most part, be worked in close relationship with existing conduit routes, and for this reason it has been thought advisable to give the cost as for that system, as it would probably be economical from the point of view of working expenses and the convenience of the traffic not to introduce a fresh system. This, however, will not preclude the Council, should the schemes be authorised, from arranging, subject to the terms of the Act of Parliament, for the adoption of any other system if special circumstances make that course desirable.

Digitized by Google

(i.) *From Harrow Road*, via *Sutherland Avenue, to Maida Vale.*—Length of tramway, about 5 furlongs 5·5 chains. Estimated cost of construction and equipment for the overhead system of electric traction, £20,240. This tramway will connect the existing lines in Harrow Road, which are about to be purchased by the Council, with Edgware Road, and represents an instalment of other lines for which legislation will be promoted in a subsequent session.

(ii.) *From the existing tramways in Farringdon Road*, via *that thoroughfare, to a point opposite the north side of Charterhouse Street.*—Length of tramway, about 2 furlongs 4 chains of double line. Estimated cost of construction and equipment, for the conduit system of electric traction, £21,470. This is an extension beyond the present terminus of the horse tramways now running between King's Cross and a point near Farringdon Road station. It will take the tramways to a point adjoining the City boundary, and will be a considerable convenience to those desiring to reach the portion of the City adjacent to Holborn Viaduct and Snow Hill, and also to persons working in the meat market. A proposal for the electrification of lines as far as the terminus is under consideration.

(iii.) *From Mare Street* via *Victoria Park Road to Wick Road.*—Length of tramway, 1 mile 1 furlong 9 chains of double line, 3 chains of single line; total, 1 mile 2 furlongs 2 chains (route miles). Estimated cost of construction and equipment for the conduit system of electric traction, £54,890. This proposal will provide direct electric tramway communication between the densely-populated residential districts adjoining Victoria Park and the various City and West End termini of the Council's tramways *via* Hackney Road, Clerkenwell Road, &c.

(iv.) *From Essex Road*, via *Englefield Road and Stamford Road, to Kingsland Road.*—Length of tramway, about 5 furlongs 5 chains of single line. Estimated cost of construction and equipment for the conduit system of electric traction, £19,380. (iv*a*.) *Junction line between Kingsland Road and Dalston Lane*—Length of tramway, 1·6 chains of single line. Estimated cost of construction on the conduit system of electric traction, £650. (iv*b*.) *From Kingsland High Street*, via *Ridley Road and Dalston Lane to Amhurst Road*—Length of tramway, about 6 furlongs 3 chains of single line. Estimated cost of construction and equipment for the conduit system of electric traction, £23,800. These schemes together provide an alternative single line route of tramways to the existing lines in Essex Road, north of Englefield Road, Ball's Pond Road, Dalston Lane, and Graham Road to Mare Street. This route is at present worked by horse traction. The same proposals were included in the schemes for Parliamentary powers adopted by the Council in the years 1906 and 1907, but the Council was unsuccessful in obtaining the consent of the Hackney Metropolitan Borough Council to the introduction of a Bill to authorise them. It is hoped on the present occasion that the Council may be able to present the facts in such a way to the borough council as to obtain its consent to the scheme.

(v) *From New North Road* via *Shaftesbury Street and Shepherdess Walk, to City Road.*—Length of tramway 4 furlongs 2 chains of single line. Estimated cost of construction and equipment, on the underground conduit system of traction, £13,960. This tramway is intended to provide an alternative route to the portion of the existing tramways in East Road and New North Road, which lies between Shaftesbury Street and City Road. Between these two points the thoroughfares traversed by the lines are very narrow, and a considerable portion of the tramways consists of single line. To electrify this portion of the tramway as a double line would involve a very considerable outlay for street widenings.

(vi.) *From Battersea Park Road*, via *Battersea Bridge Road, Battersea Bridge and Beaufort Street, to King's Road.*—Length of tramways, 7 furlongs, 9 chains of double line. Estimated cost of construction, on the conduit system of electric traction, £59,850.

(vii.) *From Battersea Bridge* via *Cheyne Walk, Cremorne Road, Ashburnham Road, Tadema Road, Gunter Grove, Finborough Road, Warwick Road, and Holland Road to Uxbridge Road, with single line diversion* via *Edith Grove, Redcliffe Gardens and Richmond Road.*—Length of tramway, about 1 mile 7 furlongs 3 chains of double line, and 1 mile 5 furlongs, 7·5 chains of single line. Estimated cost of construction and equipment for the conduit system of electric traction, £135,470. The route suggested provides for single lines being constructed as alternative routes to each other, (1) from Cremorne Road *via* Edith Grove, Redcliffe Gardens, and Richmond Road, and (2) *via* Cremorne Road, Ashburnham Road, Tadema Road, Gunter Road, and Finborough Road, to the south end of Warwick Road. Throughout the remainder of the route a double line will be constructed along the main road. This route would connect up the Council's southern tramway system with the London United Tramways, which at present come to a dead end at Shepherd's Bush, and the portions of which within the county are purchasable by the Council in 1909.

(vii*a*.) *From Battersea Bridge* via *Cheyne Walk, Cremorne Road, Ashburnham Road, Tadema Road, Gunter Grove, Finborough Road, Warwick Road, and Holland Road to Uxbridge Road, with single line diversion* via *Ifield Road and Adrian Terrace.*—Alternative scheme to No. vii. above outlined, and provides for a double line throughout the main route, with the exception of a short distance in Ashburnham Road, where a single line will be laid. It is, however, suggested that a single line only should be laid in Finborough Road, between Fulham Road and Ifield Road, for dealing with the traffic in one direction, a single line being constructed along Ifield Road and Adrian Terrace for the traffic in the other direction. The cost of the construction and equipment of the tramways for the conduit system of electric traction will be about the same whichever route is adopted, although the cost of street widenings along the latter route will, we understand, be greater. Reference to this will no doubt be made in the report of the Improvements Committee.

The road authorities affected by the proposal, viz., Chelsea, Hammersmith, and Kensington Borough Councils, have not yet been consulted.

(viii.) *From York Road, Wandsworth*, via *High Street, Wandsworth, West Hill, Upper Richmond Road and High Street, Putney, to Putney Bridge, with single line diversions* (*a*) via *Buckhold Road, a new street between Buckhold Road and Broomhill Road, and Broomhill Road and* (*b*) via *Oxford Road and Putney Bridge Road.*—Length of tramway about 6 furlongs 5 chains of double line and 1 mile 4 furlongs of single line. Estimated cost of construction and equipment for the overhead system of electric traction, £53,740. This scheme provides for alternative single lines to portions of High Street, Wandsworth, and High Street, Putney, where the construction of a double line throughout would involve very expensive street widenings. The total length of line involved is 17 miles 1 furlong 3·1 chains, single line, and the total cost, £403,450.

Dealing with existing lines, the report recommends the reconstruction of portions of the London, Deptford, and Greenwich horse tramways from Tooley Street to Deptford, and proposes an extension to near London Bridge, and from Deptford to Greenwich; also with the reconstruction of the Highgate Hill cable tramways and a portion of the Woolwich and South East London tramways. These will all be dealt with upon the conduit system at a total cost of £297,850, the total length being 12 miles 1 furlong 8 chains single line.

A CRANE INSTALLATION WITH BATTERIES

WE have received from the D.P. Battery Co. some particulars of an installation at Southampton, where one of their storage batteries is used to equalise the load in connection with a series of electric cranes. These cranes take an average current of 250 amperes, at a line voltage of 500-525. The current fluctuations are necessarily severe with this type of work, and vary from 0 to 800 amperes. With the aid, however, of a battery and reversible booster, this load is very successfully dealt with by one 150 h.p. producer gas engine—another similar engine being in reserve. The engines are direct coupled to generators capable of an output of 192 amperes at 520 volts, with a 15 per cent. overload for half an hour. The coal consumption with the engines working at full load is 1·5 lb. per kw.-hour. The battery consists of 245 cells of the standard "L.S." 15-plate type, in wood lead-lined boxes, capable of discharging at 500 amperes for one hour, or at 1,000 amperes for short periods. The positive plates are about half an inch thick, and very solidly constructed to stand the heavy rates of charge and discharge. The formation of the plates is the "D.P." Battery Co.'s special Planté process, and consists of a thin hard skin, which is practically proof against disintegration—a very necessary qualification with a load such as the one in question. The cells are burnt up throughout, and the inter-row and terminal connections consist of 1 in. diameter copper rod. The battery is erected on single-tier stands, mounted on concrete blocks. The booster, made by the Lancashire Dynamo & Motor Co., is so adjusted that the engines can be set at any desired load, and all variations above or below this load are taken care of by the battery and booster. From the records taken at this station the value will be appreciated of the services rendered by the battery and reversible booster, as, with the line load fluctuating from zero to 800 amperes, the variation in the generator load is only about 15 amperes above and below the mean. The connections of the switchboard are so arranged that (1) the battery can be put into line by itself; (2) the battery and booster can take the load without the generators, the booster being adjusted so as to give an over-compounding effect; (3) the battery and booster can be put on the line in parallel with one or both engines, one engine being the normal running condition of things. In the unlikely event of both sets being temporarily disabled, the battery could keep all the cranes going for over three hours; thus the station is amply safeguarded against an interruption of supply. Besides the advantages in installing storage batteries, briefly alluded to above, a very considerable economy is effected in the size and first cost of the whole generating plant, in addition to the saving in daily working expenses and wear and tear of plant. The consulting engineers were Messrs. Lacey, Sillar, & Leigh.

ELECTROCHEMISTRY AND ELECTROMETALLURGY

IN the issue of the ELECTRICAL ENGINEERING of July 9th, we referred to an article by Frank B. Easterbrooks upon the Rartan Copper Works, which is, we believe, the largest electrolytic refining works in the world. Mr. Easterbrooks published the final part of this article in the July number of *Electrochemical and Metallurgical Industry*, this part of the article being devoted chiefly to the working up of the slimes and refining of bullion. The slimes are first screened through copper plates with one inch perforations, and then through a slotted copper screen equivalent to 40 mesh; by this means the bulk of the loose copper particles are removed. The slimes after this treatment are pumped from the tank-house to receiving tanks on the top of the slime room, centrifugal pumps lined with antimonial lead being employed. All overflow water and washing water which has been used for the washing of slimes in the filter press is returned to the tank-house. The slimes themselves are run from the receiving tanks into circular lead-lined tanks and boiled with sulphuric acid, sodium nitrate being added to hasten solution. Hard lead paddles containing 10 to 12 per cent. of antimony are rotated in the tanks, thus preventing the slimes from settling to the bottom in a solid mass. When the copper in the slimes is reduced to a very small quantity the mixture is transferred to an "egg," this being a lead-lined cast-iron vessel. From there they are forced by compressed air into a Bushnell filtering press where they are washed free from copper sulphate. Lead antimony alloy is used for the rings and plates of the press as it is found that copper or copper alloys become greatly attacked. The pressed slimes which are now in the form of cakes, are dropped from the press directly into trucks which run beneath it. They are then sampled, the amount of gold and silver being determined, weighed, and transferred to the furnace department. It should be mentioned that after the slimes have been screened, still from 8 to 18 per cent. of copper remains in them, and the boiling process with acid just referred to is to remove this copper. This gives an idea of the extremely fine state of division which is caused to the anode by electrolytic corrosion. Unfortunately the copper extraction by this method, although it occurs in the slimes in very minute particles, is very slow, and it is remarked that there is room for much research in order to devise an improved process to remove the copper. At present 10 to 15 days is required to ship the finished slimes as fine gold and silver calculating from the date they are received from the tank-house. In the furnace room the slimes are smelted, air being at the same time blown over the molten surface until they reach 98-99 gold+silver. Oil fuel is used in the furnace. Tellurium is one of the last impurities to be removed from the silver bullion, considerable loss of silver at the same time taking place. The refined bullion is cast by hand into thin plates, these forming the anodes for the electric parting plant. The cells used in the parting plant are constructed of white acid-proof stone ware, and the bottoms are lined with flat slabs of carbon carefully jointed together; these form the cathodes. The anodes are set slightly inclined from the horizontal, thus allowing solutions of heavy sp. gr. which are formed during electrolysis to more readily mix with the electrolyte below. The cathode contact pieces are made of fine silver, and last indefinitely. The anode contacts of bullion are made in specially constructed moulds, a threaded end being cast directly from the hot metal. The plant is so arranged that one aisle is used entirely for the removal of the deposited silver, and the adjoining one for the removal of the gold mud which remains upon the canvas tray placed beneath the anodes and over the cathodes. After drying and washing, the silver is melted down in a tilting crucible furnace; from this it is cast into bars weighing about one thousand troy ounces; the final product being 1,990 parts per thousand fine silver. The gold is melted down and refined as usual.

We understand that the Aluminium Corporation, Ltd., have every reason to be satisfied with their furnaces which were started some little time ago at Wallsend-on-Tyne, the quality of the metal produced never having fallen below 99 per cent. of the pure metal. Visitors to the Machinery Hall at the Franco-British Exhibition may see sample ingots in the exhibit of the Aluminium Corporation, Ltd. In connection with the furnaces, works for producing carbon electrodes have been erected which will be sufficient to supply the whole of the company's requirements, both at Wallsend and Dolgarrog. One of the three carbon electrode furnaces to be installed has already commenced operation. The company have also valuable bauxite properties in France in the Var district, and they are now mining the bauxite for the production of alumina. They have entered into arrangement with the United Alkali Co., of Newcastle-on-Tyne, who have works at Hebburn, close to Wallsend, to work up the crude material. To refine the bauxite a subsidiary company has been registered entitled the Bauxite Refining Company, three-quarters of the capital being held by the Aluminium Corporation, and the rest by the United Alkali Company. This subsidiary company will purchase bauxite at a fixed price from the Corporation, and will in return supply them with pure alumina. These bauxite refining works are very favourably situated from the point of view of cheap fuel, cheap power, and good transport facilities. In fact, it is claimed that alumina can be more cheaply produced here than at any other place in Great Britain. It is hoped that the alumina works will be ready to commence operations in January next, when it is expected employment for about 200 working people will be afforded. Owing to the great demand for aluminium sheets we understand that the Aluminium Corporation have lately included an agreement with an important firm on Teesside, in the neighbourhood of Middlesbrough, who will equip rolling mills in order to produce aluminium sheets, and also mills for the drawing of aluminium wires. The Welsh undertaking is stated to be progressing rapidly, and hopes are held out that operations may commence there in the autumn.

In *Electrochemical and Metallurgical Industry* of July, Mr. A. R. Betts, in the Correspondence Column, supplements the article by Mr. F. B. Croker, which appeared recently (ELECTRICAL ENGINEERING, Vol. III., page 635), upon diaphragms. Mr. Betts says that asbestos is the best all-round material available for diaphragms, the chief difficulty being to support the asbestos in the position it is required to occupy. He has successfully made diaphragms by forcing with moderate pressure, wads of moist asbestos into $\frac{5}{8}$ inch to 1 inch round holes bored in $\frac{5}{8}$ inch to $\frac{3}{4}$ inch boards. Another and probably better method is to place several thicknesses of asbestos paper between two perforated lead sheets, or perforated wood or rubber sheets, depending upon the nature of the solution with which the diaphragm is to be employed. The resistance of such a diaphragm made, *e.g.*, of 4 lb. lead perforated with $\frac{3}{8}$ holes, is practically negligible, and the lead does not ordinarily act as a metallic conductor. He says, however, that the best diaphragm for ordinary weak acid solutions, is made as follows. Powdered sulphur is evenly sifted over a $\frac{1}{4}$ inch asbestos mill-board, and heat is evenly applied an hour or so to the board at a temperature slightly higher than the melting point of sulphur. The operation is then repeated with the reverse side. Such diaphragms have a very good life.

ELECTRICAL SCIENCE

British and American

Susceptibility of Copper and Tin Alloys.—In the June *Physical Review* O. C. Clifford gives the results of a long series of measurements which had as their object the determination of the law connecting the magnetic susceptibility of copper-tin alloys with percentage composition. The apparatus used consisted of an electromagnet with the north pole vertically over the south pole, and with both poles bored by a central vertical hole. Through the hole in the upper pole the phosphor-bronze ribbon of a torsion pendulum passed and supported a disc of celluloid, which floated horizontally between the pole faces. The disc carried two small equal pieces of bismuth placed symmetrically. Four small iron pegs, two in each pole face, concentrated the magnetic field at the two symmetrically-placed points, where the bismuth rested when no field was on and when there was no torsion in the phosphor-bronze suspension, and, therefore, when the field was thrown on the bismuth was repelled from its zero position through an angle which was measured by mirror, scale, and telescope. The specimens of copper-zinc alloys to be tested were all the same size and shape, and were laid on the bismuth pieces on the suspended celluloid ring. There was an increase or a decrease of deflection, according as the added specimen was diamagnetic or paramagnetic. The tin used in the making of the alloy was specially purified for these experiments. Its susceptibility was found to be $+0{\cdot}31\times10^{-6}$; that is, it was very slightly paramagnetic and not diamagnetic, as Faraday found it in 1845. Probably there was still a slight iron contamination. The copper was native, and gave a susceptibility of $-1{\cdot}88\times10^{-6}$. Seven alloys were made and examined. As the proportion of tin increases from zero the negative susceptibility increases till a maximum is reached, when the tin is by volume one-third of the volume of the alloy. This is the alloy known as speculum metal; the susceptibility is

Digitized by Google

about $-2{\cdot}1\times10^{-6}$. The author gives his full results in the form of tables. These tables include the determinations made with magnetic fields varying from 250 to 700 C.G.S. units.

Continental

Electric Fatigue of Metals.—Some six years ago Dr. Jagadis Chunder Bose, of Calcutta, described an effect which closely resembles the fatigue observed in animal and vegetable tissues. When a wire, immersed in an electrolyte, is suddenly twisted, it sends an instantaneous current through a galvanometer. Repeated twistings show a gradual diminution of the current, but after a period of rest it recovers. A good deal of light is thrown on this curious phenomena by the Papers which appear in the *Comptes Rendus* for July 6th. One of them is by E. Guillaume, and the other by Jean Perrin, both well-known experimenters. The former finds that the effect is not observed when the wire is perfectly clean. An oxidisable wire shows it as soon as a thin layer of oxide is formed. A silver or platinum wire may also be made to show it by covering it with a thin porous coating of non-conducting material, such as silver, oxide, kaolin, or gelatine. The amount and sign of the effect may be predicted from the rules of electric osmosis. Perrin supposes that a thick electric double layer forms inside the porous film, and that ions of one sign are squeezed out by the torsion, thus giving rise to a p.d. and a momentary current. The process cannot be compared to the process of vital fatigue.

Stability of the Arc.—C. E. Guye and A. Bron have investigated the connection between the period of extinction of the metallic arc and the kind of metal employed for the electrodes. In the *Comptes Rendus* for July 6th, they announce an interesting relation which appears to exist betwen the p.d. and the atomic weight of the metals. The effective p.d. required to keep an alternating arc steadily burning is the higher the greater the atomic weight of the metal. With a current of 0·04 effective amperes, it ranges from 640 for carbon (atomic weight 12), 700 for magnesium (24), 850 for iron and nickel (56, 59) to 1,000 volts for platinum (194), and 1,070 for gold (197), the length of arc being 5 mm. In cadmium, which gives off thick vapours, the p.d. is exceptionally small, being only 725 effective volts with an atomic weight of 111. This is the only exception however. Two explanations suggest themselves. According to Dulong and Petit, the specific heat varies inversely as the atomic weight. Hence the heavier metals are cooled down more rapidly and have longer periods of extinction. Re-lighting is, therefore, more difficult. Also, if the vapour to be ionised is heavier, the ionising velocities of the electrons projected from the cathode must be greater, *i.e.*, its temperature must be higher.

More about Positive Electrons.—In the *Comptes Rendus* for July 13th. Jean Besquerel anticipates some criticisms likely to be passed on his alleged discovery of positive electrons in the free state. The easily deflected positive beam which he has observed is not identical with the beam of canal rays from which they emerge. If the willemite screen is connected with the cathode a new patch appears on it, which is only slightly deflected by a magnet. This is the original canal ray beam which the rearrangement of the field enables to travel the whole length of the three tubes. The easily deflected beam is not affected in any manner by the charge of the willemite screen. Its latter end appears to be totally unelectrified. The author appears to consider this as evidence that positive and negative electrons re-combine to form some new species of matters, perhaps identical with Righi's "magnetic rays" or even with hydrogen. But at first sight the facts seem to be covered by supposing that the undeflected beam simply consists of X-rays generated at the second cathode, which acts as an "anti-cathode." The author successfully meets the argument that the deviation of the positive beam is produced by a strong electrostatic field. The principal and secondary cathode beams may be independently deflected by two different magnets.

Lighting of Victoria Embankment.—The Highways Committee recommend that the gas-driven electric generating station upon the Victoria Embankment, which is used for the lighting of that thoroughfare, shall be abandoned in favour of a supply from the Charing Cross, West End & City Electricity Supply Co. at 1d. per unit, which will be reduced to 0·95d. per unit at the end of four years, provided the Council agrees to enter into agreement to take a supply for eight years. The difficulty arising from the fact that the Embankment is in the area of several electric lighting companies is got over by the circumstance that the distributing mains now laid for the lighting are the property of the Council, and the electric lighting company will give a supply to the Council's sub-station, from whence it will be distributed by the Council. It is stated that a saving will be made in the cost of lighting the Embankment, whilst the building now occupied by the generating station will be partly utilised as a sub-station for distributing the current, and partly for offices and accommodation for the staff of the electrical branch of the chief engineer's department, now housed in Cranbourne Street.

CATALOGUES AND PAMPHLETS RECEIVED

TESTING INSTRUMENTS & ACCESSORIES.—Messrs. Siemens Brothers & Co., of 12 Queen Anne's Gate, have just issued a very complete and profusely illustrated catalogue of testing instruments and apparatus for use with the same. The apparatus listed includes laboratory and portable moving coil instruments, dynamometer instruments, measuring transformers, Ferraris and electro-magnetic instruments, galvanometers, ohmmeters, resistance boxes, standards, testing sets, condensers, apparatus for testing iron losses, photometers, and other instruments and accessories. The following deserve special mention :—A direct-reading wattmeter, provided with two current ranges up to 200 amperes, and three pressure ranges up to 750 volts, for three-phase circuits, with unequally loaded branches.—A portable current transformer for enabling the current flowing in a single a.c. conductor, to be measured without the necessity of breaking the circuit. This consists of an iron core, the two halves of which can be unscrewed and clamped over the bare or insulated conductor. The secondary coil must be connected to an electro-magnetic ammeter, which should be calibrated with the transformer.—An apparatus for measuring the resistance of rail joints of electric railways by comparing the pressure drop across the joint against that in a given length of rail.—A portable induction bridge for measuring induction constants and the losses in inductive circuits. Large coefficients of self-induction down to about 10^{-3} Henry can be measured with this instrument.—A portable testing set for street use, consisting of a battery of 105 dry cells, and the necessary apparatus for measuring insulation, resistance, and capacity. The case is provided with shoulder-straps and collapsible legs, and weighs only 70 lb. complete, so that it can be carried by one man.—A collapsible photometer with self-contained ammeter and voltmeter, for continuous- or alternating-currents, and a Siemens-Bunsen silver-spot screen. Candle-power current, pressure, and energy consumption can be measured with this apparatus, which can be fitted with standard lamps of all powers.

CONDUIT FITTINGS.—The latest "progress sheet" from Simplex Conduits, Ltd., describes a new porcelain interior for conduit joint boxes, &c. This may be used either for making a tee or branch connection for flexible cord or fittings wire to light. The diameter permits of its being used with the standard Simplex switch ceiling rose or plug box, or circular junction boxes. The two brass contacts, which are separated by a stout porcelain fillet, have vertical saw cuts and an external thread; the insulation of the main wire is bared back sufficiently to allow it to be inserted in the vertical cut, and is then clamped down by means of a brass ring, having a female thread. The flexible cord or branch wire is treated in the same way and clamped down by a further ring. Connection can be made without cutting the main wire, ensuring good electrical contact. Some new cheap brass brackets are also illustrated on the same sheet.

VOLTMETERS.—A leaflet is to hand from the Hart Accumulator Co., of Stratford, describing their cell testing voltmeters. The scale is divided into tenths of a volt, and reads 3 volts either way, with zero in the centre. The resistance is high, enabling accurate testing. The pointer is made to point towards the positive terminal, so that the polarity may be easily determined.

SMALL TRANSFORMERS FOR METAL FILAMENT LAMPS.—The Foster Arc Lamp & Engineering Co., of Wimbledon, have issued a new list of auto-transformers for metal filament lamps. These are standardised in a very large number of sizes for secondary voltages of 25, 50, 60, 75, 80, 100, 110, 115 volts, and frequencies of 25, 40, 50, 60, 70, 75, 80, 83, 90, and 100 cycles per secondary current, varying from 4 to 100 amperes. The company claim to be the largest manufacturers of this class of apparatus. An example is worked out and given in the list showing the enormous saving that can be obtained with this system of lighting which, in the particular case taken, amounts to 71½ per cent.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published July 23rd, 1908

A full list of these was published in our last issue. The following are abstracts of the more important specifications.

Names in brackets indicate communicators of inventions from abroad.

1907 Patents

15,262. **Motor Starting and Controlling Switch.** BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). A motor switch, with the starting and speed varying arms so interlocked that the motor cannot be started up unless the field resistance is short-circuited. The field resistance also cannot be inserted until all the armature resistance is cut out. A no-voltage release is provided. Three claims, four figures.

24,138. **"Jandus" Enclosed Flame Arc Lamp.** A. D. JONES. This specification describes the particular arrangement of inner and outer globes, and the air-tight fixtures adopted in the construction of the "Jandus" enclosed flame arc lamp described in ELECTRICAL ENGINEERING, Vol. III., p. 299. An abstract of the specification, giving the composition of the salts carried by the positive electrode in this lamp, was given on page 365 of ELECTRICAL ENGINEERING, Vol. III. The arrangement described in the present specification permits of the withdrawal of the inner cylinder and lower (positive) carbon without the removal of the outer globe. Three claims, one figure.

24,707. **Manufacture of Metal Filaments.** BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). One method of increasing the specific resistance of a metal is to add to it a small quantity of another metal. The increase in resistance is generally accompanied by a lowering of the melting point, and this is particularly the case with tungsten and other difficultly fusible metals. The addition of a small amount of silicon to tungsten, however, raises the specific resistance to three or four times the original value without seriously lowering the melting point. According to this invention, silicon, produced by the reduction of silica in the electric furnace, is powdered and mixed with powdered tungsten in the proportion of 5 per cent. of silicon to 95 per cent. of tungsten. The mixture is bound with an alloy of equal parts of cadmium and mercury, and squirted through a diamond die at a temperature of about 150° C. The resulting filaments are baked and then sintered, so that the final filament consists of tungsten and silicon only, possibly in some chemical combination. Such filaments are said to have a specific resistance three or four times as high as pure tungsten filaments, and yet a fusing temperature and an operating efficiency substantially the same as that of the pure tungsten filament. Three claims, no figures.

26,642. **Protective Device for High-tension Systems.** E. L. CREIGHTON. The usual spark-gap connected between a line conductor and ground will relieve the line of any charge producing a potential higher than that necessary to overcome the resistance of the gap. Once the gap resistance is broken down, however, an arc is established, and there is practically no resistance to the flow of line current. This invention consists in employing a spark-gap, in which at least one of the terminals is an electrolyte. The difficulty of maintaining an arc with an electrolyte as a cathode is so great, that so long as the line voltage is less than about 1,500 volts, the arc is extinguished directly the lightning or other high-potential charge has gone to earth. For line pressures higher than 1,500 volts, a number of such gaps in series must be used. The gap is constructed as a cell containing a solution of potassium and sodium carbonates. The two copper electrodes, which project downwards to within a short distance from the surface of the electrolyte, are separated by a partition extending below the surface of the electrolyte. An ordinary spark gap in series with a battery of such cells, prevents any continuous leakage to earth over the surfaces of the cells. Experiments have shown that the discharge through such cells, due to a rise of potential, never lasts for more than a fraction of a half-cycle. A modified form of cell has no metal electrodes, the discharge taking place between two electrolytes. Four claims, thirteen figures.

1908 Patent

5,279. **"Liconite" Insulating and Impregnating Compositions.** E. S. ALI-COHEN. An insulating material described in specification No. 8,071 of 1902, consists of a mixture of purified asphalte and petroleum in proportions varying between 70 : 30 and 40 : 60 per cent. respectively, according to the consistency required. The asphalte is previously heated for a long period at a temperature of about 160° C.; and then the petroleum, a solution of aluminium aceticum, some colophony, and an alkali are added. According to this specification the hard jet-black product, produced as above, is mixed with a vegetable oil such as castor oil, linseed oil, colza oil, or wood oil. The oil is first dried, and then oxidised by boiling with from one to three per cent. of peroxide of manganese. The mixture of oil and petroleum-asphalte compound is heated, cooled down, and a vulcanising agent, such as sulphur, added; it is then reheated to effect vulcanisation. The product is passed through heated rollers and then resembles vulcanised india-rubber, being strong, elastic, and impervious to water. In this state it is suitable for the insulation of high-tension cables. To produce an impregnating liquid, the above mixture, of the previously patented composition and a vegetable oil, is not vulcanised, but is mixed with benzine or some other solvent. Five claims, no figures. (Some high voltage tests, on some cables insulated with the elastic material and also tests on paper-cables impregnated with the impregnating liquid, were described in ELECTRICAL ENGINEERING, Vol. III., p. 803.)

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.

Summaries of the more important of these patents will appear in our next issue.

1907 Patents

8,079, LEONARD. Control of electric motors.
12,967, RORKE & RORKE. Switch.
13,206, ARTHUR. Controlling system for electric railways.
15,634, EBERT. Control of electrical devices.
15,789, EDGAR. Telegraphic receiving instruments.
15,798, KUZEL. Metal filament lamp.
15,830, FENNELL & PERRY. Mould for casting accumulator grids.
16,034, THOMSON. Pocket electric lamp.
16,067, RAMSAY. Manufacture of nitric acid.
16,068, RAMSAY. Manufacture of oxides of nitrogen.
16,073, WILLIS (*Waring*). Electrically-operated cloth-cutting machines.
16,137, ALLGEMEINE ELEKTRICITÄTS GES. Signalling systems.
16,175, MORGAN CRUCIBLE CO., & MCCOURT. Means for attaching flexible conductors to commutator brushes.
16,431, STEARN & TOPHAM. Electric incandescent lamps.
17,817, HYDE. Joints in metal filament lamps.
18,661, GILFILLAN. Brake for tram cars.
20,919, BELL. Magneto ignition machines.
21,127, OLDFIELD & OLDFIELD. Anti-vibration device for the electric lamps of automobiles.
21,363, RAWORTH & RAWORTH. Motor control.
23,116, RAILING, SOLOMON, & CROCKER. Metal-cored flame arc-lamp carbons.
23,318, HARTMANN & BRAUN AKT.-GES. Magneto machines.
23,768, SIEMENS BROS. & CO. & GRIMSTON. Electrically-controlled compasses.
28,530, MATHER & PLATT, LTD. (*Rosenberg*). Motor generators.
28,738, EBNER. Electrical ignition devices.

1908 Patents

3,507, PASSBURG. Vacuum drying and impregnating apparatus for electric cables.
5,107, SCOTT. Regulation of electrically-driven fluid compressors.
6,737, FELTEN & GUILLEAUME LAHMEYERWERKE AKT.-GES. Non-inductive resistances.
6,895, SIEMENS & HALSKE AKT.-GES. Electric meters.
7,480, SIEMENS & HALSKE AKT.-GES. Method of testing electrolytic valve cells.
8,065, CROMPTON & CO., MACFARLANE, & BURGE. Rotary transformers or motor generators.
9,849, BOULT (*Union Switch and Signal Co.*). Electric signalling systems for railroads.
10,121, ALLGEMEINE ELEKTRICITÄTS GES. Dynamo commutator machines.
11,524, SIEMENS & HALSKE AKT.-GES. Manufacture of metal filaments free from carbon.
12,097, RORKE & RORKE. Make and break devices.

Complete Specifications open to Public Inspection before Acceptance.

1908 Patents

11,221, SCHERL. Single track vehicles.
12,656, TIMAR & VON DREGER. Arc lamps.
14,048, SIEMENS-SCHUCKERTWERKE-GES. Overhead electric traction systems.
14,093, BARADUC-MULLER. Metallurgical process.
14,483, MARETTI. Process for rapidly mounting metal filaments in electric lamps.

Expiring Patent

The following patent expires during the current week after a life of fourteen years :—

14,988, of August 4th, 1894. **Electrolytic Cell.** E. SOLWAY. The liquid to be electrolysed flows over a rotating surface which is composed of the edges of a number of strips of platinum alternately positive and negative and insulated from each other. The roughened surface diminishes surface or capillary adhesion. A construction of cell which also enables the evolved gases to be collected separately is described.

LOCAL NOTES

ABERDEEN: *Tramways Accounts.*—The total revenue from the Corporation tramway system for the year ended May 31st, 1908, was £71.931, a decrease of £675 compared with the receipts of the previous year. It should be explained, however, that the receipts for 1907 show an abnormal increase of £14,000, due to the visit of the King and Queen. The working expenses were £38,669, a decrease of £1,765, whilst the car mileage run has increased by 36,437 miles, giving a decrease in the working expenses of nearly ½d. per car mile. Capital charges amount to £18,341, a decrease of £406, which is brought about owing to 16 days' interest for the current year having been paid in the last accounts. The balance amounts to £14,920, an increase of £1.497, which has been carried to renewals fund, and is the largest which has yet been available. The quantity of electrical energy used was 1,955,858 units, an increase of 49,640, whilst the car miles run were 1,566,118, an increase of 36,437. The cost of electrical energy has decreased by £389 owing to a rebate in the price charged by the electricity department. During the year six additional cars have been provided with top covers and magnetic slipper brakes. The receipts per car mile were 11·02d., and the working expenses 5·93d. The percentage of working expenses to receipts is 53·75.

ARGENTINE: *Buenos Ayres Tramway Returns.*—A Consular report states that there are now 327 miles of electric tramways in Buenos Ayres and 11 miles of horse tramways. The number of passengers carried in 1907 upon the electric tramways was 21,770,000 and upon the horse tramways 7,388,000. The total receipts from both electric and horse tramways in 1907 amounted to £1,986,100.

Telegraph System.—There are now 15,535 miles of telegraph lines in Buenos Ayres. The total revenue in 1907 from the post and telegraphs amounted to £862,631, whilst the expenditure was £1,015,790.

AUSTRALIA: *Sydney Tramway Strike.*—The employees on the tramway system struck work on Thursday, some 3,000 men being involved. A later telegraphic message states that all the tramway strikers have been officially dismissed. The Premier has stated that the Government will not appoint a proposed special tribunal to hear the men's grievances until they have returned to the work.

BARNES: *London Electric Power Bills.*—The Parliamentary Committee recommend continued opposition to these Bills. It was stated at the last meeting that £150 have been spent in opposition to one Bill and £115 in opposition to the second Bill. When the Council first decided to oppose these Bills the sum of £250 was allowed for expenditure, and complaint was made that the expenditure seemed to be going on much in excess of the estimates before the Council.

BELFAST: *Lighthouse Communication.*—The Belfast Harbour Board has had under consideration the question of telephonic communication with the lighthouse at Blackhead, Copeland Islands and St. John's Point. The matter has been referred to the Irish Lights Board.

Halfpenny Tramway Fares.—The experiments with halfpenny tram fares during the trial fortnight decided upon by the Corporation shows a decrease in receipts compared with the corresponding period of last year of £1,350, or over 15 per cent. A good deal of controversy is taking place as to the system of fares which should be adopted in order to place the undertaking on a sound financial basis. A scheme proposed by Mr. A. Nance, the manager, in 1905, is now to be given a trial. This proposes a 2d. fare for the full journey over any route, with 1d. stages.

BRENTFORD: *Condition of Tramway Track.*—The Brentford District Council has received a copy of the report made to the Board of Trade by Col. Yorke on his inspection of the tramway track, expressing the opinion that the condition of the track was a source of inconvenience to the ordinary traffic, and of possible danger to motor-cars and bicycles. It was, therefore, his duty to report that in his opinion "there has been default in maintaining and keeping in good condition and repair, and so as not to be a danger or annoyance to ordinary traffic the rails of the tramway and the substructure." However, Col. Yorke added that there were evidences that extensive repairs had been, and were being, carried out, and he recommended that the company should take steps to put the whole of the portion of their system in question in proper condition with as little delay as possible. The District Council has decided to ask the company to give an undertaking to take steps to put the whole of their system in the district in order and repair, and at the last meeting of the authority the Clerk said that if the company would not give the undertaking they could be prosecuted for penalties.

BRISTOL: *Electricity Accounts.*—The report and accounts for the electricity department for the year ended March 25th, 1908, show a gross profit of £43,126, to which is added £855 interest and £129 transferred from redemption sinking fund account. Capital charges, reserve, &c., absorb £43,637, leaving a net profit of £473. This latter sum, together with £8,657 brought forward from the last account, has been carried forward, minus £2,150, which has been carried to the credit of capital account, in respect of wages of workmen engaged on capital work, owing to the work being carried out by workmen in the permanent employ of the committee. The number of units sold was 7,650, 074, of which 3,088,055 were for private lighting, 3,718,296 for power purposes, and 843,773 for public lighting. This is an increase of 1,231,928 over the output of the previous year, whilst the units for power purposes had increased to no less than 1,098,466.

BUENOS AYRES: *Electric Supply.*—It is stated that the accounts of the German Transatlantic Electricity Co., for 1907, show a profit of M9,955,000, against M8,278,000 in 1906. A dividend of 9½ per cent. has been declared.

CARDIFF: *Tramway Men's Wages.*—The Electric Lighting and Tramways Committee have had under consideration a request by the tramway employees for increased pay and modified hours. Mr. Arthur Ellis, the tramways manager, reported that if the committee granted the increases asked for he should have to ask the committee that the tramway men be brought into line with those upon other tramway systems as to the conditions of their employment, namely, that 60 hours per week be worked, that ordinary rates be paid on Sundays, and no double time paid for Bank Holidays. He also suggested that it would be necessary to charge higher fares if the tramway men's demands were acceded to. A further special meeting is to be held to consider the position.

COATBRIDGE: *Electrical Inspector.*—The Council has been considering the question of appointing an electrical inspector under the Electric Lighting Acts, to advise them on all matters appertaining to the supply of electricity in the district by the Coatbridge & Airdrie Electricity Supply Co. Several offers have been made by gentlemen willing to act in this capacity, but their fees have averaged from £50 to £100. At a recent meeting of the Council the view was expressed that these gentlemen regard the office as a more important one than the Electric Lighting Committee did, and the matter is left for the moment in the hands of the committee.

DEVONPORT: *Electricity Accounts.*—The gross profit upon the electricity undertaking for the past year amounted to £6,790, against £9.055 for the previous year. This decrease is mainly due to the extra cost of coal (£830), and a decrease in the revenue from sale of electricity (£1,000); this latter has been brought about by decreased prices, the use of metal filament lamps, and the requirements of the tramways companies having been less. The net profit was just under £7, compared with £2,480 in the previous year.

EDINBURGH: *Electric Lighting Estimates.*—The Electric Lighting Committee have estimated that the expenditure for the current financial year will be £65,900, against £60,040 last year. The estimated revenue is put at £131,360, against an estimated revenue last year of £132,585, and an actual revenue of £129,691.

Electric Lighting Surplus.—The Electric Lighting Committee have been considering the question of the best manner in which to dispose of the surplus of £10,541 upon the electric supply undertaking for the past year. It was unanimously agreed to carry £747 to reserve, bringing this up to £97,940. Several suggestions were made with regard to the disposal of the balance of £9,794, and the one to the effect that the whole should be allocated to the relief of rates was carried. This has yet to be confirmed by the Corporation.

EPSOM: *Cost of Cables and Services.*—The Lighting Committee having considered the question of defraying any expenditure incurred, or to be incurred, in respect of cable extensions and services which is properly chargeable to capital account and temporarily paid out of revenue account, the accountant has been directed to place such expenditure to a suspense account pending the raising of a £1,500 loan.

FRANCE: *Calais Electric Tramways.*—A British Consular report states that the system of electric tram lines, of which Calais has so long been in need, being many years behind the much more hilly town of Boulogne in this respect, is being rapidly pushed on, and is expected to be opened for traffic coincidentally with the inauguration of the Calais Exhibition.

Dieppe: Wireless Telegraphy.—A Consular report states that the Artom experimental wireless telegraph station between Havre and Barfleur has given disappointing results, but that experiments with the Bellini & Tosi system have been very encouraging.

GREENOCK: *Admiralty Supply.*—The Electricity Committee have been negotiating with the Admiralty with regard to the supply of electricity to the proposed torpedo factory, which is to be erected at Battery Park. Among the proposals provisionally accepted by both parties is that the Admiralty agree to take the whole of the electrical energy required for power and lighting purposes at the new torpedo factory for a period of 14 years at certain rates, with proportionate allowances in the event of a general reduction of price. It is further stipulated that the Corporation shall supply a maximum of 200 kw., but that the Admiralty shall give six months previous notice of any

Digitized by Google

appreciable increase in its maximum demand. It is expected that the supply will be required in about 18 months.

HENDON: *Experimental Street Lighting.*—An offer of the Hendon Electric Supply Co., Ltd., to fix two specimen lamps in positions in the public streets to be selected by the District Council to demonstrate the advantages of electricity for public lighting, has been accepted. The lamps are to be fixed free of cost to the Council.

HINDLEY: *Provision Order Extension.*—The Council have obtained an extension of their Lighting Order for a further twelve months.

LIVERPOOL: *Tramway Fares.*—A report has been submitted by the tramways manager dealing with the question of free conveyance of blind persons upon the tramway system. The Finance and Traffic Sub-Committee, however, report that they cannot recommend charity as a basis of administration of the tramway undertaking, and this decision was confirmed at the fortnightly meeting of the Tramways Committee last week.

LONDON: *London County Council: Norwood Car Shed.*—A site of approximately two acres has been acquired for the purpose of a car shed at Norwood by the Highways Committee at £7,750.

Marylebone: Assessment of Electricity Undertaking.—The Local Government, Records, and Museums Committee of the London County Council, in a report upon the assessment of the electricity undertaking of the Marylebone Borough Council, state that the present assessment of £7,547 is quite inadequate, based upon the accounts for 1906–7, and that an estimate, which had been prepared by taking the revenue from the sale of current on the basis of the average of the prices obtained during 1906–7 by other undertakings in the neighbourhood, showed that the rateable value should be £57,391. In view of these facts they had requested the Assessment Committee to re-value the undertaking at once. They complain, however, that nothing has been done to put this recommendation into effect, although the accounts for the year ended March 31st, 1907, have been available many months. Having regard to the very great importance of this case, the Local Government, Records, and Museums Committee state that they thought it desirable to place the facts before the committee.

Islington: Supply of Electricity Bill.—Messrs. Vorley & Lambert have been appointed delegates to represent Islington upon a deputation from metropolitan local authorities urging the President of the Board of Trade to re-introduce the Supply of Electricity Bill.

Southwark: Electricity Accounts.—In his report on the working of the Borough Council electricity department for the year ended March 31st (the eighth year the works have been in operation), the Borough Electrical Engineer (Mr. D. M. Kinghorn) remarks that the most noticeable feature of the accounts is reduction in the net profit, which is accounted for by the increased cost of coal, but if future profits are to be greater some immediate steps should be taken to reduce the expenditure in this direction, as it is scarcely possible to do so with the plant running non-condensing. Economies have been effected in the other costs, but as coal forms about 40 per cent. of the combined works costs, a variation of one-tenth of a penny will affect the net profit to the extent of £584. Further capital expenditure will be necessary, but considering the possible economies effected any reasonable expenditure will not unduly burden the undertaking. The total working expenses for the year (£9,667) exceeded the amount for the previous twelve months by £1,232, the expenditure for coal having increased in nearly the same proportion as the units generated. The total distributing cost compares very favourably with former years. Public lighting maintenance increased by £73, owing to the flame lamp having superseded the old open arc, excepting on one circuit. The total income for the year amounted to £14,932, showing an increase over that of the preceding year of £1,220, and the number of units sold increased 17 per cent. The units sold for lighting purposes increased by 123,948, which, says the engineer, may be considered a satisfactory increase, in view of the great improvement made during the last two years in the metal filament lamp. The average price was 3·1d. per unit, compared with 3·49d. per unit last year. The units sold for power purposes increased by 30 per cent., the average price obtained being 1·37d. per unit, the same as the previous year. The gross profit carried to net revenue account is practically the same as the previous year, amounting to £5,265, representing a return of 6·6 per cent. on the total capital expenditure. The total capital charges are now equal to 0·877d. per unit sold, comparing very favourably with other metropolitan undertakings, the decrease for the year being approximately 10 per cent. compared with the previous year.

Stoke Newington: Tramways.—The Borough Council has decided to call upon the London County Council to at once put in hand the electrification of the Green Lanes tramway line.

Woolwich: Tramway Extension.—Col. Yorke on Friday inspected the new tramway line which has been built by the London County Council from Plumstead Church to Abbey Wood. This line joins the Erith Urban District Council's Tramway system, thus making it possible to travel by tramway from the Victoria Embankment some 12 or 14 miles into Kent, almost to Gravesend.

MANCHESTER: *Tramway Accounts.*—The annual report and accounts of the Corporation Tramways Department show a traffic revenue of £760,994, parcels revenue of £1,220, and revenue from other sources, £6,858. The working expenses amounted to £500,022, leaving a gross balance of £269,049, to which has to be added £2,105 bank interest. Capital charges, &c., absorb £124,255, and the balance has been appropriated as follows: reserve, renewals and depreciation, £87,790; contribution in aid of rates, £55,000; street improvements, &c., £4,108. The quantity of electrical energy used was 29,955,070 units, representing 1·76d. per car mile. The percentage of working expenses to receipts was 65, and the total revenue per car mile was 10·87d.

MIDDLESEX: *Tramways.*—At the last meeting of the County Council it was reported that the work included in the contract for Edgware Road Tramways extension has been completed by Mr. Clift Ford. The contract price was £5,886, and when the balance of the retention money has been paid to the contractor the contract price will have been exceeded by £1,336 for extras. The County Council agreed to this. Mr. Clift Ford has also completed the work included in the contract for the Harrow Road, Wembley, tramway. When the retention money has been paid the contract price will have been exceeded by £1,896 5s. 3d. This amount is made up of extras, *i.e.*, the substitution of granite setts for wood blocks on the double track. The Council agreed to the excess. After the payment of retention money to Messrs. Dick, Kerr & Co., the estimated cost of the Jubilee Clock to Willesden Junction tramway, which work has been completed under a schedule of prices, will have been exceeded by £2,037. This amount, which the Council agreed to, is made up of extras for the construction of junction line at Jubilee Clock tower and the paving of the haunches of the roads with wood blocks.

NEWCASTLE: *Blaydon Tramways.*—A deputation from the Blaydon Urban District Council waited upon the Newcastle Tramways Committee last week, urging the extension of the Newcastle tramways into Blaydon. A long discussion took place, and at the conclusion the Chairman stated that the matter would be very carefully considered by the Tramways Committee, but at the same time he thought there was at the present no prospect of surmounting the many difficulties that had been mentioned during the discussion.

NORWICH: *Electricity Accounts.*—The accounts of the electricity undertaking for the year ended March 31st, 1908, show an income of £35,613 and an expenditure of £18,868. The charges for interest and sinking fund have increased by £16,080 over those for the previous year, and there remains a net profit of £3,104, to which is added £195 brought forward from the previous year. The sum of £3,200 has been placed to depreciation and the balance carried forward. The depreciation account now stands at £15,905. There has been an increase in the number of units sold of 29 per cent., the figures for the present and past years being 2,839,130 and 2,661,522 respectively. There has also been an increase in the total income of £3,335, equal to 11 per cent., and it may be pointed out that new meters to the extent of £1,193 have been provided out of revenue. There are now 4,253 consumers, of which 291 have been connected during the year. The connections are equivalent to 129,171 8-c.p. lamps, and the aggregate h.p. of the 405 motors connected to the mains is 2,215. There has been a reduction in the total works costs of 0·15d. per unit, despite an increase in the cost of coal amounting to £800. The accounts were submitted at a meeting of the Corporation last week.

PONTYPRIDD: *Electric Lighting and Tramways Accounts.*—The accounts of the Electricity Department for the past year show a gross profit of £2,554, but after providing for capital charges there is a loss of £1,255, against £2,582 last year. Upon the tramway undertaking there is a gross profit of £4,081, but a deficit, after making capital charges, of £3,541.

ROSS: *Extension of Lighting Mains.*—The Ross Electric Light & Power Co. propose to apply for a provisional order to extend their mains in the Rural District. The Council, however, consider the area too large, and the question of consent has been adjourned until further information is received from the company.

RUSSIA: *Moscow: Telephones.*—A Consular report states that the Swedish-Danish-Russian Co., which has the monopoly for telephones in Moscow, some eight years ago had about 500 subscribers. At the present moment there are about 25,000, and the company is enlarging its premises so as to deal with 50,000. The present annual charges are:—Private telephone, 71 r. (£7 10s.); public telephone, 102 r. (£11); these prices apply within the two-verst radius. Outside of that the prices are raised.

SOUTHEND: *Tramway Extension.*—The tramway extension to the Halfway House towards Shoeburyness has now been commenced.

SOUTHPORT: *Electricity Accounts.*—The accounts of the electricity department for the year ended March 31st, 1908, show a revenue of £25,404, and an expenditure amounting to £9,836. Interest on loans, sinking fund, and dividends on redeemable stock absorb £11,734, leaving £3,834 net profit. Of

Digitized by Google

this, to which has to be added £311 balance from last year, £2,750 have been transferred in aid of rates, £496 to the renewals fund, and £90 to the motor-wagon account. The number of units sold was 2,104,259, of which 1,317,181 were to private consumers, 687,128 under contract, and 99,950 for public lamps, of which there are now 72. The total maximum demand supply demanded was 1,673 kw.

SWANAGE: *Electric Lighting.*—Messrs. Foote & Milne have notified the Council of their intention to apply to the Board of Trade for an electric lighting provisional order for the district.

SWANSEA: *The Telephone Service.*—Complaints having been made that the telephone service in Swansea since it has been taken over by the National Telephone Co. is much more inefficient than was the case during the period of competition between the company and the Corporation, Mr. W. E. Gauntlett, the district manager of the company, has given some figures of tests in order to prove that the general efficiency of the telephone system in Swansea at the present moment has greatly improved during the past twelve months, during which the company has acquired the Corporation system. For instance, he states that tests made by an officer entirely independent of the local operating staff, on a large number of calls in October, 1907, showed that the average time taken to answer a call was 4·4 seconds, and the time to clear after the ring off was 4·7 seconds, making a total time for the operation of 9·1 seconds. Comparative tests made in June of this year showed that the time to answer had been reduced to 3·6 seconds, and the time to clear after the ring off to 3·4 seconds, thus reducing the total time for the operation to 7 seconds.

TASMANIA: *Launceston Tramways.*—A local syndicate has been formed for the construction of tramways in Launceston. Tracks, where double, will be laid 10 ft. centre to centre and upon the standard gauge. Rails weighing 90 lb. to the yard on the straight and 96 lb. to the yard on the curve will be laid, the British Standard Specification being adopted. The rails are to be laid on sleepers in blue stone ballast. A combination type of car will be adopted, which was first designed by Messrs. Noyes Bros. for the Freemantle tramways; it has also been adopted by the Victorian Government for the Brighton-St. Kilda tramways.

TWICKENHAM: *Noisy Tramcars.*—The District Council has decided to call the attention of the Chief Commissioner of Police to the matter of noises arising from defective tramcars running through the district.

URUGUAY: *Electric Lighting.*—A Consular report states that the electric supply installation was completed a month or two back, but owing to some question between the municipality and the Government in connection with the cost it has not been put into use.

WALSALL: *Tramways Supply.*—The Council have agreed to the recommendation by the Electricity Committee that the South Staffordshire (Lessee) Tramway Co. be supplied with electricity at 1½d. per unit, less 10 per cent. discount, subject to revision every three years, and that the estimated cost of laying cables, &c., namely, £800, be paid by the Corporation.

Tramwaymen's Grievances.—After ascertaining by inquiry from 83 towns that in only 18 was extra pay allowed for Sunday work, and that in other respects the conditions of work in Walsall were more favourable than in other towns, the Tramways Committee report that they cannot comply with the men's request for time and a quarter on Sundays.

WALTHAMSTOW: *"Association" for Electric Supply.*—A reciprocal arrangement has been entered into with Leyton District Council to supply current at 1½d. per unit for the tramways in the event of a breakdown, and Leyton will supply current to Walthamstow, if necessary, at the same price.

WOLVERHAMPTON: *Electric Lighting Profits.*—The Electricity Committee report that £14,117 will be set aside out of the past year's profits to the Improvement Rate Fund.

YORK: *Trials of an Electrobus.*—We understand that an electrobus, similar to those which are now running in London, will shortly be running trial trips in the streets of York for the members of the Corporation and others interested in the opening out of the city and suburbs, with a view to establishing a service in York.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Miscellaneous

FRANCE.—A Consular Report states that there is an opening for small electric motors in the Amiens district.

LONDON: *London County Council.*—The Fire Brigade Committee report that metal filament lamps have been experimentally used at the Clerkenwell Fire Station, with the result that the consumption of energy has been considerably reduced, and the illumination nearly doubled. They accordingly propose that similar lamps shall be installed at the chief station of the brigade, and at the Shepherd's Bush, Bayswater, Kilburn, West Hampstead, Islington, Scotland Yard, and Whitefriars stations, upon which an estimated expenditure of £136 is recommended.

Generating Stations, Sub-stations, Mains, &c.

CORNWALL.—The Great Western Railway Co. invites tenders for the erection of an electricity generating station at Fowey, Cornwall. Particulars from the Engineer, Plymouth (North Road) Station, and tenders to the Secretary, at Paddington, by August 3rd.

FINCHLEY.—The Council invite tenders for the supply and erection of a generator panel and accessories, for 2,000 amperes. Full particulars from Mr. E. Calvert, Electrical Engineer to the Council (fee, £1 1s., returnable), and tenders to the Town Clerk by August 6th.

LONDON: *Battersea.*—The Highways Committee of the London County Council recommend the granting of a loan of £8,558 for electric lighting purposes; £733 of this is in respect of excess expenditure over loans already sanctioned. The rate of interest is £3 17s. 6d. per cent.

Hammersmith.—A loan of £10,000 in connection with the electricity works is to be applied for.

Shoreditch.—The Highways Committee of the London County Council recommend sanction to a loan of £4,365, repayable in 30 years at £3 17s. 6d. per cent., for electric lighting purposes. The committee also recommend sanction to a further loan of £7,000, repayable in five years, which is the approximate expenditure during the next few years, in connection with the change of pressure from 150 volts to 240 and 480 volts on the three-wire system.

Stepney.—A loan of £6,000 is recommended by the Highways Committee of the London County Council for extension of mains, repayable in thirty years.

Stoke Newington.—A loan of £3,148 is recommended by the Highways Committee of the London County Council for the erection and equipment of a generating station in connection with a dust destructor.

Woolwich.—Subject to the conversion of 13 lamps *en route* from gas to electricity, distribution mains are to be extended along the west side of Court Road, and a feeder is to be laid from Eltham High Street sub-station, at a cost not exceeding £2,000, including the provision of necessary switchgear at the station. In order to meet an application for current for power purposes, the Borough Electrical Engineer has been instructed to carry out extension of mains at an estimated cost of £1,820.

NETHERLANDS.—The Communal Council of Kattendijk (Zeeland) have granted provisionally, for one year, to Messrs. Barger & Co., of The Hague, a concession for constructing and working an electric installation for lighting and tramway traction.

TONBRIDGE.—A Local Government Board inquiry was held last week into an application by the Council for sanction to borrow £4,000 for extensions to the electricity works. There was some opposition on the part of the Ratepayers' Association. Mr. M. P. Plunkett, the Council's Electrical Engineer, stated that the £4,200 was made up as follows:—150-kw. steam dynamo, condenser, and spare armature, £966; steam and water pipes, £508; extension to switchboard, &c., £246; foundations and brickwork, £80; tools at works, £30; Lancashire boiler, &c., £540; extension to economiser, and alteration to brickwork, £120; steam and feed piping, £70; contingencies, £340; expenditure on mains, meters, &c., to March 31st, 1908, £412; future extensions of mains and other capital expenditure, £887.

WALSALL.—The Local Government Board has sanctioned a loan of £4,000 for extensions to the electrical undertaking.

WALTHAMSTOW.—Application is to be made to the Local Government Board for sanction to borrow £1,299 for mains extensions and house service connections.

WEST HAM.—A Local Government Board inquiry was held last week into an application by the Corporation for sanction to borrow £51,600 for the purposes of the electricity undertaking. The West Ham Municipal Alliance and the Forest Gate Ratepayers' Association both opposed the application, whilst Mr. E. Robb also opposed on behalf of the India-rubber, Gutta-percha & Telegraph Works Co., Ltd., on general grounds. This firm, he said, were large ratepayers, and last year contributed no less than £7,312 in rates. It came out in the inquiry that, included in the amount now sought, the sum of £13,566 represents excess expenditure over previous loans. Mr. Robb and the other objectors contended that the rates now charged in West Ham for electric supply are unremunerative, and certain specific contracts asked for were refused by the Corporation. A good deal of discussion took place on this point, and after Mr. A. H. Seabrook, the Electrical Engineer to the Corporation, had refused to give the prices charged in one specific instance, the inspector stated that they had apparently come to a deadlock, because if he did not know what prices were being charged, he did not see how they could get on with the inquiry. The inquiry, which had lasted two days, was thereupon adjourned *sine die*, the inspector remarking that

Digitized by Google

he would report to the Local Government Board that the Corporation could not supply him with the information.

WOLVERHAMPTON.—The scheme for lighting the Tettenhall Road district at a cost of £750 has been confirmed by the Corporation.

Wiring

LONDON.

N.W.—The St. Pancras Council have passed plans by the Skinners' Co. for the erection of business premises on the site of Nos. 45—113 Euston Road, inclusive.

Hospital for Invalid Gentlewomen in Lisson Grove. Architect, C. W. Herrier, 11 Waterloo Place, S.W.

Church rooms (£3,000), St. Stephen's Church, Hampstead (Rev. H. N. Bate, vicar).

S.E.—House at Southwood Road, Eltham. Hodgkinson & Son. architects, 22 Wellington Street, Strand, W.C.

Three blocks of buildings in Upper Kennington Lane. Architects, Hayward and Maynard, 14 John Street, Adelphi, W.C.

Deptford Borough Council have acquired sites for a central public library and a branch library. G. W. Preston, Town Clerk.

Extension to the Borough Polytechnic. W. M. Richardson, secretary.

Buildings in Rotherhithe for H. J. Enthoven & Sons, Ltd., 153–5 Leadenhall Street, E.C.

S.W.—Wandsworth Workhouse Infirmary. J. S. Gibson, 5 Old Bond Street, W. Builders, Johnson & Co., Belle Vue Road, Wandsworth Common.

Motor garage (250,000 to 400,000 cubic feet) in Lea Grove Road, Fulham. Architect, A. F. Nigers, 4 Fredericks Place, Old Jewry, E.C.

The wiring of Chelsea Town Hall is to be thoroughly overhauled and renewed by the Borough Council.

W.—180 New Bond Street is to be rebuilt by W. Cubitt & Co., 258 Gray's Inn Road, W.C., builders.

New refreshment saloon at the Lyric Opera House, Hammersmith. Architects, F. Matcham & Co., 9 Warwick Court, W.C.

W.C. Alterations and additions to St. Clement Danes Vestry Hall. Architect, John Murray, 11 Suffolk Street, Pall Mall East, S.W.

Block of shops and offices in Kingsway and Vernon Place. Surveyors, Grant Taylor and Atkinson, 39 Bloomsbury Square, W.C.

Business premises in Baldwin's Place, Holborn for Willmott & Sons, machine rulers, 55 Bartholomew Close, City.

PROVINCES.

ACTON.—A committee of the Council (W. Hodson, Clerk) are considering proposed additions to the hospital.

New Schools (£17,345). Architects, E. C. P. & H. Thomson, 182 High Street, Acton. Builder, A. Monk, Lower Edmonton.

AVELEY (Essex).—School to accommodate 120 children. Architect, Christopher M. Shiner, 10 John Street, Adelphi, W.C.

BOOTLE.—School. Architects, Grayson & Ould, 31 James' Street, Liverpool.

BRENTWOOD (Essex).—Grammar School. Architects, Chancellor & Son, Chelmsford.

BROMLEY.—Children's Home. Architect, Mr. Ladd, c/o Clerk to the Board of Guardians.

CHELMSFORD.—Offices (£5,000) for Essex Education Committee. J. H. Nicholas, secretary.

CROYDON.—Secondary School for Girls (£16,000 to £17,000). Builder, R. E. Nightingale, Albert Embankment, S.E.

DARTFORD.—Eleven houses, Nelson Road. Surveyors, Dann & Lucas, 23 Budge Row, E.C.

DERBY.—Extensions (£12,000) to asylum. G. Trevelyan Lee, Town Clerk.

DONCASTER (Near).—Church. Architect, C. Hodgson Fowler, The College, Durham.

DOVER.—Alterations to almshouses (£1,059). Architects, Worsfold & Hayward.

ENFIELD.—Secondary school and institute (£12,379). Builder, Treasure & Son, Holloway. Architect, H. G. Crothall, Guildhall, Westminster. Additions and alterations to the Grammar School (£6,155). Builders, Knight & Son, Tottenham. Architect, Mr. Crothall.

EPSOM.—Nurses' home and for additions and alterations to the workhouse. Architect, A. C. Williams, 14 Great James Street, Bedford Row, W.C.

GARNDIFFAITH.—Public hall and institute (£1,735). Architect, W. Beddoe Rees, 3 Dumfries Place, Cardiff. Builders, Bailey Bros., Pontnewynydd.

GOSPORT.—School (£7,500). Architect, E. J. Tench, Norwich.

GRAVESEND.—Schools (£9,353). Architect, J. J. Robson, 335 High Holborn, W.C. Builders, G. Gates & Sons, Frindsbury, Rochester.

HENDON.—Ten shops, Golder's Green Road. Builder, J. Gibb, Golder's Green Road, N.W. Motor garage, Woodstock Road. Builder, J. Gibb, jun., Golder's Green Road, N.W. Twenty-two houses, Dartmouth Road. Architect, H. Shaw, 6 Nicoll Road, Willesden, N.W. Two churches for Garden Suburb. Architect, E. L. Lutyens, 29 Bloomsbury Square, W.C. Nine shops, North End Road. Architect, A. W. Cleaver, 54-5 London Wall, E.C.

ILFORD.—Additions to laundry in Ley Street. Surveyors, B. Bailey & Co., 21 Ironmonger Lane, E.C. Church in Baxter Street. Architect, E. T. Dunn, 7 Roding Street, Ilford. Nine houses. Builder, F. B. Harrison, 166 Balfour Road, Ilford.

MANCHESTER.—Two schools. Henry Price, City Architect.

NEW MALDEN.—Three houses in Blagdon Road. Architect, Arthur Cole, "Mogok," Thurlestone Road, West Norwood.

NOTTINGHAM.—Addition to Baptist Church (£948). Architects, Geo. Baines & Son, 5 Clement's Inn, Strand, W.C. Additions (£7,200) to lace factory. Architect, A. Harrison Goodall, South Parade, Nottingham.

PLYMOUTH.—Workhouse infirmary (£32,000). Architects, Thornely & Rooke, 11 The Crescent, Plymouth.

RADCLIFFE (Lancs.).—Fire station. W. L. Rathenell, Surveyor, District Council.

SANDOWN (Isle of Wight).—Church institute. Rev. J. Agg-Large, St. John's Vicarage, Sandown.

SALTNEY.—School (300 places). Surveyor and Architect, S. Evans, County Offices, Mold, Flints. Builder, P. Williams, Overton-on-Dee, Ellesmere, Salop. Cost, £2,956.

SOUTH BANK (Yorkshire).—School (£9,400). J. C. Wrigley, Secretary Education Committee, Northallerton.

TWICKENHAM.—Leslie & Co., builders, Kensington Square, W., are to carry out additions to Cambridge Park House Laundry.

UXBRIDGE.—A new post office is to be put up by H.M. Office of Works, Storey's Gate, S.W.

WOLVERHAMPTON.—New works (to cover 10 acres) for Chubb & Co. Architect, G. Gordon Stanham, 26 and 27 Bush Lane, E.C

WORTH (Kent).—Residence (£754). Architects, Worsfold & Hayward, Market Square, Dover. Builders, G. H. Denne & Son, Deal.

WREXHAM.—Two houses (£955). Builder, W. H. Thomas, Oswestry. J. E. Yate, architect, 9 High Street, Wrexham.

TENDERS RECEIVED AND ACCEPTED

BELFAST.—For the supply of house service cut-outs and trolley wire, the tenders of Messrs. W. Lucy & Co., Ltd., and the British Insulated & Helsby Cable, Ltd., have been selected.

DUBLIN PORT AND DOCKS BOARD.—A recommendation has been made to accept the tender of the Vulcan Boiler and Insurance Co., for insuring electrical machinery of the Board at £173 10s. 9d. per annum, but this, together with other tenders, has been referred to the Engineer for report.

LONDON: *London County Council.*—The following tenders have been received for the road work and plate-laying for the reconstruction on the underground conduit system of the existing tramways (equal to 5·5 miles of single line) from Euston Road via Hampstead Road, High Street, Camden Town, Camden Road, and Parkhurst Road, to Holloway Road :—

	£	s.
R. C. Brebner & Co.	58,485	15
W. Manders (recommended) ...	59,761	6
Dick, Kerr & Co.	61,272	13
John Mowlem & Co.	61,471	0
J. G. White & Co	62,144	14
Robert W. Blackwell & Co. ...	63,114	5

The following tenders have been received for the roadwork and plate-laying, exclusive of the supply of rails and special trackwork for (1) the reconstruction for the overhead trolley system of electric traction of the existing tramways from Loughborough Junction to Norwood, and the construction for the same system of the new tramways from Hammersmith to Putney, and (2) the execution of paving works in connection with street widenings along the latter route. The amounts of the tenders, after correcting arithmetical errors, are as follows, the first column representing tramway works, and the second paving works :—

	£	s.	£	s.
G. Wimpey & Co.	45,713	4	2,595	16
W. Manders	45,976	10	2,404	16
Dick, Kerr & Co.	46,986	11	2,586	9
Fry Brothers	47,440	1	2,664	10
Reid Brothers	48,211	7	2,808	15
J. G. White & Co.	48,823	19	2,799	15
John Mowlem & Co. ...	49,593	10	2,096	11
Robert W. Blackwell & Co.	49,335	8	2,904	15
J. A. Ewart	57,504	8	3,330	6

Digitized by Google

The Highways Committee recommend that the tender of Messrs. G. Wimpey & Co. for the tramway works, and that of Mr. W. Manders for the paving works be accepted.

The following tenders have been received for the supply of two turntables and the covers required for use at the tramways central car repair *depôt* :—

	£
W. G. Bagnall, Ltd. (recommended) ...	250
Bolling & Lowe	360
Isca Foundry Co.	420
Cowans, Sheldon & Co	720

For the supply of laminated belting at the central car repair *depôt* the following tenders have been received :—

	£	s.
J. Hendry & Co. (recommended) ...	308	6
R. H. Haylock	332	1
G. Angus & Co.	335	11
S. E. Norris & Co.	339	10
Buck & Hickman	342	16

The following tenders have been received for the supply of 140 tons of rolled steel bars for magnetic brake shoes in connection with the Council's tramways :—

	£	s.
The Lilleshall Co. (accepted)	980	0
The Earl of Dudley's Round Oak Works	1,052	10
Frodingham Iron & Steel Co.	1,050	0
Henry Bessemer & Co.	1,260	0
Cammell, Laird & Co.	1,295	0

Woolwich.—The Borough Council has accepted the tender of Siemens Bros. Dynamo Works, Ltd., in substitution for that of the British Thomson-Houston Co., Ltd., for the supply of a motor alternator. At the last meeting of the Council, the Electricity Committee reported that in submitting for approval the final specification and conditions as agreed with the Borough Electrical Engineer, the British Thomson-Houston Co. declined to conform to the Council's Standing Order requiring them during the continuance of the contract to display upon the site of the works a copy of the rates of wages and hours of labour to be observed in carrying out work for the Council. The committee therefore approached three other firms whose guaranteed efficiencies of the alternator were appreciably near to that of the British Thomson-Houston. Siemens Bros.' Dynamo Works, Ltd., were prepared to agree to all the conditions of contract and to the Borough Electrical Engineer's specification without qualification, and if allowed to increase the amount of their tender from £775 5s. to £799 5s., were prepared to guarantee an increased efficiency as follows :—Full load, 83; three-quarter load, 81·5; half-load, 77·5; quarter load, 62 (guaranteed efficiency in original tender : full load 81, 75·6, 68·6, and 51·6 respectively). The offer of increased efficiency and the consequently amended tender has been accepted. The amount of the tender of the British Thomson-Houston Co. was £784 10s.

MIDDLESEX.—The County Council has received the following tenders for the construction of tramways :—Four miles one furlong 2·90 chains length in Finchley Road, Hendon, to the Great North Road, Finchley; 7 furlongs 5·5 chains length from the Edgware Road to Finchley Road, Hendon :—

Thomas Adams	£120,095
Dick, Kerr & Co., Ltd. (accepted)	£116,978
A. Fasey & Son	£127,978
Clift Ford	£116,978
Wimpey & Co.	£119,991
The County Engineer's estimate was	£121,346

Length of 1 mile 4 furlongs 9·6 chains from Green Lanes, Southgate, to Market Place, Enfield :—

Thomas Adams	£41,709
Dick, Kerr & Co., Ltd.	£40,643
A. Fasey & Son	£43,820
Clift Ford	£40,643
Holloway & Co.	£40,719
Law & Co.	£41,405
J. Mowlem & Co.	£40,342
C. Wall, Ltd.	£45,027
Wimpey & Co. (accepted)	£40,220
The County Engineer's estimate was	£41,349

WALSALL.—The tender of Messrs. Callender's Cable & Construction Co. for the cables in connection with the supply to the South Staffordshire (Lessee) Tramways Co., has been accepted at £800.

WALTHAMSTOW.—The Council has accepted the tender of A. Blackmore & Co. for twelve months' supply of 500 tons of anthracite washed peas from the Yniscedwyn Colliery at £1 1s. per ton. The offer of Babcock & Wilcox, Ltd., to provide and fix a coal elevator and distributing chutes at the generating station for £99 10s., has been accepted. For alterations and additions to the generating station the following tenders have been accepted : builders' work, W. Richardson, £530; steelwork, Norton Bros. & Co., £670.

COMPANIES' MEETINGS AND REPORTS

ANGLO-AMERICAN TELEGRAPH CO.—The report for the June half-year shows receipts, including the balance of £2,478 brought forward from the last account, amounting to £195,258. The traffic receipts show a decrease of £15,625, as compared with the half-year ended June 30th, 1907. The working expenses amounted to £73,296, being a decrease of £1,467, as compared with the corresponding period of 1907. The directors have set apart the sum of £10,000 to the renewal fund, leaving a balance of £111,962. Quarterly interim dividends of 15s. per cent. on the ordinary stock, and of £1 10s. per cent. on the preferred stock, were paid on May 1st, 1908, absorbing £52,500, and second quarterly interim dividends of 15s. per cent. on the ordinary stock, and £1 10s. per cent. on the preferred stock, amounting to £52,500, will be paid on August 1st, 1908. The balance of £6,962 will be carried forward to the next account. The meeting is to-morrow.

BRITISH THOMSON-HOUSTON CO.—The report for the year ended March 31st, 1908, states that during the year the company has developed a line of low-pressure turbines, several of which have been sold. All the Curtis turbine patent rights for the United Kingdom, with the exception of the marine rights, have been acquired. Under the terms of the trust deed securing the issue of the company's debentures the company had to pay to the trustees on February 28th last the sum of £3,339, to be applied by them in purchasing debentures in the market. Debentures of the par value of £1,160 were purchased prior to March 31st (the end of the year under review), and since the closing of the books the trustees have purchased an additional amount of £2,400, making the total par value of debentures retired £3,560. The trading profit for the year, after deducting general and technical expenses, discounts, debenture and other interest, amounts to £28,058. The whole of this profit, with the exception of £1,394 carried to the balance-sheet, has been applied, as shown in the profit and loss account, to various depreciations. The amount carried forward last year was £1,071, which, added to the above amount of £1,394, makes the total carried forward this year £2,466. On the balance-sheet of last year the balance of the excess cost incident to the establishment of the manufacturing business of the company amounted to £16,707 (£51,000 having been previously written off). Nothing was added to this account during the year, and the directors have decided to write off a further sum of £6,707, leaving a balance of £10,000, which will be written off from time to time until finally disposed of. The directors record with regret that during the year Mr. W. A. McArthur resigned as Chairman and director of the company. It is not proposed to fill the vacancy on the Board at present, and Mr. J. F. Nauheim has been elected to act as Chairman of the company. The meeting is to-day.

BRUSH ELECTRICAL ENGINEERING CO.—An extraordinary general meeting was held on Tuesday confirming resolutions passed on July 7th consolidating the fully-paid non-cumulative 7 per cent. shares of the company, and also the ordinary shares.

BUENOS AYRES NEW TRAMWAYS CO.—For the eighteen months ended March 31st, 1908, there is a credit balance, after providing for interest on the debenture stock, debenture and bonds, of £31,238. After deducting the debit balance of £29,806 from previous years there remains £1,432 to be carried forward.

CITY & SOUTH LONDON RAILWAY CO.—At the annual meeting on Tuesday the report and accounts given in our last issue were adopted. Mr. C. B. Stuart Wortley, K.C., M.P., the chairman, who presided, said that, notwithstanding all the additional charges which the extension to Euston had entailed, the working expenses still stood at the small proportion of only 46·28 per cent. of the receipts. With regard to the fire which had occurred at Moorgate Street Station on July 16th, he was not able to suggest any cause, owing to the matter now being the subject of a Board of Trade inquiry, but the company's officers were busily at work removing every discoverable thing that could possibly lead to a recurrence of such a fire, and every possible addition was being made to the existing provisions and regulations for securing the safety of the passengers. In answer to questions, the chairman said he could not promise that steel sleepers would be substituted for the present wooden ones all over the lines at once.

CROMPTON & CO.—At the annual general meeting on Monday the report and accounts given in our last issue were adopted. Mr. John Trotter, who presided, referring to the present position of the electrical industry, said that during the past three years reductions in the contract prices of electrical machinery had taken place varying from 16 per cent. to 25 per cent., owing to excessive competition. Fortunately, however, the company had made such an advance that they were able to refuse orders which did not leave a proper margin of profit. Sooner or later it would be necessary to increase the permanent capital of the company in order to cope with the growing expansion of the business.

Digitized by Google

CRYSELCO.—The balance sheet and accounts for the year ending May 31st, 1908, show that the business of the company continues to steadily improve, the profit for the year, including balance brought forward, being £6,081 1s. 9d. The number of lamps sold shows a substantial increase, and notwithstanding the very keen competition existing throughout the year, which has necessitated a still further reduction of price, it is satisfactory to note that a larger profit has been made. During the past twelve months the directors have spared no efforts to secure the company's position in regard to the development of the metal filament, and they have reason to believe that they will be successful during the present year in placing upon the market a metal filament lamp which should satisfactorily replace the demand for carbon filament lamps which is undoubtedly ensuing. Success will necessitate an increased working capital, which the directors hope may be met out of the revenue of the company, but it is possible that it may be necessary to raise additional capital. The directors recommend the payment of the usual dividend at the rate of 10 per cent. for the year.

DIRECT UNITED STATES CABLE CO.—The accounts of the half-year to June 30th, show a revenue of £51,367, against £57,056 for the corresponding period of last year. Working and other expenses amounted to £24,932, leaving a net profit, including £6,396 brought forward from the previous half-year, and £2,299 adjustment of income tax of £35,131. Three quarterly dividends of 4s. per share, and a final dividend of 4s. per share is now proposed, with a bonus of 1s. per share, making 4¼ per cent. for the year. After transferring £5,000 to the reserve fund, there is a balance of £2,812 to be carried forward.

DUBLIN UNITED TRAMWAYS CO. (1896).—The directors' report for the half-year ended June 30th, 1908, states that the amount available for division is £41,594, out of which it is recommended that dividends be paid for the half-year at the rate of 6 per cent. per annum on the preference shares, and at the rate of 6 per cent. per annum, free of income tax, on the ordinary shares. The dividends recommended will absorb £35,100, leaving £6,494 to be carried to next account, in addition to £4,749 unexpended out of the sum set aside last half-year for reconstruction and maintenance. At the meeting on Tuesday the report and accounts were adopted.

ELEKTRISCHE STRASSENBAHN VALPARAISO AKT.-GES, BERLIN.—The returns for the year ended December 31st, 1907, show that the number of car-kilometers has increased from 2,676,060 in the previous year to 4,061,960. The receipts have increased from $865,891 to $1,189,541, and the expenses from $638,189 to $922,260. The increased expenses were due to the damage caused by the earthquake of August last. The small balance remaining after deducting business expenses in Berlin and interest on debentures, has been placed to renewals account.

GENERAL ELECTRIC CO.—Mr. G. Byng presided at the annual general meeting on Friday, when the report and accounts given in our last issue were adopted. The Chairman said that the cause of the diminished profit was the necessity for writing down their stock owing to the sudden fall in the price of raw materials. Discussing the unsatisfactory position of the electrical industry, the Chairman said that some suggestion had recently been made that a league should be started as a combination of manufacturers in order to combat foreign competition. Personally, however, he did not think any permanent improvement would be made until our fiscal policy was altered.

METROPOLITAN RAILWAY CO.—The report for the half-year ended June 30th shows total receipts of £356,787, and expenses £199,780, leaving a profit of £157,007. Compared with the corresponding half-year of 1907 the receipts show an increase of £11,267, and the expenses an increase of £6,419. The net revenue account, after providing for the interest upon the debenture stocks and other fixed charges, and the dividend upon the preference stocks, shows a balance of £18,002 available for dividend upon the ordinary stock. The directors accordingly recommend a dividend upon the ordinary stock for the past half-year at the rate of 10s. per cent. per annum, and to carry forward the balance of £3,672 to the next half-year's accounts. The Surplus Lands Committee announce that the dividend on the surplus lands stock for the past half-year will be at the rate of £2 15s. per cent. per annum. During the half-year the train services have been considerably increased, and a greater mileage has consequently been run. The full benefit has not yet been felt in the receipts, but it is expected that as the greater facilities offered by the company become better known among the travelling public the traffic will respond. It is now more than twelve months since the last of the tube lines was opened, and the immediate effect of that competition is therefore known. The opening of the several tubes has caused a serious diversion of traffic from the Metropolitan line, but it has at the same time given rise to a large increase in the amount of local travel generally which will be a continuing benefit to this company. On some sections of the line the traffic during the half-year has shown a healthy expansion, and on others, where there has been a falling-off through competition, steps are being taken to prevent further loss and to regain the business. Owing to the delay in the completion and opening of the Franco-British Exhibition, the traffic from that source was not so great during the past half-year as was contemplated. It has, however, increased since the beginning of July, and it is fully expected that it will develope largely as the holiday and excursion season advances. Throughout the half-year the electrical plant and machinery have given every satisfaction in working, and the current continues to be produced at a figure which compares very favourably with other installations.

NATIONAL TELEPHONE CO.—At the half-yearly ordinary meeting on Thursday, Mr. George Franklin, Chairman, presiding, the report and accounts given in our issue for July 16th were adopted. The Chairman said the accounts were regarded by the Board as eminently satisfactory. The income for the half-year was £1,452,825, as compared with £1,315,038 in the corresponding period. The net income, after deducting Post Office Royalties, was £1,313,279, as against £1,189,739. There are now 463,869 stations, an increase of 16,761. The working expenses amounted to £832,638, an increase of £82,878, partly due to the normal growth of the business and partly to exceptional items. Maintenance and renewal of lines and instruments have increased by £27,629, indicating the resolve of the Board to keep the plant in a state of efficiency, a policy which should commend itself to the shareholders, since the purchase price to be paid for the business in 1911, on its transfer to the Post Office, would be based on plant values. Administration and management charges had increased by £38,178. The net result for the half-year was £480,641, against £439,979, being an increase of £40,661, and, as £596 more was brought forward, there was an additional sum of £41,257 to dispose of. Against this £7,518 represented increased debenture and other interest, £26,433 extra dividend, and £10,000 more to reserve fund. The reserve fund stood at £2,664,960, and its main purpose was to cover any possible shrinkage in the capital on the transfer of the undertaking in 1911. Some shareholders seemed to think that the reserve fund constituted excess provision. It might be so. If too great, the fund would remain the property of the shareholders, but if it were inadequate the shareholders of 1911 might have just cause of complaint against the directors. In the last week or ten days some eminent financial authorities had been attempting to forecast the price at which the deferred stock would be paid off in 1911. The Board had no responsibility for those forecasts, and saw no safe ground for such prediction. It might, and probably would, happen that arbitration would be resorted to in order to ascertain the purchase price payable, and it would be manifestly unwise for the directors to speculate on the subject or to do anything to create false hopes on the one hand or undue depression on the other. The rentals carried forward had grown from £1,210,117 to £1,314,591, an increase of £104,474 in the half-year. The capital expenditure had increased to £14,042,959, representing the amount expended on their 463,869 stations ,and giving an average cost of £30 5s. 6d. per station. Adding the amount expended upon land and biuldings, £685,309, a total of £14,728,269 was reached. Of this the share and debenture holders had provided £11,221,593, leaving an excess of capital expenditure of £3,506,676. The total of the assets in the balance-sheet was £5,157,456, which had been provided by rentals in advance, £1,187,629, creditors' balances, £935,438, and the reserve fund, £2,664,960, leaving a balance of £369,426, which was appropriated for the dividends, including 6 per cent. per annum on the deferred stock, for the addition of £140,000 to the reserve fund, and for the balance of £10,676 carried forward. Dealing with the adoption of the measured rate system of charging, the Chairman pointed out that there were now upon that system something like 100,000 stations, and it was gratifying that, after careful investigation of their agreements and of the proposed method of operation, a number of the more important municipalities, notably Liverpool and Belfast, had approved of the principle contended for. The company had adopted it only in regard to new subscribers, the old flat-rate subscribers being undisturbed. The adoption of this principle would, at all events, secure to the shareholders a fair and equitable return upon the capital which had now to be spent. The number of staff had increased during the year from 17,421 to 17,946, and the number of the shareholders showed a gratifying increase from 12,217 to 13,031. The number of exchanges was 1,513, and the number of stations, exchange and private, 463,869. The present rate of effective calls was 656,755,000 per annum, or of messages, including call and reply, 1,313,511,000. The accrued revenue per telephone station worked out at £6 3s. 4d., and the average cost per message to a subscriber was 0·48d., the average per week being 2s. 4d., or 4d. per day, including Sundays. So far as the London system was concerned, in December last the Post Office had 46,355 stations and the company 93,020; in June the corresponding numbers were 49,690 and 99,068, so that there had been an increase of 3,335 on the Post Office system against 6,048 upon that of the company.

SIEMENS BROS. DYNAMO WORKS.—The accounts for 1907 show a profit of £1,416.

TORQUAY TRAMWAYS CONSTRUCTION CO.—The accounts from the incorporation of the company (August 24th, 1905) for December 31st, 1907, show a profit of £2,271, which the directors recommend shall be carried forward.

Digitized by Google

UNITED RIVER PLATE TELEPHONE CO.—The report for the year ended March 31st last states that the gross receipts in the River Plate were £250,750, as against £216,204 for last year. Deducting expenses in Argentina and London, debenture interest, dividend on preference shares, and interim dividend on ordinary shares, and adding interest on investments, transfer fees, &c., there remains a profit of £77,739, to which is added £4,070 brought forward, making an available balance of £81,809. After applying £25,000 to the reduction of special replacement account, and meeting the cost of paying off the old debenture stock and the issue of the new, the directors recommend that a final dividend of 5 per cent. be paid upon the ordinary share capital, making, with the interim dividend paid December 31st last, a return of 8 per cent. for the year, free of income tax, and that £4,904 be carried forward. At the meeting on Tuesday the report and accounts were adopted.

WESTINGHOUSE AKT. GES., BERLIN.—The report for the year 1907 shows a loss of 83,945 Mk. The total loss up to date amounts to 185,624 Mk.

MISCELLANEOUS CITY NOTES

BRISTOL TRAMWAYS & CARRIAGE CO.—An interim dividend, at the rate of 6 per cent. per annum for the half-year ended June 30th, has been declared.

BRITISH COLUMBIA ELECTRIC RAILWAY CO.—A dividend at the rate of 5 per cent. per annum for the three months ended June 30th, together with an additional dividend at the rate of 1 per cent. per annum, on the deferred ordinary stock, is announced.

BROMPTON & KENSINGTON ELECTRICITY SUPPLY CO.—An interim dividend for the half year ended June 30th at the rate of 9 per cent. per annum on the ordinary shares is recommended.

CENTRAL LONDON RAILWAY CO.—Dividends of 3 per cent. on the undivided ordinary stock, 4 per cent. on the preferred ordinary stock, and 2 per cent. on the deferred ordinary stock have been declared. The carry forward is £29,125.

CHELSEA ELECTRICITY SUPPLY CO.—An interim dividend of 4 per cent. per annum (2s. per share) has been recommended on the ordinary shares for the half year ended June 30th.

CITY OF BUENOS AYRES TRAMWAYS CO. (1904).—A dividend of 1s. 3d. per share, less tax, has been declared for the three months ended June 30th.

ELEKTRISCHE LIEFERUNGS AKTIEN-GESELLSCHAFT OF BERLIN.—An extraordinary general meeting has been convened for the purpose of passing resolutions for increasing the capital of the company from 5,000,000m. to 15,000,000m.

IMPERIAL TRAMWAYS CO.—An interim dividend, at the rate of 8 per cent. per annum for the half-year ended June 30th, has been declared.

METROPOLITAN RAILWAY CO.—A dividend of 10s. per cent. per annum is recommended on the ordinary stock for the past half year, carrying forward £3,600. The dividend on the surplus lands stock will be at the rate of 2¾ per cent. per annum, carrying forward £1,800.

NORTH METROPOLITAN TRAMWAYS CO.—An extraordinary general meeting will be held on August 12th to consider a resolution that the capital be reduced from £499,153 10s. divided into 110,923 shares of £4 10s. each, to £488,061 4s. divided into 110,923 shares of £4 8s. each, by returning to the holders of the 110,923 issued shares capital to the extent of 2s. per share.

UNDERGROUND ELECTRIC RAILWAYS CO. OF LONDON.—An offer is being made to the holders of shares and profit-sharing secured notes, of £1,000,000 of 5 per cent. prior lien bonds to bearer maturing on November 1st, 1920. Interest is payable, free of income tax, half-yearly, on May 1st and November 1st. The bonds are offered at 93, and will be secured by a first specific charge on stocks and shares of the affiliated railway companies having a face value of £14,579,990.

VICKERS SONS & MAXIM.—An interim dividend of 1s. per share free of tax for the June half year is announced upon the ordinary shares.

APPOINTMENTS AND PERSONAL NOTES

Mr. Harry W. Turner, who, as Consulting Engineer, has, for the last two years, been occupied in advising firms in matters relating to insulation and winding, will, from August 1st, be associated exclusively with the Sterling Varnish Co., at Brougham Street, Blackfriars Road, Manchester.

The Imperial College of Science and Technology.—It is announced that the Royal Commissioners of the Exhibition of 1851 appropriated the whole of the remaining site of their estate at South Kensington for the purposes of the Imperial College of Science and Technology. The new mining and metallurgical buildings are to be proceeded with at once. Several additional appointments have been made, among which the Hon. R. J. Strutt, F.R.S., has been elected to an additional professorship of physics.

COMPANY MORTGAGES, &c.

ALSOP FLOUR PROCESS (1906).—Particulars have been filed of an issue on June 3rd of £196 9s. 6d. 5 per cent. second debentures, part of series created March 20th, 1908, securing £1,500, charged on the company's undertakings and property present and future, including new capital (subject to a prior debenture, of which £1,500 is still outstanding). The total amount previously issued of the same series is £901 8s. 9d. There are no trustees.

AMAZON TELEGRAPH CO.—A statement has been filed pursuant to Section 12 of the Companies Act, 1907, of the total amounts outstanding on July 1st, in respect of mortgage and charges created prior to that date, and not required to be registered under Section 14 of the Companies Act of 1900. The particulars are 5 per cent. debenture, dated August 5th, 1897, securing £136,700.

BRITISH WESTINGHOUSE ENGINEERS' CLUB.—A debenture has been registered, dated June 17th, 1908, securing £675 charged on the company's undertakings and property, present and future, including uncalled and unpaid capital. The holders are the British Westinghouse Electric & Manufacturing Co.

BRITANNIA ELECTRIC LAMP WORKS.—The appointment of Mr. J. J. B. Cress, of 65 Lindsey Road, Hornsey, as receiver and manager, has been filed, pursuant to Section 11 (2) of the Companies Act, 1907.

BUENOS AYRES ELECTRIC TRAMWAYS COMPANY (1901), LTD.—An acknowledgment of indebtedness under seal, dated June 29th, 1908, to secure a further £7,000 Second or "B" Debenture stock (ranking *pari passu* with and supplemental to £71,600, forming part of a total authorised sum of £100,000 similar stock, secured by a trust deed dated March 30th, 1906, and two acknowledgments of indebtedness dated March 7th, 1907, and May 27th, 1908), has been registered. Property charged:—certain tramway concessions, freehold land, rights, and the company's undertaking and property, present and future, including uncalled capital. Trustees: W. Greenwell, 2 Finch Lane, E.C., and F. C. Tiarks, 145 Leadenhall Street, E.C.

D. P. BATTERY COMPANY, LTD.—A statement of the total amount outstanding on July 1st in respect of mortgages and charges created prior to that date and not required to be registered under Section 14 of the Companies Act, 1900, has been filed pursuant to Section 12 of the Companies Act, 1907. Particulars are debentures, bearing various dates in 1899, securing in all £4,500.

EASTERN EXTENSION, AUSTRALASIA & CHINA TELEGRAPH CO.—A statement has been filed pursuant to Section 12 of the Companies Act, 1907, of the total amount outstanding on July 1st, in respect of mortgage and charges created prior to that date, and not required to be registered under Section 14 of the Companies Act, 1900. This relates to a mortgage dated November 19th, 1890, securing £320,000 debenture stock.

NATIONAL TELEPHONE CO.—A statement has been filed pursuant to Section 12 of the Companies Act, 1907, of the total amounts outstanding on July 1st, in respect of mortgage and charges created prior to that date, and not required to be registered under Section 14 of the Companies Act, 1900. The particulars are a trust deed constituting a first charge on the company's undertakings and property dated November 8th, 1894, securing £1,100,000; 3½ per cent. debenture stock, and two supplemental deeds dated March 9th, 1895, and December 6th, 1898, securing £363,448 and £536,552 respectively.

SANDYCROFT FOUNDRY CO.—Particulars have been filed of an issue on June 25th of £3,100 6 per cent. debentures, part of series created April 15th, 1908, securing £20,000 charged on the company's undertakings and property present and future, including uncalled capital. There are no trustees, and there has been no previous issue of the same series.

SAXON ENGINEERING CO.—Particulars have been filed of an issue of £2,000 6 per cent. third debentures created June 4th, 1908, charged on the company's property present and future, including uncalled capital. There are no trustees.

SYNDICATE OF ELECTRICAL ENGINEERS.—A statement has been filed pursuant to Section 12 of the Companies' Act of the total amount outstanding on July 1st, in respect of mortgages and charges created prior to that date, and not required to be registered under Section 14 of the Companies' Act, 1900. The particulars are a mortgage on leasehold land and premises in Southampton Row, dated September 28th, 1905, securing £13,800.

TRAMWAYS & LIGHT RAILWAYS ESTATE CO.—A statement has been filed pursuant to Section 12 of the Companies' Act of the total amount outstanding on July 1st, in respect of mortgages created prior to that date, and not required to be registered under Section 14 of the Companies' Act, 1900. The particulars are a charge dated September 23rd, 1902, securing £700 upon property at Moxham's Yard, Oystermouth Road, Swansea.

Mining Institute of Scotland.—A general meeting will be held at the Oddfellows' Hall, Kilmarnock, on Saturday, August 8th, when a Paper on "Experiments with Two Electrically-driven Pumps" will be read by Mr. T. Lindsay Galloway.

Digitized by Google

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £60 10s. to £61 per ton (last week, £59 10s. to £60 per ton).

ANNUAL HOLIDAYS.—The works and offices of Messrs. Parmiter, Hope & Sugden, Manchester, will be closed from 12 noon on Saturday, August 8th, until 9 a.m. on Monday, August 17th, 1908, for the annual holiday. No goods will be received between these dates, but a small staff will be in attendance to deal with urgent matters.

The Arc Works, Chelmsford, will be closed from noon, Saturday, August 1st, until Monday, August 10th. No goods should be dispatched to arrive during that period. Messrs. Crompton & Co.'s head office, Salisbury House, London Wall, will, however, remain open for business as usual.

CHANGE OF ADDRESS.—Messrs. Davidson & Co., Ltd., have removed to larger premises at Egypt House, New Broad Street, London, E.C Telephone No., London Wall 2246.

DISSOLUTION OF PARTNERSHIP.—F. W. Cross and A. A. P. D. Stone, trading as electrical engineers, &c., at Pleck Road, Walsall, have dissolved partnership.

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—The Cornwall Electric Power Syndicate, Ltd., is to be wound up voluntarily. Particulars of claims to the liquidator, J. A. Stoneham, 89 and 90 Cheapside, London, by August 31st.

The Allan Electrical Syndicate, Ltd., is to be wound up voluntarily. Mr. H. Garton Ash, 52 Coleman Street, London, E.C., is liquidator.

A meeting of the Llanelly Tramways Co., Ltd., will be held at 52 Stepney Street, Llanelly, Carmarthenshire, on Thursday, August 27th, at 3 p.m., for the purpose of hearing the liquidator's account of the winding up.

A meeting of the Dolter Electric Traction Co., Ltd., will be held on Wednesday, August 5th, at 2.30 p.m. at the office of the liquidator, Mr. W. S. Ogle, 90 Cannon Street, London, E.C., to determine whether application shall be made to the Court for the appointment of any person as liquidator in the place of, or jointly with the liquidator appointed by the company, or for a Committee of Inspection. The creditors of Reeds Electrical Co., Ltd., are requested to send in particulars of their claims by September 7th to the liquidator, Mr. D. S. Fripp, 90 Cannon Street, London, E.C.

The trustee in the bankruptcy of E. J. Muddle, electrical fitter, 69 Cromwell Road, Hove, has been released.

The adjourned public examination of Ernest Albert Gresham, late electrical engineer, 6 Harehills Avenue, Leeds, late Westborough, Scarborough, was held last week at the County Court House, Albion Place, Leeds, before Mr. Regr. Cautherley, the liabilities being stated at £203 with assets £19. The debtor started business in Scarborough in 1889. A further adjournment was ordered.

The public examination of Francis Benjamin Egginton, electrical engineer and contractor, 11 Tempest Street, Wolverhampton, was held last week at the County Court, Wolverhampton, the deficiency being stated at £82. Debtor said the trade had declined considerably, and competition had been very keen. An adjournment was ordered.

The adjourned public examination of Alfred William Bennett (lately trading as Bennett & Co.), electrical engineer, 43 Elford Grove, late 32 Park Cross Street, Leeds, was held last week at the County Court House, Albion Place, Leeds, before Mr. Regr. Cautherley, the deficiency of £1,124 being ascribed by the debtor to bad trade and competition. The case was adjourned.

NEW COMPANIES

MALLINSON BROTHERS (1908).—This company was registered on July 11th, with a capital of £500 in £1 shares, to carry on the business of tool-makers, iron-founders, mechanical and electrical engineers and manufacturers of dynamos, motors, carriages, vehicles, and engines, and to acquire the business carried on at Mytholm Foundry, Hipperholme, Yorks, as Mallinson Brothers, and to adopt an agreement with J. Mallinson and W. Mallinson. Private company, with only two subscribers, viz.: J. Mallinson and W. Mallinson, machine tool-makers, of 15 Waverley Terrace, Hipperholme, taking one share each. The number of directors is not to be less than two nor more than five. The first are J. Mallinson and W. Mallinson, and each may retain office while holding £50 shares.

PREMIER ELECTRIC CONTROL.—This company was registered on July 9th, with a capital of £7,000 in £1 shares (1,500 preference), to acquire the business carried on at 11 Red Lion Street, Clerkenwell, E.C., as "E. P. Allam & Co.," to adopt an agreement with L. I. Robinson and A. E. Ralph, and to carry on the business of manufacturers of electrical controlling gear and motor starters and regulators, electrical engineers and contractors, electricians, &c. Private company, with only two subscribers, viz., A. E. Ralph, 11 Red Lion Street, E.C., engineer, and H. E. Aldridge, 16 Warwick Street, Regent Street, W., solicitor, each taking one share. The number of directors is not to be less than two nor more than seven; the first are L. I. Robinson and A. E. Ralph. Qualification, £500. Remuneration of original directors, £15 per annum, divided, in respect of every completed sum of £1,000, by which the share capital of the company paid up, or credited as paid up, may be increased beyond £6,000; of other directors, £25 each per annum. The directors (including original directors) are further to receive 15 per cent. of the surplus profits remaining after 10 per cent. is paid on the ordinary shares. Registered office: 11 Red Lion Street, Clerkenwell, E.C.

RUGBY LAMP CO.—This company was registered on July 4th with a capital of £10,000 in £1 shares, to adopt an agreement with B. H. C. Fox, of Maplewell, near Loughborough, and T. Hunter of Rugby, for the acquisition of a piece of freehold land fronting Lower Hillmorton Road, Rugby, and to carry on the business of manufacturers of and dealers in arc, incandescent, and other electric lamps, lighting appliances of all kinds, &c. Private company with three subscribers, viz.:—T. Hunter, J. Findlay, T. H. V. Hunter. The number of directors is not to be less than two nor more than five; the first are T. Hunter and J. Findlay. Qualification, £250. Remuneration as fixed by the company. The said T. Hunter and J. Findlay may not reduce their respective holdings below 2,000 and 500 ordinary shares respectively during the first five years, except in the event of the death or removal from office of either of them, when the shares of the deceased or retired director shall be offered to the survivor at a price to be fixed by the auditors. Registered by Jordan & Sons, 116-117, Chancery Lane, W.C.

SYNDICATE LAMP CO.—This company was registered on June 29th, with a capital of £2,000 in £1 shares, to adopt an agreement with the Metallfadenlampenwerk, Perlin, G. m. b. H., and to carry on the business of manufacturers of and dealers in filament or other lamps, electricians, engineers, suppliers of electricity, &c. The subscribers are R. Hilditch, J. Makin, N. R. Stirling, T. D. Jones, G. R. Makin, H. B. Walton, and E. W. Barnaby. No initial public issue. The number of directors is not to be less than two nor more than five; the subscribers are to appoint the first. Qualification, £50. Registered office: 56 Spring Gardens, Manchester.

Marathon Race.—It is of interest to note, in connection with this historic event, that the signal for the start was conveyed by H.R.H. the Princess of Wales by means of an electrical device. This consisted of an indicating apparatus fixed in a suitable position behind the competitors, which was operated by a special push on the table in front of the Princess. Mr. J. S. Huddleston, of Messrs. Siemens Brothers & Co., Ltd., who was one of the stewards, fitted up the apparatus, which was made at the Woolwich Works of the above company.

Associated Municipal Electrical Engineers (Greater London).—The annual general meeting of this association was held at the Frascati Restaurant on Friday, the 24th inst., and the following officers were elected for the ensuing year:—President, C. Newton Russell (Shoreditch); Vice-Presidents, G. G. Bell (Hammersmith), W. C. P. Tapper (Stepney), W. C. Ullmann (East Ham); Treasurer, G. G. Bell (Hammersmith); Auditors, A. J. Fuller (Fulham), P. E. Rycroft (Heston); Hon. Secretary, A. H. Shaw (Ilford); Council, S. W. Paynes (St. Pancras), J. R. J. Bowden (Hackney), A. C. Cramb (Croydon), C. S. Davidson (Mortlake), A. Gay (Islington), A. C. Gilling (Epsom), C. F. McInnes (Gravesend), L. L. Robinson (Hackney), E. Sayer (Hampstead), A. H. Seabrook (West Ham), N. Staniland (Hornsey), J. E. Tapper (Beckenham).

Telegraph Traffic. Communication between Cayenne and Salinas has been restored, and this renders possible through communication *via* Hayti to Brazil. The Venezuela cables are still inoperative, while the Port Arthur-Chifu cables, closed during the Japan-Russian War, have not yet again been opened. The Las Palmas-Arecife, Pera-Dardanelles, Sierra Leone-Accra, Cadiz-Tangier, and Djedda-Suakim cables are not yet in working order, although the first three have been interrupted since May last. The Kwandang-Merado and Cotoron-Grand Bassam cables also still remain broken. The cable steamer *Mexican* put into Halifax, Nova Scotia, after repairing a Western Union Co.'s cable damaged 150 miles off that port, and eventually sailed for New York. A new cable is being laid connecting Sevastopol and Varna in Bulgaria, while the Bulgarian Government are also in negotiation for the installation of a Marconi wireless station at Varna. Telegraph construction is going ahead in Africa, judging by the large number of offices which have been opened recently. Telegrams may now be accepted for Kadugli in Egypt, Nyanga in Cameroon, Kpandu in Togoland, and Baro, Katcha, Kuta, Offa in Northern Nigeria, and Ede, Ilegbo, Ikerun, Iwo, Lalupon, Okuku, Olodo, Origo, Ozo Road, Shaki, Itu, and Uwet in Southern Nigeria, while two new stations have been opened at Tamale and Wa in the Gold Coast.

SUMMARY

An article by Messrs. W. F. Mitchell and J. Fernie considers a number of points in connection with the possibility of keeping down the cost of small house services—an important necessity in view of the reduced revenue per consumer, consequent upon the advent of the metal-filament lamp. (Page 203.)

Reviews of the following appear in this issue:—"Power Gas Producers," by P. W. Robson; "The Post Office Electrical Engineers' Journal," Vol. I., Part II. (Page 205.)

The tramway system of the Manchester Corporation has been extended to the amount of seven miles during the past year, and now comprises 177 miles of single track. The accounts show that the working costs during the year amounted to 7·07d. per car mile, excluding capital charges, or 10·87d., including capital charges. The total receipts amounted to 10·87d. per car mile, against 11·12d. for the preceding year. The gross balance for the year's working was £271,153, and after meeting all charges, and setting aside £87,790 for reserve, renewals and depreciation fund, a contribution to the rates of £55,000 was made. (Page 206.)

The London and District Electricity Supply Bill was read a second time in the House of Commons on Thursday. Mr. Chaplin (Wimbledon) moved the rejection of the Bill, and was supported by representatives of Fulham, Bethnal Green, Dartford, Kingston-on-Thames, Woolwich, Westminster, and Kent (Sevenoaks). Mr. McKinnon Wood said that he felt bound to vote for the second reading for the reason that, although he preferred a complete municipal scheme, there was no possibility of it being put forward, and he was not justified in voting in such a manner as to bring about further delay. He did not approve of the terms of purchase, but these could be left to the Committee. Mr. Winston Churchill, the President of the Board of Trade, in moving that the London County Council be mentioned in the Bill as the purchasing authority, said that the Board of Trade intended to apply a common policy to all three Electric Supply Bills now before Parliament, namely, that the London County Council should be the purchasing authority. In supporting the present Bill the Board of Trade did not approach the matter from the party point of view. This was the fifth successive year in which attempts had been made to pass such a scheme, and the uncertainty had hung like a pall all the time over the electrical industry. Having regard to the conditions in London, he held the view that the House of Commons would take a very grave responsibility if it disregarded the proposals now put forward without giving them de-

Digitized by Google

tailed attention at the hands of a Committee of the House. (Page 207.)

In a recent article in an American periodical, Mr. J. S. Peck compares the British, American, and German standards for electrical apparatus. In general, he finds that the American standards are stricter than the German, while the British standards are about halfway between the two. (Page 207.)

A short article gives some particulars of the operations of the Rio de Janeiro Tramway, Light, & Power Co., including one of the largest water-power installations yet constructed. (Page 208.)

The electrical equipment of the Ferndale Collieries is a fine example of the application of electrical distribution of power to mines. Current is supplied to a group of eight pits from a steam-driven power station containing slow-speed alternators. The transmission to the pits nearest the power station is at 2,200 volts, and to the more distant pits at 6,600 volts, by overhead lines. Electricity is used in the mines for ventilation, haulage, pumping, and lighting, as well as for driving workshops on the surface. A large electric winder on the Ilgner system is being erected. (Page 209.)

A method of manufacturing reinforced concrete poles for tramway work or for distribution lines has been introduced recently into this country. The process, which is the invention of Mr. Hans Siegwart, of Lucerne, consists in pressing concrete on to a sheet metal core, which is surrounded with a skeleton reinforcement consisting of longitudinal rods and spirally-wound wire. This skeleton becomes completely embedded in concrete, and when this is set the internal sheet metal core is withdrawn. This leaves a hollow pole of reinforced concrete. Poles manufactured by this process have already been used on distribution lines in Switzerland and elsewhere. (Page 217.)

The first portion of a series of definitions of terms used in electrical engineering which have been prepared by a sub-committee of the British Committee of the International Electrotechnical Commission has been issued. (Page 218.)

Some extensions are in progress to one of the elevated railways in Chicago. Details of the steel structure and track equipment are given in an article, and may be regarded as typical of American overhead railway construction. The third-rail system is adopted. (Page 221.)

A note is given under Electrometallurgy and Electrochemistry of the way in which sulphur can be entirely eliminated from the charge in the Heroult form of electric steel furnace. An installation of a group of 750-kw. Keller furnaces which have recently been set to work at Unieux is also described. (Page 223.)

Under Electrical Science, in the British and American Section, some recent work on the temperature coefficient of the resistance of silicon is described. In the Papers abstracted in the Continental Section, E. Branly deals with the wireless control of mechanisms and with thermoelectric detectors, and Cotton and Mouton investigate the electric double refraction in nitrobenzene. (Page 223.)

A new form of drawing-in tape for interior conduit work has been introduced. (Page 224.)

Among the Patent Specifications published by the Patent Office on Thursday last is that of C. H. Stearn and C. F. Topham for the "Stearn" multiple metal-filament lamp, which consists of a number of lamp units in series. A specification by C. H. Hyde describes a method of making conducting joints between the filaments and the leading-in wires of metal-filament lamps. The Allgemeine Elektricitäts Gesellschaft has one relating to the speed regulation of single-phase commutator motors, particularly to regulation at speeds above that of synchronism; and a specification by Siemens & Halske describes a simple process for removing the carbon from metal filaments by heating the filament in an atmosphere of acetic acid. An application for amendment to a patent relating to electric igniters for internal combustion engines has been made by De Dion Bouton, Ltd. A patent for a process for the evacuation of lamp bulbs, taken out by A. Maligani, and another for a diaphragm for electrolytic cells, by M. Kiliani and others, expire during the current week. (Page 225.)

Negotiations have been carried on between the London, Brighton & South Coast Railway Co. and the Brighton Corporation for a supply of electricity to the railway company's works there. The company will take a supply for five years, but it will be discontinued between 5.30 p.m. and 8 a.m. during December and January. The terms of payment are a fixed charge of £750 per annum, plus 0·56d. per unit. It is estimated that the consumption will be from 500,000 to 750,000 units per annum.—The Edinburgh Corporation has decided to transfer £9,794 of the surplus electric lighting profits for the past year to the relief of rates.—The tenth anniversary of the opening of the State telephone service in Guernsey was celebrated last week.—No further action will be taken by the Greenwich Borough Council with regard to Major Cardew's experiments for deodorising sewer gases by means of ozone generating apparatus.—A suggestion has been made to the Islington Borough Council by the London County Council that the period for repayment of loans, namely, 42 years, should be shortened in respect of loans already sanctioned, but the Borough Council do not approve of it.—For the second financial year of the Marylebone electric lighting undertaking there is a gross income of £161,492, compared with £158,459 for the previous year. After meeting capital charges there is a deficiency of £3,136, which the Committee attribute mainly to the low average price obtained, namely, 1·389d., against 1·45d. per unit for the previous year.—A resolution will be moved at the next meeting of the Stepney Borough Council opposing the continuance of experiments with the G.B. surface-contact system in the Mile End Road. (Pages 227 to 229.)

Local Government Board inquiries have been held at Dartford (£2,880) and Eccles (£16,278) for electricity extensions. An electric lighting plant is required at the Nurses' Home, Upper Edmonton. The Manchester Electricity Committee require a storage battery at the Stuart Street station, and low-pressure pipework, &c., at Dickinson Street station. A storage battery, motor-driven booster, and switchboard is required on the training ship *Exmouth* by the Metropolitan Asylums Board. The Watford Corporation requires a surface condenser and steam-driven pumps. Sixteen electric cranes are required at Auckland (N.Z.). For the information of wiring contractors we give particulars of a large number of buildings about to be erected in London and the provinces. (Pages 229–230.)

After providing for interest and rents, and for a dividend of 4 per cent. on the preference shares, the accounts of the Baker Street and Waterloo Railway Co. show a balance of £9,834; a dividend of ¾ per cent. per annum is declared upon the ordinary shares. The accounts of the Central London Railway Co. show a balance of £74,125, after providing for interest and debenture stock, &c. A dividend of 3 per cent. per annum is declared on the undivided ordinary stock, and 4 per cent. on the preferred ordinary stock. The report of the Charing Cross, Euston & Hampstead Railway Co. for the June half-year shows a balance of £832, after providing for interest and rents. At the half-yearly meeting of the East London Railway Co. last week Lord Claude Hamilton stated that the estimated

Digitized by Google

cost of converting the lines to electric traction was £59,600 under one scheme, and £79,600 under another. There is a balance of £419 upon the working of the Great Northern & City Railway for the June half-year. A dividend of ¾ per cent. has been declared upon the ordinary shares of the Great Northern, Piccadilly, & Brompton Railway Co. There is a balance carried forward of £4,886. The report of the Edmundson's Electricity Corporation for the year to March 31st, states that there is a net profit, after payment of debenture interest, of £2,610, to which is added £17,807 brought forward. The directors recommend that both these sums be carried forward. After providing for rent charges, interest on debentures, and other charges, there is a deficit of £8,957 upon the working of the Metropolitan District Railway for the June half-year. (Pages 231 to 233.)

In another column will be found the first portion of a series of definitions of terms used in electrical engineering, which have been prepared by a sub-committee of the British Committee of the International Electrotechnical Commission. The object of these definitions is not so much the provision of a glossary to explain the meaning of the various terms to students or laymen, as a laudable endeavour to facilitate uniformity in nomenclature by indicating such terms as are considered by the committee as suitable, and distinguishing them from those in common use, which for various reasons are not recommended. It may be questioned, however, whether the gain obtained by persuading the few engineers who will be induced to discontinue the use of the offending expressions is at all commensurate with the immense labour involved in the preparation of this electrical dictionary, containing, as it does, much of the obvious. We do not suggest that when completed the work will be without its uses; for example, it should be of great assistance to various compilers of engineering literature and to foreign firms tendering to British specifications, although the latter reason may not meet with unmixed approbation. We trust that our foreign friends will see the advisability of assisting our own manufacturing firms in a similar manner, both by compiling such dictionaries and by abating some of the high tariffs against imported electrical machinery. The attempt to standardise phraseology of any kind naturally involves many debatable points, and probably before the definitions are finally adopted some modifications will be made. We notice that the term "dynamo" is to be limited to continuous-current machines only, and "generator" is recommended as the general designation of apparatus for converting mechanical into electrical energy. We would suggest that the derivation and recognised use of the word dynamo renders it fitted for this general employment, and although the word generator will undoubtedly remain, it is unsuitable for international purposes, owing to the employment of "*generateur*" in French in the sense of boiler, while to increase the confusion "*generatrice*" is the equivalent of the English term generator. Taken as a whole, the definitions are excellently worded, although we do not like the expression "induced part of one motor" in the definition of cascade connection. Much difference of opinion has always existed regarding the relative merits of "continuous" and "direct" current. Although in some ways the term continuous is to be preferred, we think that it is useless to attempt to suppress the well-known abbreviation D.C., and substitute C.C., which is already often used to signify concentric cable; nor do we consider that the endeavour to prevent the field magnets of dynamos being spoken of as fields will meet with much success. We heartily agree with the limitation of the term electrocution—it it is to be used at all—to the form of capital punishment, which was the subject of such revolting experiments in America not long ago. We must, however, protest most strongly against the use of "diversity factor" in the sense usually understood by the term "load factor," that is, ratio of average to the maximum load, and would remind the committee that the meaning of the expression diversity factor as adopted by all engineers is: the ratio of the sum of the consumer's maximum demands to the maximum demand on the station. As the date of the meeting of the International Commission in London is drawing near, some more definite statement of the work to be done and the proposals to be put forward would be acceptable. We cannot think that the activities of the British Committee have so far been limited to the production of the first part of a glossary, the need for which has not been urgently felt in this country at any rate, and in the unofficial issue of an ingenious but fantastic proposal for an entire re-modelling of the system of physical symbols used by present-day writers.

The second reading debate upon the London and District Electricity Supply Bill in the House of Commons on Thursday was remarkable for a very broad-minded statement by the President of the Board of Trade upon the question of electric power supply in London, although the discussion showed strong signs of that purely party feeling which has prevented so many Bills in the past from being considered upon their merits. Mr. Winston Churchill's speech was a model of fairness compared with the remarks of some other speakers in the debate, who ignored the real facts and referred to the Bill as giving the company unrestricted powers in every conceivable direction. The Bill now goes to a Committee of the House of Commons with special powers to deal with the question of purchase; if any serious alterations are made in the Bill in this respect it would appear that they will come from the Committee itself, for the London County Council have intimated that they are satisfied with the Bill and have not lodged a petition against it, and none of the other opponents before Lord Cromer's Committee based their case upon this point. The application of one principle with regard to purchase to all three Bills will open up quite a new controversy before this Committee on a point which was not before Lord Cromer's Committee, for the reason that the two Bills of the electric lighting companies did not deal with purchase at all. Presumably considerable opposition may be expected from the Borough Councils to the proposal of the Government that all purchasing powers shall be delegated to the London County Council. It is even conceivable that the companies may oppose if the new position thus created has the effect of making the terms of purchase more favourable to the purchasing authority. But whatever may be the result to the interested parties, a very complicated situation will have been made much more simple if this principle is applied in a satisfactory manner. All the doubts which now exist under the

Digitized by Google

Electric Lighting Acts as to the actual terms of acquiring the existing companies should disappear, together with the involved question of compensation for "severance," which has been brought into existence by the facts that there are so many Borough Councils in the county of London with small areas, and that there are companies whose areas include portions of several of these local areas. In the light of the views expressed on behalf of the Government in the second reading debate upon the London and District Electricity Supply Bill, viz., that a bulk supply scheme for the metropolitan area is needed, it is reasonable to suppose that the proceedings before the House of Commons Committee will take a somewhat different aspect from those before former Committees. This is the first definite official pronouncement upon the subject, and it would seem to leave the Committee no alternative than to pass the Bill with the alteration indicated by the Government. Taken altogether there seems to be every prospect of the final settlement of a matter, the uncertainty surrounding which during the past five years has, it is admitted by the Government, "hung like a pall upon the electrical industry." After Mr. Churchill's speech we have a right to expect his energetic assistance to improve the status of the electrical engineering industry, not only in the metropolis but over the whole British Isles, for he has definitely asserted his view that "cheap electricity is scarcely less important than cheap and abundant food."

Occasions for the commemoration of anniversaries in connection with engineering and applied science are rarer than in the case of general national, international, or political history. A war between nations is usually decided by a particular battle, epoch-making alliances are made by treaties adopted on particular dates, and the same applies equally to the signing of the Magna Charta and the passage of Acts of Parliament of great social or political importance; but the subjugation of the great sources of power in Nature for the use and convenience of man is a gradual process, and it is often difficult to assign a definite date or even the name of a particular pioneer to some of the greatest discoveries and inventions that have been made in the realms of engineering. Submarine telegraphy is an instance in point. The laying of the first submarine cable in 1850—between England and France—was due to the enterprise and persistent energy of Jacob and John Brett. The first cable failed almost directly it had been laid, but a second cable, which was enabled to be laid in the following year by the assistance (both financial and otherwise) of Crampton, enabled public messages to be interchanged. A more definite date, somewhat later in the history of submarine telegraphy, is August 5th, 1858. Yesterday was the fiftieth anniversary of the completion of the first telegraph cable across the Atlantic Ocean, and although it was but two months before the insulation of this cable failed, it enabled the whole theory and practice of long-distance submarine telegraphy to be placed on a definite and permanent basis. The history of this cable was so recently related by Prof. Silvanus Thompson in his commemorative lecture upon the life and work of Lord Kelvin (Electrical Engineering, Vol. III., p. 692), that it need only be referred to briefly here. The Bretts were again concerned in the initiation of the scheme, and Cyrus Field, Charles Bright, and William Thomson (Lord Kelvin) are three names that stand out prominently in connection with it. Had it not been for these enthusiasts, the attempt would not have been repeated after two failures, and after the cable broke down within two months of its completion on account of Thomson's advice having been disregarded, it was to him that the success of the next cable was due. The cable completed fifty years ago yesterday was a good piece of engineering work, although it succumbed to the method of operation employed, and August 5th, 1858, may be put down as one of the most important dates in the history of the world, and one of those that identifies Great Britain with the supremacy in the great engineering industries.

Telegraph Traffic.—Very little alteration has taken place in the records of land-line and submarine cable interruptions and repairs which we published in our last issue. The only restoration of communication to be notified is that between Rome and Constantinople, which was again in working order on the 29th ult. Once again we have to record the failure of telegraphic communication between Trinidad and British Guiana, the cable having become interrupted on the 31st ult. As usual, every sailing and steamer opportunity will be availed of to send messages forward. Work on the wireless installation between Trinidad and British Guiana is being taken in hand. The Lodge-Muirhead system is already working between Trinidad and Tobago, and the same system will be employed in the new installation. The Turkish Government are about to lay a cable about 22·437 kilometres in length to connect the Imbros Islands with some place on the European coast. A land-line about 12·5 kilometres in length will connect Parayia, where the telegraph office is situated, with Ayia Toufolia, and the cable, which will land in the Dardanelles, will be connected by land-line with the cable between Kilid-ul-Bahr. The line between Rome and Pera was again down on the 1st inst. A new telegraph office has been opened at Kanus, in German South-East Africa, and at Mulondo, in Angola; while Hillstation and Wilberforce in Sierra Leone are now telegraphically connected. We are able to announce that the Russian administration opened the submarine telegraph cable between Sevastopol and Varna on the 2nd inst. for traffic.

The Brakpan Station of the Victoria Falls Co.—Some particulars of the steam plant which the Victoria Falls Co. is erecting at Brakpan, near Johannesburg, to supply electric power until they complete the scheme for bringing power from the Falls are given in our contemporary, *African Engineering*. The machinery now being installed will consist of two turbo-alternators, each of 3,000 kw. These are being erected on one side of the old power-house, but in an independent building. The generator house, which is built entirely of steel framework and brick, measures about 50 ft. by 120 ft., whilst the boiler-house is of the same length, but about 20 ft. wider. A third building has been put up on the opposite side of the old power-house to cover the transformers and switchgear. It is 100 ft. long by 60 ft. wide. The turbo-alternators will generate three-phase current at 10,000 volts, which will be transformed up to 40,000 volts for transmission. They are erected on high concrete foundations, so as to enable the condensers, &c., to be arranged beneath. The air and circulating pumps are driven by separate electric motors, and a 20-ton travelling crane runs along the whole length of the building. The boiler-house, which is covered with corrugated iron, contains eight Babcock & Wilcox water-tube boilers of 1,500 h.p. each, fitted with superheaters, and the economisers, coal-bins, &c. Forced draught is to be adopted, and the steam will be supplied to the turbines superheated about 100° C. A special feature about the boiler-house will be the coal-handling gear, which, in conjunction with the chain-grate stokers, will eliminate practically all manual labour. The transformer house is a three-storey brick and steel building, divided into four departments. At one end the transformers and lightning arresters will be installed, whilst the opposite end will be devoted to two accumulator batteries and a motor-generator for charging the batteries. The switches are all to be operated electrically from a separate room, and the switchboards are to be of marble throughout.

Sheffield-Warrington Electric Railway.—It is stated that a scheme is being inaugurated for the construction of an electric railway between Sheffield and Warrington, passing through Macclesfield, Chelford, Buxton, and Nutsford.

ON THE COST OF SMALL HOUSE SERVICES

By W. F. Mitchell and J. Fernie

THE arrival of metallic filament lamps and the consequent expected decrease in units sold per lighting consumer, has made the question of the cost of house service connections to small consumers one of considerable importance.

The cost of a service connection depends, of course, on its length and on the demand of the consumer. Fortunately, as a rule, the smaller the demand of any lighting consumer the cheaper is his service cost. This is because a small house generally stands back only a short distance from the street, and a small section of cable, and a meter and fuses of only small capacity are required to supply it. Thus shops with a frontage on the street, houses with a basement, flats, "flatted villas," and rows of cottages can all be connected up quite cheaply; it is villas and houses standing well back from the street that are expensive to connect, but these are generally, from the station point of view, among the best lighting consumers.

The writers believe that a draw-in system of mains can be shown to be the cheapest to connect house services from, as well as the all round cheapest for other reasons. It is somewhat remarkable that, in discussions on central station design and costs, the design of the generating station is minutely elaborated, whereas the distribution system is generally dismissed as costing so much per kilowatt, without any particular system of laying the cables being specified. It can, however, be shown that the first cost and the maintenance of any distribution system, considered as a whole, are greatly modified by the system adopted.

The cost of services are much influenced by the position the supply authorities' fuses and meter are made to occupy. Discretion should be used, when deciding their position, to ensure that they shall be free from moisture, and that the apparatus shall be reasonably safe from mechanical injury. Considerable tact is often necessary to convince a consumer that the most desirable position from the supply authorities' point of view is also the best for him. An authorised authority is not legally bound to carry the service lines beyond the boundary wall of a consumer's premises. Most corporations have a free limit, up to which service lines are carried in free, but above which the consumer has to pay for the extra distance. This free distance might with advantage be reduced in some cases, so as to cheapen the average house service costs.

Service-leads off a draw-in system must be led from an accessible box built on the ducts. Such a box may be built of brick lined with cement, and having a cast-iron frame, and preferably hinged, drained, and ventilated lid, filled up with concrete. The hinging of the cover on to the frame, and the draining of the latter, has been found very satisfactory with ventilated box covers. If the ducts are laid in the pavement, such a box (about 15 ins. by 15 ins. inside) can be installed complete for about 18s., including mason's time for building, and checking pavement, bricks, cement, sand, and frame and cover.

The whole of this cost, which in unfavourable circumstances should not be greater than 20s., is, of course, not borne by one consumer. The box is always built opposite the parting wall dividing two sets of premises, so that half the cost only belongs to any one service (except in the case of isolated consumers). Further than this, in many cases the cost may be divided among as many as eight consumers. This is the case when a supply is given to a tenement building, there being six consumers living in flats on the common stair, and two ground floor houses on each side of the stair, each with independent access. To supply such a building then, one box is built, one pipe led into the common stair, one concentric service cable pulled into the pipe, and one pair of main fuse boxes put up. The owner of the property runs a pair of mains up the stair from the main fuses, supplying sealable fuses for each consumer on their respective landings. Each consumer has his meter inside his flat. Putting the cost of the box at 20s., the pipe (galvanised iron) at 20s. installed, the cable (lead-covered concentric) at 12s., the fuse boxes at 7s. 6d., jointer and mate's time at 4s., jointing material 2s., cartage 1s. 6d., the whole cost, exclusive of meters, is £3 7s. Divide this by eight, add cost of meter (30s.), and cost of testing, &c. (say), 1s., and the cost per consumer works out at rather less than £2.

It will be seen that if this service were put in to supply a single consumer, the cost would be, using a bigger meter, about £5 10s. But, as pointed out, one box can nearly always be made to serve at least two consumers, and small cottages, shops, town houses, and any premises with a frontage on the street, will probably require a shorter length of pipe and cable than allowed for above; indeed, where the service line can be led into a cellar or an area the actual length of line is often only three or four feet. The cost of a service may then be anything from £2 up to £6, and if consumers requiring long services are made to pay for the additional length, the average cost per service should be well under £6, and considering small consumers only, the writers consider that between £3 and £4 is a fair average.

Suppose the service cost of a small consumer is as much as £5, if interest, sinking fund, and depreciation charges on the service cost amount to 10 per cent. per annum, this means an annual charge of 10s. to be borne by this service. Now the class of consumer here considered, whose total service cost, including meter, may be as low as £2, will in general use chiefly one room, which may be lighted by one or two lamps, but he will be a good long hour consumer, and will use perhaps 100 units in a year; at 3d. per unit, this equals 25s. Deducting 10s. for the cost of his service, this leaves 15s. to pay for his proportion of the station standing charges, and running costs on 100 units. Now ½d. per unit is certainly not too little for the running cost, therefore, deducting 100 units at ½d. = 4s. 2d. from 15s., leaves (say) 10s. for standing charges.

Ten per cent. is a liberal allowance for interest, sinking fund, and depreciation. The life of meters has been recently estimated by Mr. R. Hammond at 10 years, by Mr. J. F. C. Snell at 15 years, and by Sir William Preece at 12 years, but there seems no reason why some meters should not have a much longer life.

The type of house-service fuse-box allowed for in these estimates consists of two 3 ins. break single-pole fuses, enclosed in separate cast-iron boxes, lined inside, and mounted on varnished wood board.

It will be noticed that the cost of the material used for the actual service joint is only 2s. This represents solder, resin, wax, bitumen lapping, proof tape, and benzine. The whole joint is suspended in air in the manhole, and can be made perfectly sound with a good wax and proper lapping. Since there is no lead sleeve over the joint, the lead of the distributors off which the service is tapped is necessarily broken, unless a bond be put on round the joint. The distributors are supposed to be single cables. The writers regard it as an advantage to break the continuity of the lead covering

Digitized by Google

at any such joints. The joint is every bit as good as the elaborate sealing boxes often used for lead-covered fibrous insulated cables; the outside tapes can be regarded as taking the place of the porcelain or metal box into which the cables are sealed with wax, the wax, in the case of the joint, being replaced by wax and lapping, which, if put on properly, form a homogeneous mass, equally as adherent as wax alone.

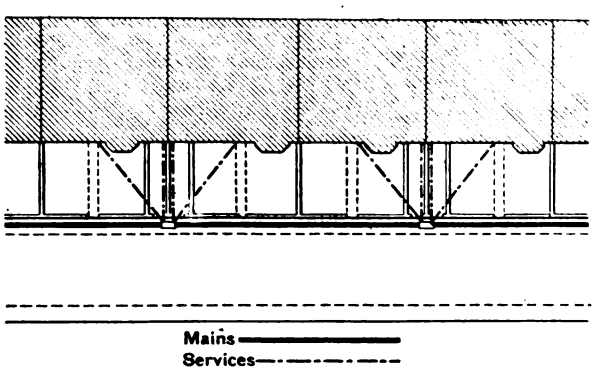

Fig. 1.—Sketch showing Eight Services to "Flatted Villas," from Two Service Boxes.

There are many special cases in which services may be cheapened; for instance, it is often possible to supply two consumers from one service pipe. Two single cables are better than a concentric cable in this case. The fuse-boxes of each consumer are placed back to back one on each side of the dividing wall, and a tapping taken through the wall. This method is, of course, only applicable to a limited number of services, and is not always to be recommended. Within recent years in many suburban districts, small houses built on the "flatted villa" principle, where each tenant has a separate front entrance, have come into fashion. Service costs to this class of property average out higher than the tenement consumer already quoted, but it is possible that economies may be effected if a draw-in system of mains is employed, in which case four services may be tapped on to the mains in one manhole, see Fig. 1.

In such cases as the above it is found cheaper to substitute an armoured concentric service cable, laid direct,

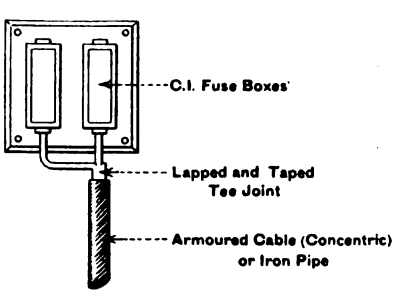

Fig. 2.

in place of the ordinary concentric cable drawn into a galvanised iron pipe.

Provided a good position has been selected for the fuses to be fixed, it seems to be quite unnecessary to use a cable-sealing chamber in conjunction with the fuses. A system of splitting the concentric cable below the fuses, as shown in Fig. 2, has given satisfaction, and has the advantage of low cost.

In many residential districts it is frequently found more efficient to lay distributing mains on one side of the road, only crossing to the opposite side as required, with services as shown in Fig. 3.

Several attempts are being made to dispense with meters for small consumers, a charge per lamp installed per annum being made. In these cases, however, a consumer is generally very generous in his consumption of energy. Blocks of offices can be supplied through a main meter, for which the landlord is responsible, including the use of light in the rent. Such consumers are horribly bad from the station point of view, and are certainly not worth a meter each; if insisted on a meter rental should be charged.

Attempts have also been made to cheapen service costs by running distributors through blocks of houses, either under the floors or under the roofs. In such cases it seems probable that an attempt would be made to hold the supply authority responsible for any fire that breaks out.

The invention of a good cheap meter would considerably simplify the problem of supplying small consumers.

Low watt lamps should have a directly beneficial effect in reducing the maximum demand of the unprofitable short hour consumer, and cannot attract many

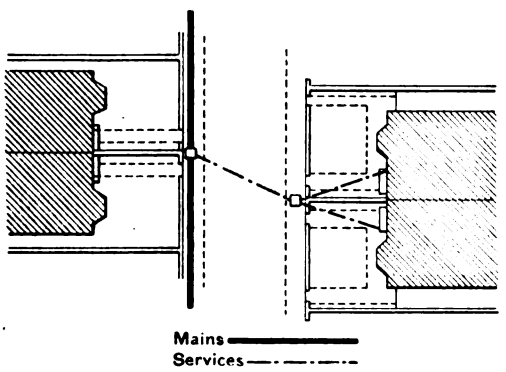

Fig. 3.—Sketch showing Mains Laid on one side of Road with Service Crossing to the Other Side.

more of this undesirable type, because they are nearly all connected already, at any rate where a flat rate charge is in force.

New Telephone Charges.—At a meeting of the Liverpool Chamber of Commerce last week it was decided to support a resolution of the London Chamber of Commerce to the effect that the Permanent Telephone Committee of the Association of Chambers of Commerce of the United Kingdom be dissolved, as not having the confidence of the Association. It will be remembered that this Committee was formed a few months ago for keeping in touch with the Postmaster-General and the National Telephone Co. on matters relating to the telephone service throughout the country, and especially with regard to the new system of charging.

Electrical Power in Australian Mines.—The *Australian Mining Standard* states that following the success of the earlier portion of the electrical equipment of the Mount Lyell mines, a contract has been placed for an electrically-driven air compressor with a capacity of 2,000 cubic feet of free air per minute and a final pressure of 80 lb. per square inch. This represents the application of electricity for compressing purposes on a far larger scale than anything previously undertaken in Australasia. Some new pumping plant is also on order. The North Lyell mine was the first in Australia to install an Ilgner main electrical winding plant. The new compressor will be of the two-stage type, manufactured by Messrs. Thompson & Co., of Castlemaine (V.), and will be driven at a constant speed of 144 r.p.m. by an A.E.G. three-phase induction motor, 350 h.p., 3,000 volts, mounted direct on the shaft between the high and low pressure cylinders. As the output of the compressor cannot be economically altered by varying the speed of the motor, an automatic mechanical device will be provided, which will cause the compressor to run light immediately a predetermined maximum pressure is reached in the receiver, and again run fully loaded as soon as the receiver pressure has fallen a few lbs. below normal. The motor will be controlled by a liquid starter. The new pumping plant consists of four Pearn treble-ram electric mine pumps, each with a capacity of 6,000 gallons per hour, against a vertical head of 400-450 feet. The whole of the castings, valves, valve seats, plungers, &c., coming in contact with the water, will be made of high-grade gun metal, to resist the excessive corrosive nature of the mine water. Two of the pumps will be placed about 700 ft. below the top of the shaft, and the other two 450 ft. lower. The pumps in each chamber will be placed over the well, and will be automatically stopped and started by A.E.G. patent float controllers. The motors driving the pumps will be of the three-phase slip ring induction type, having a normal rating of 25 h.p. at 525 volts, but will be capable of running continuously, if necessary, at 30 h.p. The efficiency of the pumps is guaranteed at 80 per cent., and that of the motors at 89 per cent.

REVIEWS OF BOOKS

Power Gas Producers. By Phillip W. Robson. 244 pages 5¼ in. by 8½ in.; 105 illustrations. (London: Edward Arnold.) Price 10s. 6d.

This book is divided into three sections; the first deals with general principles, with the chemical reactions involved, and with suction gas producers; the second and third describe pressure producers for non-bituminous and for bituminous coal respectively. In each section the theory of the subject is first indicated, and then the manner in which it is more or less applied by various manufacturers is discussed. The admittedly difficult subject of the chemical reactions occurring in a producer is described in a lucid manner to an extent sufficient to enable an engineer to grasp the theory on which gas producers are built. A numerical example is worked out in considerable detail, and will greatly assist the reader in understanding the chemical principles involved. The author lays great stress on the amount of steam blown into the producer; he shows that there should not be more than 0·8 lb. of steam per lb. of fuel, and that since this is equivalent to saturation at an air temperature of 85° Fahr., it is easy to have too much steam, because the pre-heated air has a temperature of about 160° Fahr. If, therefore, the vaporiser is not carefully arranged and the water supply duly regulated, the amount of steam may be excessive, with the consequent lowering of the furnace temperature, resulting in inferior gas. For this reason, amongst others, he prefers the "flash boiler" type of vaporiser to those in which there is practically an unlimited supply of water.

In Chapter III. the essential features of a suction producer are described, such as the furnace, the vaporiser, and the firegrate, and the merits and demerits of the arrangements adopted by various manufacturers are discussed in a most impartial manner. We desire to emphasise this point, because the author is connected with the National Gas Engine Co.; this has not, however, in our opinion, affected the impartiality of his judgment. The construction of generators is dealt with in Chapter IV., and it is stated that up to about 100 h.p., cast-iron is the most suitable material for the bodies; beyond this size rivetted steel plates are best. The author favours cast-iron in all cases for the vaporisers (on account of corrosion), a view which will not receive universal acceptance. Special attention is called to the importance of making a good job of the fire-brick lining of the furnace, and specially shaped fire-brick lumps giving radial joints are recommended. The object, of course, is to prevent air leakage into the upper part of the furnace. A great number of suction producers are illustrated and described.

The function and design of scrubbers, fire-bars, and grates, and other important details, are considered in Chapters V. and VI. An interesting calculation is given whereby the amount of cooling water required in a scrubber is obtained—it comes out to just over one gallon per B.H.P. It is also explained that the temperature of the water at the outlet must not exceed 130° F., else vapour is produced which tends to carry forward the tarry matter and dirt in the gas. Suction plants for bituminous fuels are exemplified by the Deschamps producer, and the Fichet and Heurtey producer—they are both on the down-draught principle. The author is sceptical as to practical use of such producers, because the complexity of the apparatus for cleaning the gas, and the difficulties arising in the gas engine itself, lead to greater expense than the saving in the cost of fuel. Moreover, the probable solution will be the coking of such bituminous fuels to obtain the bye-products on a large scale, the resulting coke being suitable for ordinary suction producers. In the next chapter much practical information and many useful hints are given as to working and management of producers, and in the following chapter various causes of trouble are mentioned, and information is given as to how to detect and remedy them. The last two chapters of Section I. contain several examples of the practical application of suction plants, and information as to working results in respect of fuel and consumption. According to the author, the only authoritative comparative tests are those which were carried out by the Royal Agricultural Society, at Derby, in 1906. He also quotes tests made by Mr. R. E. Mathot on a Tangye plant. These tests are most instructive, and show a fuel consumption as low as 0·71 lb. of anthracite per hour.

Pressure producers for non-bituminous fuel are dealt with in Chapter II. (Section II.), and, since the chemical reactions are the same as in suction producers, only the points of difference are considered, such as the separate steam boiler and the steam and air injector for producing the pressure. Several examples of application to practice are given. There is also a short description of the Dellwik-Fleischer water-gas producer, which requires to be alternately blown with steam and air, and depends on the fact that when the velocity of the air over the glowing carbon is high, CO_2 is formed instead of CO.

The last chapters, 13 to 15 (Section III.), are devoted to pressure producers for bituminous coal, and give some particulars in connection with the recovery of ammonia with the Mond plant. Attention is called to the large amount of steam required for this process, which is three times greater than the best theoretical amount, a point which is confirmed by the experiments made in 1906 on a Mond plant by Messrs. Bone and Wheeler; these experiments are given in some detail. This large amount of steam is, however, necessary with coal, but with peat the proper amount of steam can be used, because the moisture in the peat keeps the upper layers at the proper temperature for distilling the bye-products. The author does not refer to this point, but his prophecy that peat producers may be an important *future application* is already fulfilled. The book concludes with a description of the various methods of washing and cleaning the gas; we note that the Theissen washer, which is much used in Germany, is not mentioned.

We can fully recommend this book to any engineer who wishes to become acquainted with the extremely important subject of power gas producers.

The Post Office Electrical Engineers' Journal. A Quarterly Journal. Vol. I., Part II.; 84 pp., 9¾ in. by 6 in. (London: H. Alabaster, Gatehouse & Co.) Price 1s. net.

The excellent quality of some of the articles in the second issue of this quarterly, and the fact that it has the support of the Engineer-in-Chief to the Post Office, who has contributed some notes on the education of telegraph engineers in France, makes us lothe to criticise the policy of this enterprising institution in regard to its journal. Yet there are two matters to which attention has already been drawn, and upon which we consider it our duty once more to comment in an adverse sense. Although presumably the services of the editorial staff and contributors are given gratuitously—whether by themselves or by their employer, the Post Office, it is perhaps unnecessary to ask—a further subsidy is apparently required to enable the journal to be published, and this is supplied by a certain number of manufacturers of telegraph and telephone material and stores whose advertisements are inserted in the journal nominally as a *quid pro quo*. In all probability the committee of Post Office engineers who conduct the journal does not receive these payments directly, but whether a definite sum is paid to them for each advertisement, or whether the profit is derived as a set-off

Digitized by Google

to the price paid to the firm who print and publish the paper does not affect the principle, which is an extremely bad one. Advertisements of material and plant of a nature that is purchased by a Government department should be rigorously excluded from a newspaper belonging to the staff whose duty it is to recommend the placing of orders and to make the reception tests of the material purchased.

The second matter in which the proprietors of this new publication have departed unwisely from precedent is in the contents of the journal itself. As a rule, the contents of an institution's "journal" consist of full reprints of the Papers read before the institution and full reports of the discussions at its meetings. Instead of these forming the main contents of the journal, they are deliberately omitted.

The present issue includes articles on a motor-driven Wheatstone transmitter, the design of telegraph and telephone cables, pneumatic tube joints, pot heads, the Richmond telephone exchange (a full C.B. exchange replacing a "C.B.S." exchange), &c. It is surprising to find, in addition, no less than three serial articles in a magazine published only at three monthly intervals, and a highly mathematical article, "On the Propagation of Plane Electromagnetic Waves along a Plane Conducting Surface, and its Relation to Wireless Telegraphy," is particularly unsuitable for this treatment. To the article by the Engineer-in-Chief we have already referred; the printers should be informed that his name is O'Meara, and not Omeara.

MANCHESTER CORPORATION TRAMWAYS ACCOUNTS

IN the report which accompanies the accounts of the Manchester Corporation Tramways for the year ending March 31st, 1908, it is stated that during the year under consideration additions and extensions amounting to over seven miles of single track have been opened for traffic. The aggregate length of single track open for traffic (including the lines over which the Corporation are exercising running powers) is at present nearly 177 miles. The number of cars in stock at March 31st, 1908, was 566. This included 309 single-truck cars, 115 with covered tops, and 194 without; 87 double-truck cars, 125 with covered tops and 87 without; and 45 other cars. About 6½ acres of land have been purchased as a site for a new car-shed, which will accommodate, when complete, 250 cars. The population served by the tramways is approximately 850,000. The number of passengers carried during the past year was 151,477,138, as against 143,264,501 in the previous year. The number of car-miles has increased from 15,523,459 to 16,974,955. The working expenses per car-mile (including power cost) amounted to 7·07d., or 65 per cent. of the total receipts. The following is an analysis of the working expenses and capital charges:—

Analysis of Expenses per Car Mile.

	Year ended Mar. 31, 1907.	Year ended Mar. 31, 1908.
	d.	d.
Traffic expenses—		
Salaries and wages	2·310	2·289
Cleaning cars and depot expenses	0·420	0·450
Cleaning, salting, and sanding track	0·044	0·043
Ticket check	0·150	0·154
Uniforms	0·088	0·084
Miscellaneous	0·028	0·030
	3·040	3·040
General expenses—		
Salaries and wages	0·161	0·150
Rent, rates, and taxes	0·530	0·510
Insurance, law, and other expenses	0·146	0·229
Miscellaneous	0·143	0·109
	0·980	0·998
Repairs and maintenance—		
Permanent way	0·143	0·190
Electrical equipment of line	0·110	0·106
Cars and electrical equipment	0·660	0·660
Buildings and miscellaneous	0·067	0·056
	0·980	1·012
Power expenses—		
Cost of current at 1·143d. per unit.	2·030	2·020
Total costs, excluding capital charges	**7·030**	**7·070**
Rental of leased lines, &c.	0·392	0·317
Interest	0·774	0·690
Sinking fund	0·610	0·590
Income tax	0·074	0·087
Expenses of 1907 Bill	—	0·068
Reserve, renewals, and depreciation fund	1·355	1·240
	3·205	2·992
Total costs, including capital charges	**10·235**	**10·062**
Total receipts per car mile	11·120	10·870

The following additional figures are of interest:—

	1906–7.	1907–8.
Electrical energy—Total number of units used	25,072,791	29,955,070
Electrical energy—Number of units used per car mile	1·61	1·76
Percentage of working expenses to receipts	63·18	65·00
Average traffic revenue per car mile	11·02d.	10·76d.
Average traffic revenue per mile of single track	£4,556	£4,640
Average car miles per day per car	100	98·5
Average fare paid per passenger	1·19d.	1·21d.
Average number of passengers per car mile	9·23	8·92
Average journeys per head of population per annum	179	178

It will be noticed that the traffic receipts per car-mile have gone down from 11·02d. to 10·76d. This is mainly attributable to the inclement weather experienced during the whole of the year. The working expenses have been increased by 0·04d. per car-mile. This is accounted for by a large increase in the cost of compensations and a slight increase in the cost of the maintenance of the permanent way, which is unavoidable as the track gets older. The total working expenses amounted to £500,023, and the receipts from all sources reach the figure of £771,176 (including £1,220 from the parcels' department and £2,103 for interest on surplus revenue). Of the balance of £271,153 thus given, £22,427 was required for rental of leased lines; interest, sinking fund, and income-tax absorbed £49,035, £41,749, and £6,197 respectively; £4,847 was required for Parliamentary expenses; and £87,790 was transferred to reserve, renewals, and depreciation fund. The surplus of £59,108 was divided as follows:—£55,000 was contributed in aid of rates, and £4,108 was expended on street improvements.

The following is an analysis of the net capital expenditure on the undertaking as at March 31st, 1908:—

Permanent way	£607,476
Electrical equipment of line	174,705
Land	67,932
Buildings and fixtures	234,244
Rolling stock	357,243
Machinery and plant	9,740
Cost of Carriage Company's undertaking	277,492
Miscellaneous	47,797
	£1,776,629

Manchester Local Section of the Institution of Electrical Engineers.—The annual report of the committee of the Manchester Local Section of the Institution of Electrical Engineers has just been issued. During the last session ten meetings have been held, the discussions at which have been reported in our columns from time to time. The average attendance at meetings has been well maintained, and considerable interest has been shown in the Papers, which have covered a wide field. The membership of the section is 787, including 339 students, which is an increase of 47 over last year. The report of the students' section, which has held ten meetings and made nine visits to works, is issued separately.

LONDON AND DISTRICT ELECTRICITY SUPPLY BILL

THE second reading debate upon the London and District Electricity Supply Bill took place in the House of Commons on Thursday.

Mr. CHAPLIN (Wimbledon) moved the rejection of the Bill in order to obtain the exclusion of Wimbledon and Merton. Mr. T. DAVIES (Fulham) and Mr. PICKERSGILL (Bethnal Green) supported the motion for the rejection of the Bill, for the reason that they objected to the creation of a monopoly with competitive powers against the existing municipal undertakings. The latter gentleman remarked that it was proposed to create a company with a capital of £4,500,000 to sell electrical energy in bulk and detail, not only in London, but in an enormous area around London; the company was to be authorised to tear up the streets and lay mains, to abstract 200,000,000 gallons of water daily from the Thames, and to carry their cables through the Blackwall and Rotherhithe tunnels of the London County Council, whether the latter liked it or not. So grotesque a scheme was never conceived outside the domain of Gilbertian opera. Other speakers, following on the same line of argument, and who opposed for the reason that their constituencies were included in the area of the Bill, were Mr. ROWLANDS (Dartford), Mr. CAVE (Kingston-on-Thames), and Mr. CROOKS (Woolwich).

Mr. MCKINNON WOOD said the matter had been referred to as a very simple one indeed, but he did not know of a more complicated subject than the present position of electric power supply in London. Whilst holding no brief for the power company, he felt bound to point out that the prices proposed in the Bill were the lowest ever inserted in such a Bill, and it should also be remembered that the London County Council refused to carry out a scheme itself. Personally he would prefer a complete municipal scheme, but this year there was no possibility of a municipal Bill, and he was not justified in voting against the Bill and so bringing about further delay. He did not approve of the terms of purchase, but these could be argued in Committee. With regard to competition, these powers were carefully safeguarded, and although there had been no whisper of opposition to the proposals of existing companies with regard to linking up, he was of the opinion that without a bulk company such as this, they would hear of no more cheap electricity, so far as the existing companies were concerned, once the linking-up powers were granted. The Borough Councils had taken a purely parochial view in their opposition to the Bill, and had not regarded the matter from the point of view of London as a whole. The London County Council was continually receiving applications from the Borough Councils for capital to extend their generating stations, which were in most cases inadequate, too small for economic working, and too badly placed to supply cheap electricity. A cheap bulk supply was the only remedy for this state of affairs, and he should therefore vote for the Bill.

Mr. DICKINSON (St. Pancras) expressed the opinion that if the Bill went to a Committee, with the instructions that the London County Council should be the purchasing authority, it would come back to the House in such a form as would enable the public to enter into their rights. This was the first time a bulk supply Bill had included a purchase clause.

Mr. BURDETT-COUTTS (Westminster) referred to the special circumstances in his district, which were fully gone into before Lord Cromer's Committee, and was concerned as to the effect of the Board of Trade's proposed clause upon the special clause given to the Westminster City Council by Lord Cromer's Committee.

Sir JOHN BENN supported the view of Mr. McKinnon Wood, and said that those who voted for the rejection of the Bill would really be retarding municipal development.

Mr. FORSTER (Sevenoaks Division of Kent) opposed the second reading for the reason that part of his constituency was scheduled in the Bill, and would come to some extent under the control of the London County Council eventually, a position which they did not wish to be in.

Mr. WINSTON CHURCHILL, President of the Board of Trade, referred to the opposition to the second reading as an "unholy alliance," consisting as it did of Labour members, Unionists, and Liberals, a strange combination, he said, to fight for the interests of London. Although they were only discussing one Bill, the Board of Trade intended to ask the House to apply a common policy to all three. This was to afford every facility to develop electrical supply in London, and to transfer it at the earliest possible moment to the London County Council. With regard to the present Bill, this promised to give a supply of electricity at the lowest price ever put into such a Bill; there was compulsion to supply, there was limitation of dividends by a sliding scale, and there was provision that the powers should lapse unless £600,000 was subscribed in the first year, and substantial progress made with the works by the second year. In addition, by sending the Bill to Committee, there would be a thorough inquiry as to whether the terms of the Bill as a whole were satisfactory. The Board of Trade did not approach this matter from the party point of view. They had to have regard to the greatness of London, with its 6,000,000 people, living under conditions of highest artificiality, and they saw that cheap electricity was scarcely less important than cheap and abundant food. This was the fifth successive year in which attempts had been made to pass such a scheme, and the uncertainty had hung like a pall all the time over the electrical industry. The initiative of private promoters had been seriously discouraged; meanwhile municipal enterprise had not advanced to fill the gap, and there was no immediate prospect of it so doing. In the view of the Board of Trade, therefore, the House of Commons would take a very grave responsibility if it disregarded the elaborate proposals now put forward without giving them the most detailed attention which only an impartial Committee of the House of Commons could give. A Committee of the House of Commons went into the question in great detail two years ago, and decided that the need for a bulk supply scheme for London was important and pressing.

Mr. LYTTELTON, representing St. George's, Hanover Square, which is within the City of Westminster, stated that the proposal to transfer to the London County Council all the powers of purchase now possessed by the Westminster City Council, could not be accepted.

The debate was closured at 11 p.m., and the amendment in opposition to the second reading of the Bill was rejected by 48, the figures being:—For the amendment, 90, against 138.

The Bill was then read a second time.

STANDARDS FOR ELECTRICAL APPARATUS

A Comparison of British, American, and German Rules

THE following comparison of the standardisation rules of the British Engineering Standards Committee with those of the American Institute of Electrical Engineers, and the Verband Deutscher Elektrotechniker, is taken from an article by Mr. J. S. Peck, in the *Electric Journal* (Pittsburg).

A comparison of the standard rules issued in Great Britain, Germany and America is of considerable interest as showing the views of engineers in the different countries as to safe operating conditions. The temperatures, overloads, and testing voltages called for in the standard specifications of the three different countries are given in Tables I., II., and III. The indicated temperature instead of the rise in temperature is given, as this is really the value which determines the rate of deterioration of the machine. In America and Great Britain, the temperature rise is given above a room temperature of 25 degrees C., while in Germany a room temperature of 35 degrees is permitted. This in itself adds ten degrees to the allowable working temperature under German conditions.

In the German rules, different temperature rises are permitted for different classes of insulation. Cotton insulation demands the lowest temperature, paper insulation comes next, with about ten degrees higher rise, while mica, asbestos, and similar insulating material is permitted a temperature about thirty degrees higher than is allowed for cotton insulation. In the British and American standards it is stated that where special heat resisting insulating material is used, higher temperatures may be allowed than with the ordinary insulating material, but no limits are given. This distinction in permissible temperature rise for machines insulated with different kinds of material seems a step in the right direction, for there is no reason why a machine insulated with asbestos and mica throughout should be operated at as low a temperature as a machine insulated with cotton and similar perishable material. The great danger in this classification appears to be in the opportunity it offers for fraud; on account of the inability of the customer to determine whether all of the insulation in a machine is really of a fireproof nature or not. Everyone familiar with the insulation of electrical apparatus knows that many of the so-called fireproof insulating materials are anything but fireproof, and while it is not likely that responsible manufacturing companies who have had wide experience with different classes of insulating materials will put out apparatus which will not give a reasonable life, there is the possibility that manufacturing companies with less experience may be tempted to operate at higher temperatures than the insulating materials will stand. It is not probable that any conservative British or American engineer would ever

Digitized by Google

accept electrical apparatus operating at a temperature of 125 degrees, regardless of the class of insulation employed, and it is doubtful whether many German engineers would accept such machines. Nevertheless, this temperature is permitted by the German rules with certain classes of insulating material.

Table I.

Maximum Operating Temperatures of Electrical Apparatus, as Specified by the Engineering Standards Committee of Great Britain, the American Institute of Electrical Engineers, and the Verband Deutscher Electrotechniker.

	American.		British.		German. Cotton.		Paper.		Mica.	
Part of Machine.	T*.	Rt.	T*.	Rt.	T*.	Rt.	T*.	Rt.	T*.	Rt.
Windings, stationary	75	75	—	85	—	95	—	105	—	125

Table III.

Insulation Tests.

	American.	German.
Minimum testing voltage	1000 for one min.	100 for 30 mins.
Apparatus for voltages between 5000 and 10,000	Double for one min.	Normal + 5000 for 30 mins.
Apparatus for voltages over 10,000	,, ,,	Normal + 50 % for 30 mins.

In general it may be stated that the American standards are much more conservative than the German, while the British standards come somewhere between the two, but are nearer to the American than to the German. In Europe, the keenness of the competition in the sale of electrical machinery has made it necessary for manufacturers to take advantage of every possible means for reducing the cost of their apparatus.

ELECTRICAL ENTERPRISE IN RIO JANEIRO

SOME particulars of the operations of the Rio de Janeiro Tramway, Light & Power Company are given in a recent Consular report. This company, which is registered in Toronto, has been operating here since 1905, and has practically, March, 1908, completed its hydro-electric installation on the River das Lages, in the State of Rio de Janeiro, about 51 miles from the city. The works, which are said to comprise one of the most complete hydro-electric installations yet constructed, include a concrete dam 110 ft. high and 700 ft. long on the top, creating a reservoir with a capacity of 221,000,000 cubic metres of water. From this reservoir the water is conducted to the power station through steel pipes a distance of about 7,420 ft., the fall in this distance being about 1,080 ft. The power station, which is located on the river, is of steel construction, with concrete walls for the lower portion and brick for the upper, the dimensions being 232 ft. long by 102 ft. wide between the main columns. There are six wheels of 9,000 h.p. capacity each for the generators, and two wheels of 400 h.p. capacity for the exciters, all of the impulse type. These transformers are of the oil- and water-cooled type. The transmission line, which is 51 miles in length, is located upon the private right of way of the company in its whole extension, the width varying from 132 ft. in Rio de Janeiro to 300 ft. in the country districts of the State. The power is received over four circuits suspended on two lines of steel towers, 1,052 in number, in the whole distance between the power station at Rio das Lages and the terminal station, which is situated at Rue Frei Caneca in the city. This terminal station is of steel construction, with concrete walls for the lower portion and brick for the upper, the dimensions being 243 ft. long by 133 ft. wide. The distribution system of the three-phase 6,000 volts leaving the terminal station is in the suburbs made by aërial lines suspended on iron poles, and in the central part of the city with branches to all the populous districts by underground lead-covered cables. For the purpose of the underground work there has been built a network of conduits, of which, up to the present, there have been laid over 1,400,000 lineal feet, connected with 74 subterranean transformer vaults. For the service of the works the company has constructed a railway 16½ miles in length, connecting the Central, or Government, Railway with its power station at Rio das Lages. To provide power for construction purposes and for use in Rio de Janeiro pending the completion of the large power station, a temporary plant of 3,400 h.p. was installed. The energy produced at this installation was used for the illumination of Rio de Janeiro and vicinity, as also for the operation of the street-car systems, factories, &c., pending the completion of the permanent power-house. As all coal is imported, the cost of steam power in the city is very high. The company estimate this steam power now in use to be at least 20,000 h.p., which they expect to be replaced by electrical power within a few years. This is exclusive of the amount which will be required for electric lighting and tramways. In addition to the Rio das Lages power, which will have a maximum capacity of 50,000 h.p., the company has obtained a concession from the State of Rio de Janeiro to divert the waters of the River Pirahy, which flows in a valley adjacent to that of the Rio das Lages. The amount of the water flowing in the Pirahy is much greater than that in the Lages, and by means of the use of the flood waters of that river with the power of the Rio das Lages, the capacity can, by an extension of the power station, be increased to 100,000 h.p., or even more if required. This diversion can, it is asserted, be made at comparatively small expense, by the construction of a small dam and a tunnel about two miles in length.

The company, either by concessions made to it directly, or by subsidiary companies controlled by it, exploits the following public services.

The company is the owner of the share capital of the Companhias São Christovao, Carris Urbanos and Villa Isabel, which provides about three-quarters of the tramway service of Rio de Janeiro, under concessions from the municipality of the Federal District. By a contract made in the month of November, 1907, with the municipality, these concessions were consolidated and extended until the year 1970; the Rio de Janeiro Tramway, Light & Power Company undertaking to electrify them within a period of about three years and construct about twenty miles of new lines. The lines of the Villa Isabel are already electrified, and the work of transforming the traction of the other companies is commenced.

The Société Anonyme de Gaz de Rio de Janeiro, a Belgian company, acquired by the Rio de Janeiro Tramway, Light & Power Company, controls the whole of the illumination of the city by gas and electricity in virtue of a concession from the Federal Government to 1945, with monopoly to 1915. All parts of the city are now illuminated by gas, the electric lighting being confined for the present to the new avenues recently opened and the central commercial section. It is expected that during the present year the electric lighting will be greatly extended.

The company, by virtue of a concession from the municipality of Rio de Janeiro, enjoys monopoly for the distribution of electric power, produced in an hydraulic installation, until the year 1915, and thereafter the right continues without monopoly until the year 1990. At the present time only about 3,000 h.p. is furnished for use, but now that the permanent installations of the company are practically completed, they expect within a few months to greatly increase this, as many factories now using steam power seem ready to change it for electric.

The telephone concession, which was formerly exploited by a German company, recently acquired by the Rio de Janeiro Tramway, Light & Power Company, gives exclusive right for telephones in the Federal District. The system has been recently largely reconstructed, the building where the installation is situated, which was recently destroyed by fire, having been rebuilt and installed with a new central energy telephone board of the most modern design. There are now about 2,500 subscribers, and the company expects within another year to increase this to the full capacity of the present board, which is 5,000. In addition to the reconstruction of the building and installation of the new switchboard, all of the subscribers' instruments have been changed for improved instruments. The street circuits have been rebuilt, and a large amount of aërial cables has been installed to take the place of the network of overhead wires in the streets, thus greatly improving the service. A large part of the system is in underground cables, and it is expected that this will be extended from year to year, until all overhead wires in the populous districts have been removed.

ELECTRICAL EQUIPMENT AT THE FERNDALE COLLIERIES

THE advantages to be obtained by the use of electricity in mining are being realised at an increasing rate by colliery proprietors in Great Britain, and already a large number of coal mines, especially in the South Wales district, have completed or have under construction electrical equipments of considerable magnitude. An interesting example is to be found in the group of pits belonging to Messrs. D. Davis & Sons, in the Rhondda district, known as the Ferndale Collieries. These comprise nine pits in all, situated fairly close together, for the supply of which the colliery owners have constructed a large steam-driven generating station. Electrical power is used for ventilating, pumping, and for extensive underground haulage, and a complete main shaft electrical winding engine is being erected at one of the newer pits. There is, of course, a good deal of electric lighting both above and below ground, and the greater part of the surface machinery, screening plants, &c., is electrically driven. The change over to electric power is still proceeding, but already a considerable load is taken from the power station. Electric haulage was practised in the mines pending the completion of the company's own supply arrangements, and current was taken from the South Wales Power Company's system; owing to this fact the supply has been developed on the three-phase 25-cycle system.

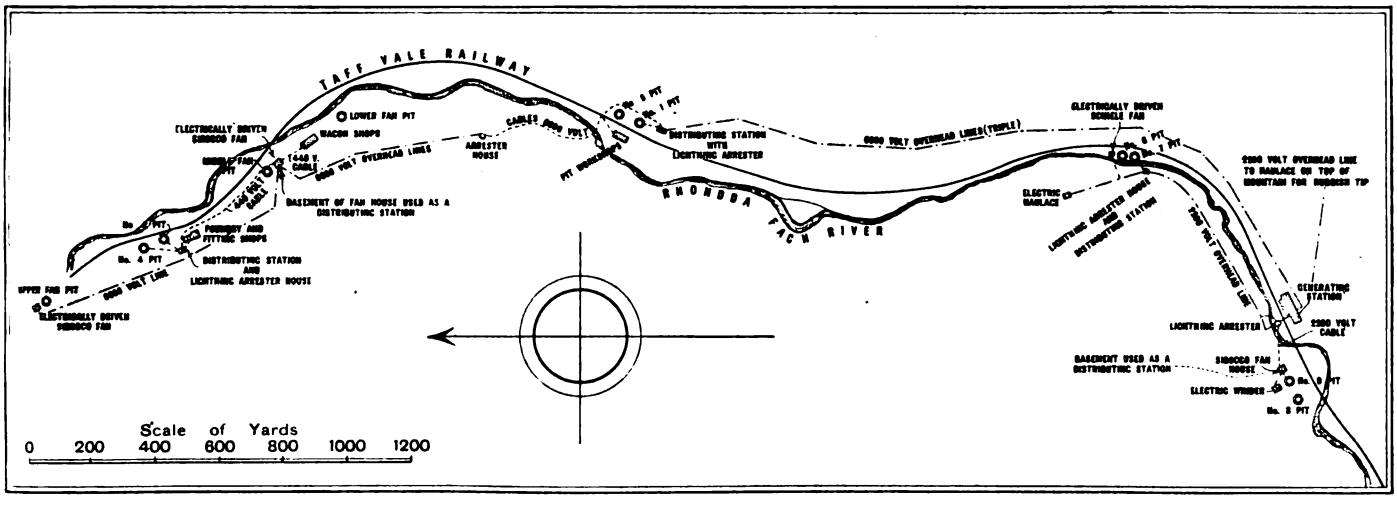

FIG. 1.—GENERAL PLAN OF FERNDALE COLLIERIES, SHOWING POSITIONS OF PITS, GENERATING STATION, SUB-STATION, TRANSMISSION LINES, &C.

A general idea of the extent of the collieries and supply system can be obtained from the sketch plan in Fig. 1. The power station adjoins the Taff Vale Railway Co.'s line at Tylorstown, and is close to the new "No. 9" pit, where the electric winder is being installed. By the side of this pit is the No. 8 pit, and about 900 yards away are Nos. 6 and 7 pits. Nos. 1 and 5 pits are at Ferndale itself, about 2,500 yards distant; and some 2,000 yards further up the valley are Nos. 2 and 4 pits. All these pits are in the "Rhondda Fach" valley, supplied from the Tylorstown power station; but the remaining pit, No. 3, which is situated at Bodringallt in the adjoining "great" Rhondda valley, is still supplied from the South Wales Power Co. The Tylorstown station commenced running in January last, and an uninterrupted supply has been maintained since that time.

A plan and elevations of the power station are given in Fig. 2, and Fig. 3 is a general view of its exterior. The building itself consists principally of a commodious engine-room, with a boiler-house parallel to it. The cooling towers are placed at one end, while the other end is free for extensions. The external appearance is that of a handsome red-brick building, much more artistic in its general features than many power stations, although without any unnecessary elaboration. The building is constructed on a steel frame, which sustains the whole weight of the roof and upper floors; the brickwork, therefore, merely serves to clothe the skeleton. This type of building was adopted on account of the ever-present possibility of subsidence at the surface of a colliery. The engine-room walls are faced with glazed brick, and the floor is finished with red tiles, which give a very pleasant effect. The north end of the building is temporary, in view of future extensions.

The boiler-house at present contains four water-tube boilers of the three-drum type, made by the Stirling Boiler Co., each having 6,209 sq. ft. of heating surface. Each boiler is provided with two underfeed mechanical stokers, and a superheater of the McPhail type with 800 sq. ft. heating surface, and is capable of evaporating 30,000 lb. of water per hour at a pressure of 180 lb. per sq. in., and imparting a superheat of 150° F. These boilers are arranged in two batteries, each battery being connected by a breeches piece to a steel chimney 7 ft. diameter and 75 ft. high. These chimneys are quite independent, and are not in any way connected by flues. Forced draught is supplied to the grates by a pair of Musgrave fans, each belt-driven by an electric motor.

The coal-conveying arrangements are of some interest. The coal used, which is "Ferndale Small," is run into Messrs. D. Davis and Sons' private siding from the Taff Vale Railway, and an ingenious arrangement of hydraulic rams is provided for tilting the wagons. This is supplied with water direct without the use of any accumulators from the boiler-feed pumps. This arrangement was practically complete at the time of our visit, but had not yet been taken into actual use. The coal is to be thus tilted into a hopper below the ground-level, from which it is carried by a motor-driven inclined band conveyor into and along the boiler-room, where, by means of a throw-off carriage, the coal is discharged in the usual way into the overhead bunkers in the boiler-house. These bunkers have a capacity of 150 tons, and the coal is carried by shoots at the bottom of the bunkers to the stoker hoppers. The conveyor is driven through suitable gearing by a continuous-current motor of about 7 B.H.P. situated at the extremity of the conveyor at the south or permanent end of the

Digitized by Google

boiler-house. As the inclined and elevated portions of the conveyor are, in plan, in the same straight line, and the supply hopper is at a little distance from the temporary end of the station, all that will be necessary when dealing with extensions to the boiler-house is to prolong the horizontal portion of the conveyor running over the bunkers, and make the angle of the inclined portion somewhat steeper. The capacity of the conveyor is 20 tons of small coal per hour, and consisting, as it does, of a band conveyor pure and simple, it runs with remarkably little noise. The ash from the stokers is removed by opening a sluice valve under the boilers, when the ash falls into narrow-gauge trucks in the boiler-room basement.

The water supply is obtained by pumping from the No. 8 pit, close by, and is stored in a large cast-iron tank outside the building. There is also storage in a large tank 100 ft. long under the boilers. The feed-pumps, of which there are three, are all steam-driven, and were supplied by Messrs. Clarke, Chapman & Co., of Gateshead. They are of this firm's tandem-compound type, and each is capable of delivering 5,000 gallons of water per hour against the boiler pressure. As already mentioned, they will also supply water to the rams of the coal-wagon tip. The steam supply to the feed-pumps is taken from a separate steam range connected to all the boilers on the boiler side of the superheater, so that they are fed with saturated and not superheated steam.

The exhaust steam from the pumps is taken to a Cochrane open-type exhaust steam heater, where it heats the feed-water on the suction side of the pumps. For use in emergency a Worthington tank pump is provided, which draws from the river in the unlikely event of water from the mine failing.

The feed-water is all passed through a recording water-meter on the Venturi principle of Messrs. George Kent and Co.'s make, the indicating portion of which is situated on the switchboard gallery. In this apparatus the quantity of water passing is measured by observing the difference of head at two points in a pipe where the diameters are different, and where, therefore, the velocity of the water is different. The difference of pressure is measured by means of a mercury U tube, in one arm of which is a float. This float carries a rack which communicates with an ingeniously arranged clockwork discontinuous integrating gear, by means of which a dial counter is propelled forward periodically by an amount corresponding to the position of the float; a direct reading pointer at the same time indicates the rate of flow of the water at any instant. Careful records are kept of the behaviour of the boiler furnaces as revealed by analysis of the flue gases by means of a " Sarco " CO_2 Recorder supplied by Messrs. Sanders, Rehders & Co. (see Electrical Engineering, Vol. II., p. 558), and the degree of superheat of the steam can be ascertained in the engine-room by reading of the dials of a series of Steinle steel-mercury thermometers.

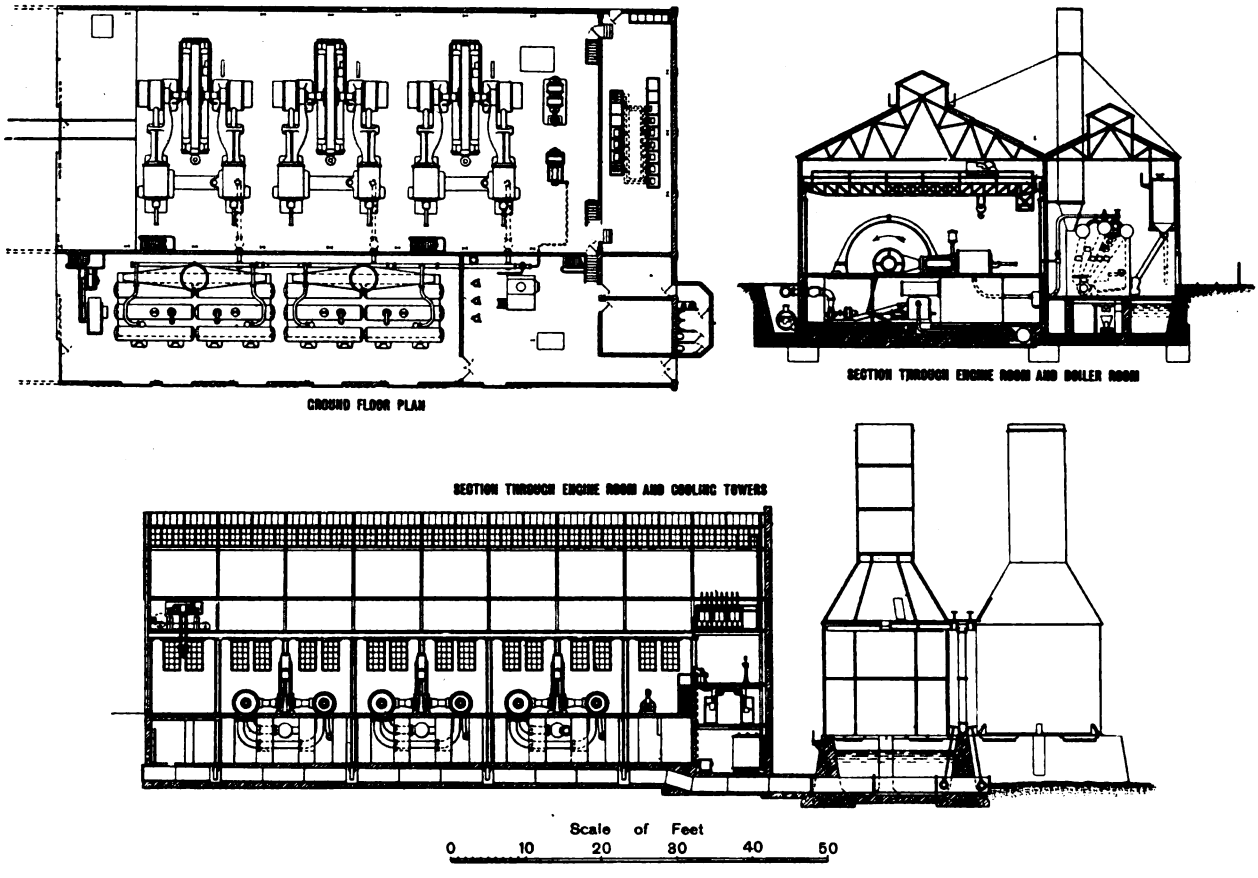

Fig. 2.—Plan and Sectional Elevations of Power Station.

A general view of the engine-room is given in Fig. 4. The three main generating sets, which form the instalment of plant already erected, consists of large slow-running revolving-field three-phase alternators each of 1,600 kw. capacity, and directly coupled to horizontal cross compound engines. These engines were manufactured by Messrs. Sulzer Brothers, of Winterthur, Switzerland, and are of their standard drop-valve type. Each engine is capable of giving 2,500 B.H.P. at normal load at a speed of 94 r.p.m. The diameter of the high-pressure cylinders is 33½ in., and of the low-pressure cylinder 56 in. diameter, with a stroke of 55 in. They are supplied with steam at a pressure of 170 lb. per sq. in., with a superheat of 150° F. at the stop valve. Each engine is provided with two jet condensers and feed heaters. The air pumps for these condensers are driven from the connecting rods of the engines, and with the condenser are situated in the basement directly below the engines. The feed heaters are very com-

Digitized by Google

pactly arranged above the condensers. The injection water is taken from cooling-tower concrete tanks through a 4 ft. diameter main buried in the engine basement floor, and after passing through the condensers is collected in the wrought-iron hot well main. The circulating water is lifted to the cooling towers by centrifugal pumps connected to the hot well. There are three natural draught circular steel cooling towers 33 ft. in diameter at the base and 83 ft. high. The circulating water enters at a level about 30 ft. from the base, and is discharged into wooden troughs, which evenly divide the water as it falls on cross timbers beneath, and so break it up into a fine rain. After cooling the water is collected in the concrete tanks under the towers.

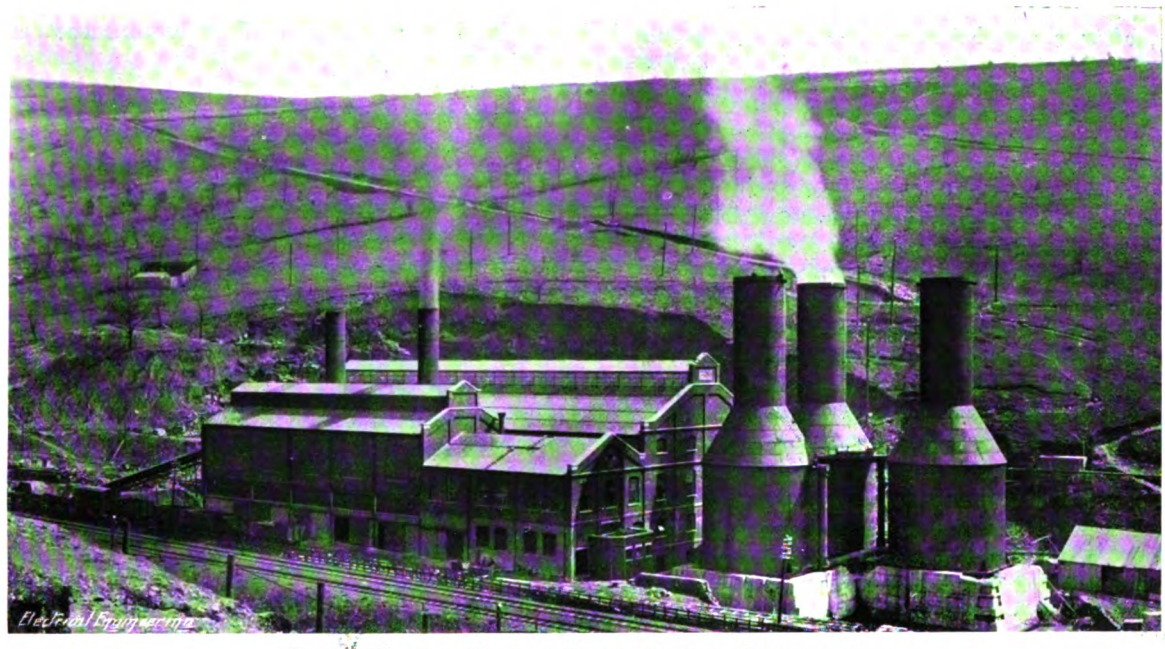

FIG. 3.—GENERAL VIEW OF POWER STATION, TYLORSTOWN.

The alternators, which, together with the whole of the electrical equipment, was supplied by the Lahmeyer Electrical Co., are, as already stated, coupled directly to the Sulzer engines. They are of the revolving fly-wheel type, and each has a normal continuous output

of 1,600 kw. at a power factor of 0·85 and a pressure of 2,200 volts three-phase. They are further capable of overloads of 20 per cent. for two hours, or 30 per cent. for half-an-hour. The temperature rise was guaranteed not to exceed 45° C., as measured by thermometer, after a ten hours at full load. The total

battery can also be charged by the Bellis set, the generator of which is so arranged that its voltage can be increased to 290 volts in order to allow of its acting as a spare in case of a breakdown in the motor-generator set.

This battery is left floating on the excitation

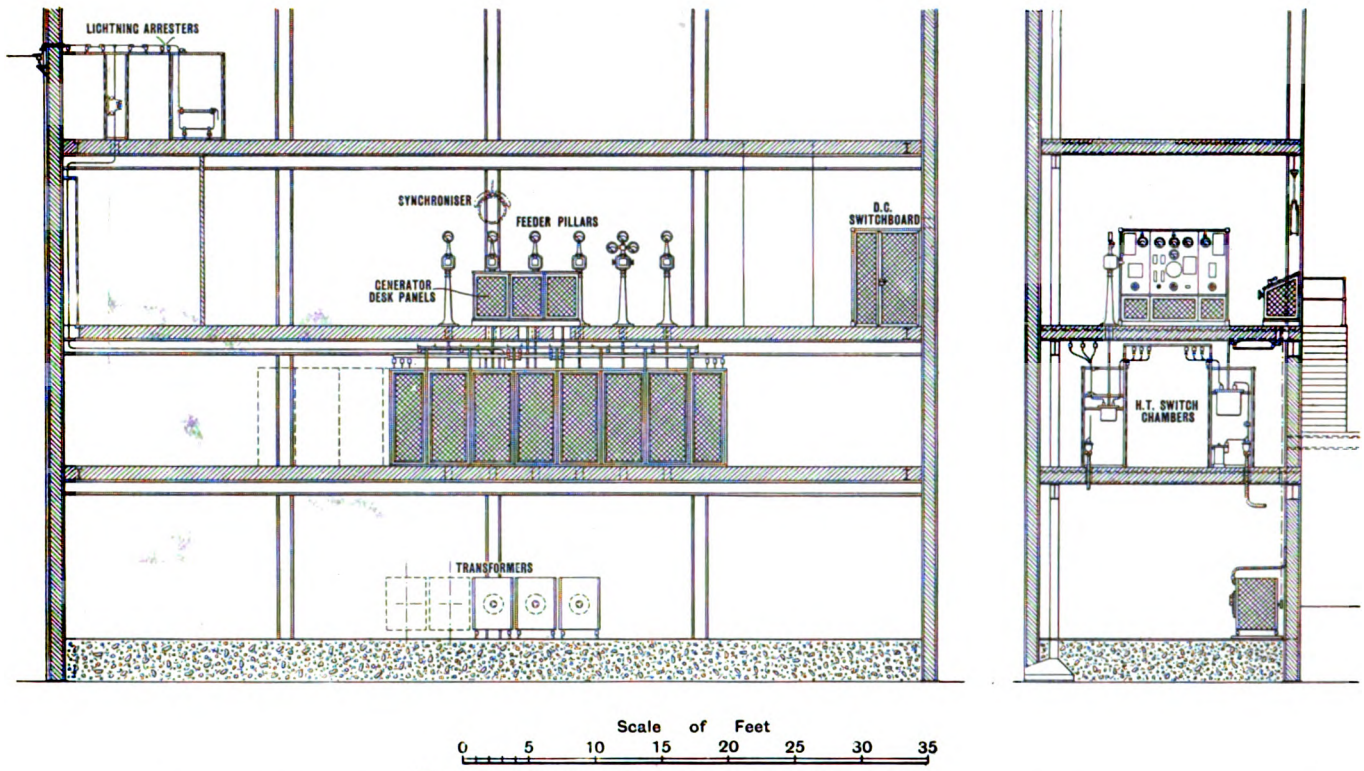

Fig. 5.—General Arrangement of Switchgear.

Note.—Since the drawing from which this illustration is reproduced was made, certain modifications have been effected in the arrangement. For example, the D.C. switchboard has been placed at the other end of the gallery and the order of the feeder pillars rearranged.

weight of each generator is 107 tons; of the revolving field approximately 75 tons.

The generators are separately excited at 200 volts from a 75 kw. Bellis-Lahmeyer steam-driven exciter, running at a speed of 525 r.p.m. As spare to the steam exciter there is a 100/120 kw. motor generator booster set, consisting of a 180 B.H.P. 2,200-volt three-phase

bus-bars, which are also used for station lighting, for driving a certain number of the auxiliary motors in the station as well as for the tripping circuits of the automatic switchgear. The 7 B.H.P. coal hoist motor, which might be required to be used when the alternating plant is shut down, is supplied from the continuous-current circuit. One of the forced draught fans

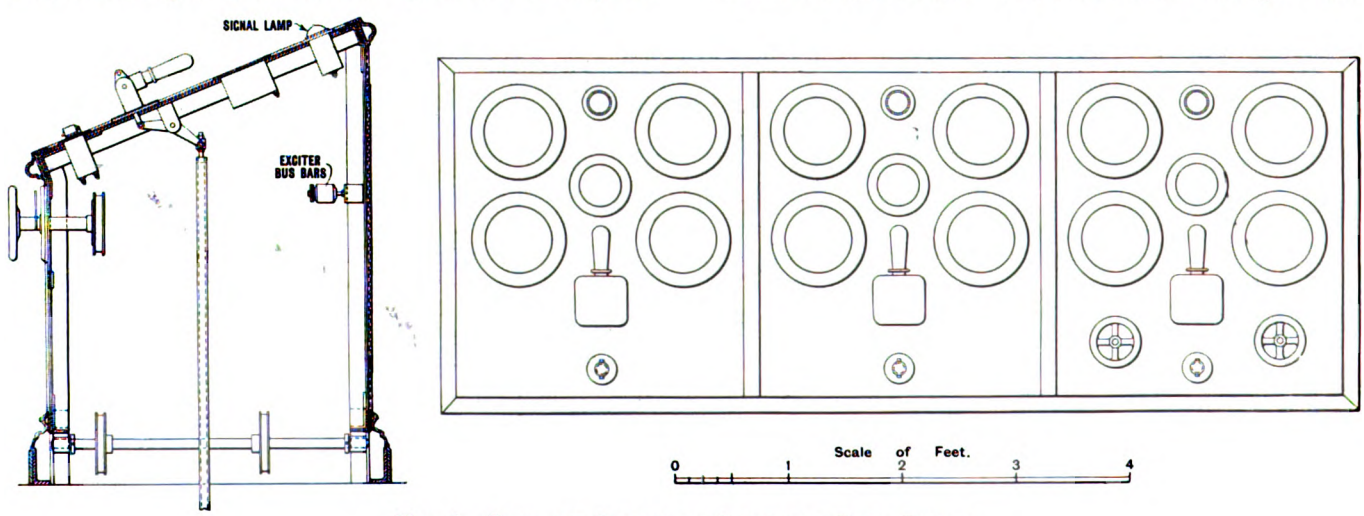

Fig. 6.—Plan and Section of Generator Desk Panels.

motor, coupled to a shunt-wound 120 kw. generator. The booster is mounted at the end of the shaft, and is capable of raising the voltage from 200 to 290 volts to charge the station battery; the latter has a capacity of 380 ampere hours when discharging at a 38-ampere rate, and consists of 115 Tudor cells. The regulation is done by hand by a 21-contact regulating switch. The

is driven by a 20 B.H.P. continuous-current motor, but the other is coupled to a three-phase induction motor of the same power running direct off the 2,200-volt circuit. All the circulating pumps are driven by three-phase motors. The engine-room is spanned by an overhead travelling crane of Messrs. Herbert Morris & Bastert's manufacture, constructed for dealing with 25

Digitized by Google

tons. The span is 67 ft., and the hoisting speed, when fully loaded, is 12 ft. per minute. The crab traverses at 80 ft. per minute, and the crane travel speed is 130 ft. per minute.

The electric current is taken from the generators to the main switchboard, which is situated at the south end of the building, and presents a number of interesting features. A general idea of its arrangement can be obtained from Fig. 5, which shows the disposition of the apparatus on the four floors. In the basement are placed the field rheostats, worked by chains from the operating gallery, and also the main step-up transformers for the extra high-tension transmission lines. Above this, slightly below the engine-room floor, is the high-tension switch-room, over which is the switchboard gallery proper, containing a board of the desk pattern, from which the generator circuits are controlled, and a series of switch-pillars for the feeders. These desks and pillars merely carry switch-handles and low-tension instruments. The actual switches themselves are in the high-tension chamber below. This has the advantage of giving ample room for the disposition of the high-tension gear in a chamber which need only be visited for the purposes of inspection, and leaves the switchboard operators free to attend to their duties on the platform. The arrangement may be said to be even safer than a switchboard of an ordinary low-tension station. The switchboard for the exciter and continuous-current auxiliary circuits is at the end of the operating gallery. The top floor is devoted to high-tension apparatus, including lightning arrestors, &c., in connection with the outgoing aërial lines.

Details of the three Lahmeyer desk-boards which form the generator panels is given in Fig. 6. The lever handle which controls the oil switch below through a system of rods is placed in the centre of the sloping top of the desk, and is surrounded by round-pattern instruments sunk flush with the board. The hand-wheels controlling the rheostat switches in the basement are mounted on the vertical front panels. The instruments on each generator panel, all of which are worked by current or potential transformers in the high-tension chamber, comprise an ammeter, machine voltmeter, exciter ammeter, and synchronism voltmeter. Indicating lamps showing whether the oil switches are "on" or "off" are also provided, and these are sunk into the instrument panels. A rotary lamp synchroniser is placed in full view of the operator at the desks, suspended from the upper gallery. The generator oil switches are fitted with automatic releases actuated by Ferranti maximum and reverse current time-limit relays. The excitation bus-bars are carried through the interior of the desks, but the field circuits are made and broken by a special switch provided with carbon contacts and discharge resistance attached to the rheostats in the basement and actuated mechanically when the last contact is reached.

One of the feeder pillars is shown in Fig. 7. They are mounted directly above the feeder oil switches, and carry the switch handle and feeder ammeters. The feeder oil switches are provided with overload relays only. Starting from the right-hand side, the first two pillars relate to the duplicate feeders leading to Nos. 8 and 9 pits. Duplicate feeders are also provided to Nos. 6 and 7 pits, but only one pillar is provided for these, as the change-over is effected by links in the basement with porcelain handles, which can be withdrawn and replaced after the manner of switch fuses. Another panel, provided with a set of three voltmeters for leakage detection, is connected to the 2,200-volt station circuit, on which the auxiliary motors, &c., are run. The remaining three-feeder pillars are for the circuits to the step-up transformers in the basement, which feed the 6,600-volt transmission lines to the more distant groups of pits. The secondaries of these transformers are connected direct to the lines without further switches. There are at present installed three three-phase transformers, each of a capacity of 500 k.v.a., but one of these is about to be replaced by a 1,000 k.v.a. transformer.

The arrangement of the switchgear in the high-tension chamber is very straightforward. The apparatus is not contained in brick or concrete cells, as is sometimes the case, but is mounted on an iron framing divided into sections enclosed in perforated metal sides, each directly under and relating to its own panel. Thus the generator gear is on one side of the room, and the feeder gear on the other. The bus-bars are at the top, and form a closed ring which can be sectionalised at a number of points by the removal of isolating links.

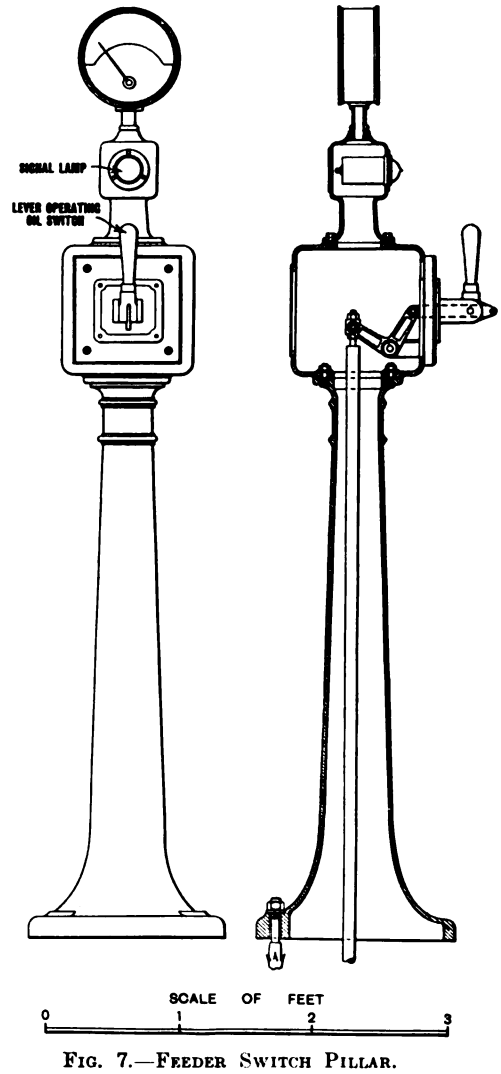

Fig. 7.—Feeder Switch Pillar.

The bus-bars are protected from the effects of abnormal voltage surges by spark gaps in series with glycerine resistances. The oil switches are mechanically operated from the control panels upstairs, and, as already stated, are fitted with tripping gear worked by the 200-volt continuous-current bars, and provided with Ferranti relays. These relays are placed in the high-tension switchroom on the outside of the cell to which they refer. The only circuit not provided with release gear is the station 2,200-volt circuit already mentioned, which is provided with a plain oil switch and the Lahmeyer type of high-tension oil-immersed spring break fuse. The distributing "board" for the station circuits is also in the high-tension room at the side.

The gear for the outgoing overhead lines on the top floor includes oil fuses for each line and the lightning protection apparatus, consisting of disc-shaped choking

Digitized by Google

coils and horn spark gaps with water resistances. No switches are provided, but there are disconnecting links by means of which any line can be isolated.

The continuous-current board in the operating gallery does not call for much remark. It is of white marble, and consists of two machine panels provided with automatic cut-out at each end for the steam and motor-driven exciters respectively, while the central part of the board serves as battery and distribution panel.

The current is taken from the power station by main feeders to distributing centres at the various pits. The motors are generally worked at 2,200 volts, but in certain places, in accordance with the Home Office Rules, the current has to be stepped down by transformers to 440 volts.

As already stated, duplicate 2,200-volt cables are taken to Nos. 8 and 9 pits, which are close to the generating station. Nos. 6 and 7 pits are about 900 yards from the power station, and current is taken to them at 2,200 volts by an overhead line. This does not start from the station itself, but from a lightning arrester house near the river. At the pit end this line terminates in a combined lightning arrester house and distributing station. The only other 2,200-volt overhead line in the scheme is that which is to be constructed up the side of the mountain to supply an electrically-driven rubbish tip.

In the case of Nos. 1 and 5 pits at Ferndale, which are 2,500 yards away, and Nos. 2 and 4 pits, which are some 2,000 yards further up the valley, the current is transmitted by a triplicate overhead line at 6,600 volts. This line is taken direct from the generating station in the first place to the distributing station, from which the supply to Nos. 1 and 5 pits and the adjoining workshops is given. This distributing station can be seen in Fig. 8. A 6,600-volt cable is also taken from this distributing station across the river and on a little way to a lightning arrester house, from which a further overhead 6,000-volt line is taken to another distributing station in the basement of the fan house at what is known as the middle fan pit. This line continues to another distributing station supplying Nos. 2 and 4 pits, the foundry, and fitting shops, and is taken further to the upper fan pit. The middle fan house distributing station is also connected by 440-volt cables to the electrically-driven shops, where the company construct their own railway wagons, and to Nos. 2 and 4 pits.

The overhead lines are carried on wooden poles entirely without cross-arms. The insulators are of the three-shed pattern, made all in one piece, and 3½ in.

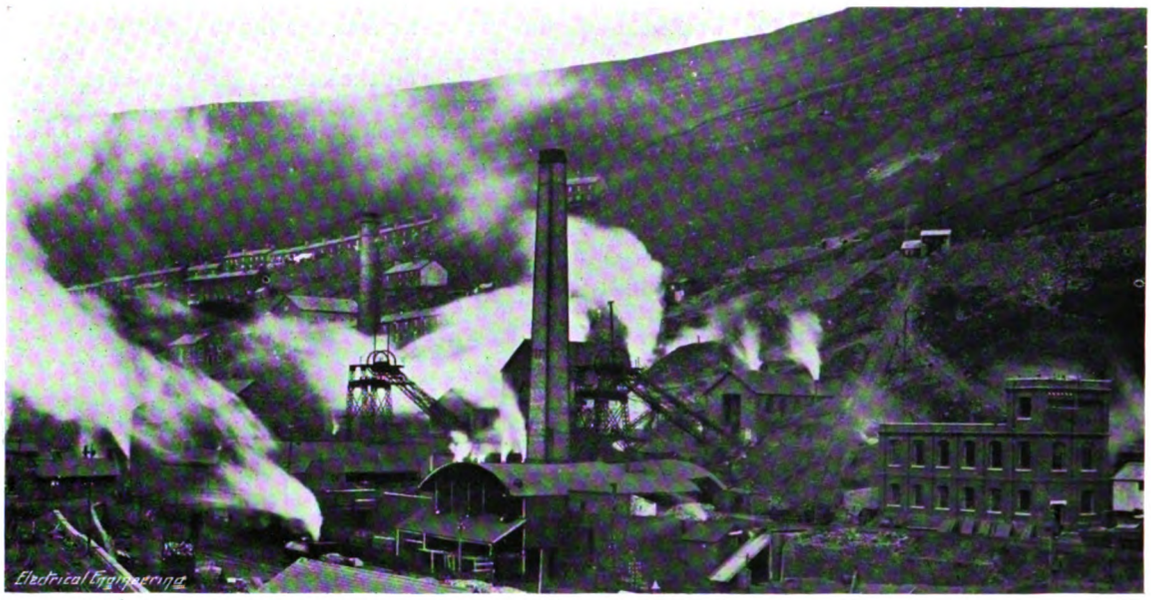

Fig. 8.—General View of Nos. 1 and 5 Pits, showing Distributing Station.

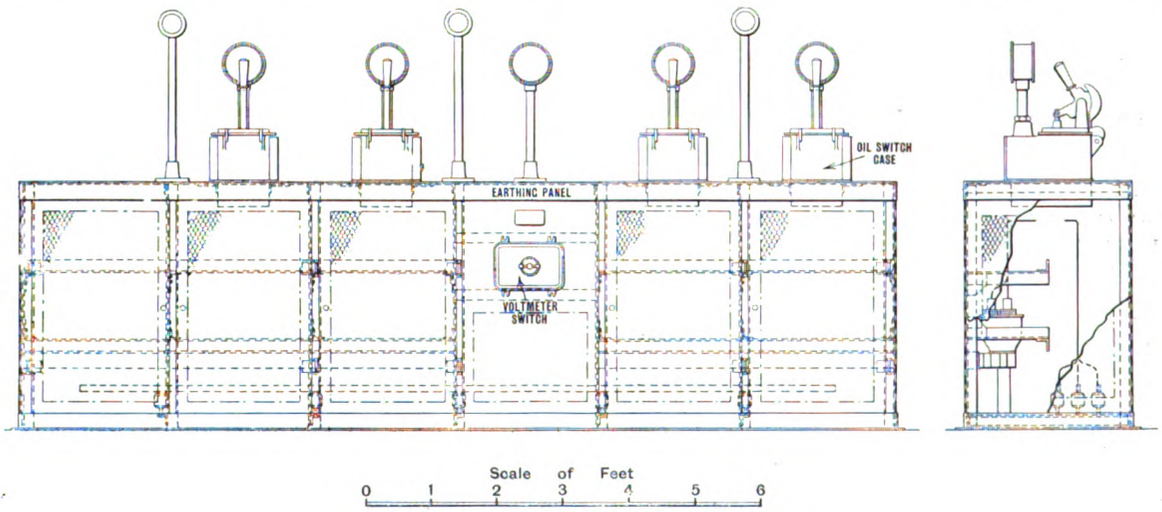

Fig. 9.—Distributing Board of Middle Fan Pit.

Digitized by Google

high overall. They are carried on malleable iron pins supported on short iron brackets affixed on alternate sides of the poles. All these brackets are connected to a galvanised-iron wire running helically round the pole and leading to an iron wire strung above the conductors and affixed to the tops of the poles and efficiently earthed at certain points.

The sub-stations are all similarly equipped, and only vary as regards their capacity and the arrangement of the apparatus in the particular buildings in which they are situated. They are usually combined with lightning-arrester houses, and in two cases form the basements of buildings, where electrically-driven ventilating fans are at work. It will suffice to indicate the general features of their equipment as it is unnecessary to describe each in detail. The transformers are principally of the Lahmeyer oil-immersed pattern, but some air-cooled Berry transformers supplied by the British Electric Transformer Co. are also used for the all the apparatus fully enclosed in cast-iron cases. The panels for the incoming feeders are similar to the branch circuit panels, and the bus-bars are taken horizontally along the back inside the cases; each distributing cable is also provided with an earthing panel for measuring the leakage on each phase. The oil switches are fitted with automatic overload releases, which can be set to any required overload by means of a key without opening the cases.

From these sub-stations cables of a special armoured mining type are taken down the pits; the vertical portions in the shaft are held by a special form of wood cleat, spaced at intervals of every ten yards. These are each 3 ft. in length in the direction of the cable; the backs are in one piece, but the fronts are in separate pieces, so that where there are several cables any one can be removed without disturbing the others. These cables lead to underground switch-rooms containing enclosed switchgear of an exactly similar type

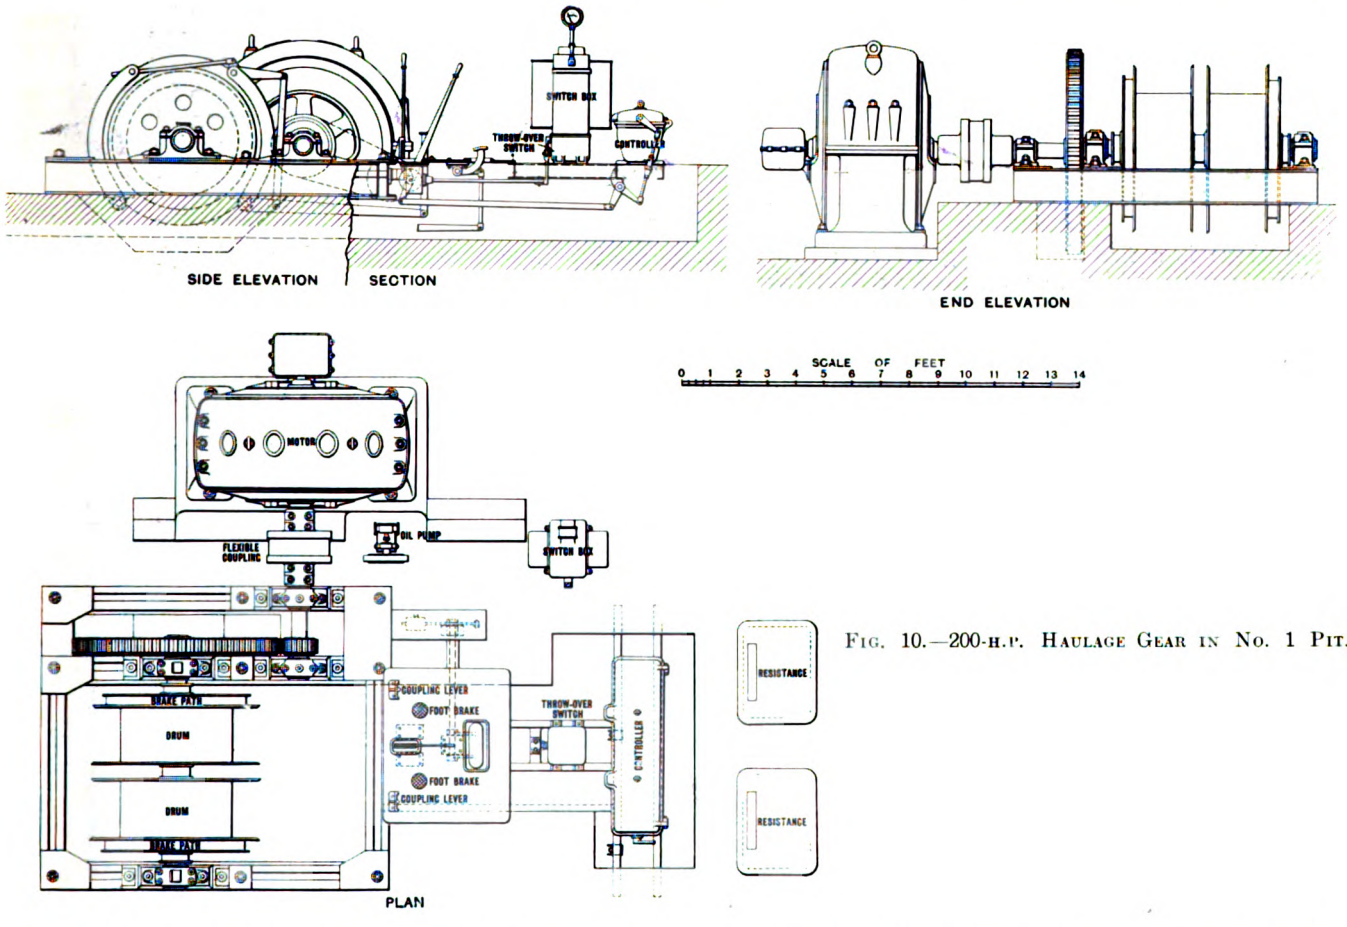

Fig. 10.—200-h.p. Haulage Gear in No. 1 Pit.

440-volt circuits. The lightning arrester arrangements have already been referred to, and each line entering a sub-station can be isolated by a disconnecting link.

The surface lighting at 220 volts at the pits is mostly supplied by continuous current from motor-generators. There is, for example, in the distributing station forming the basement of the fan house at No. 9 pit, a motor-generator consisting of a 2,200-volt induction motor driving a continuous-current generator, but an alternative supply is provided for in the event of breakdown of this set by means of a spare generator, which can be belt-driven from one of the large three-phase motors driving the fan.

The most interesting feature, however, of the sub-stations is the switchgear, which is of a special enclosed type developed by the Lahmeyer Co. for mining work. Details of the arrangement of a typical distribution board are shown in Fig. 9, which represents part of the gear used at the middle fan pit. The gear in all cases built up of a number of similar units, with to that in the sub-stations on the surface already described. The method of taking cables along the walls of the galleries underground is of some interest. They are sunk in the walls on timber shelves let into the wall, and covered by a wooden cover. The cables are thus well protected, but extremely accessible.

One of the most important of the various ways in which electric power is utilised in the Ferndale Collieries is for underground haulage. Some twenty-two of these electric haulage gears are being installed, varying in size from 200 h.p. to 50 h.p. The gears were made specially heavy to Mr. W. H. Patchell's specification by the Uskside Engineering Co. Slow-speed motors have generally been adopted, and the electrical equipment is of massive construction, supplied by the Lahmeyer Co. The controllers are of a new design arranged by the Consulting Engineer, in which special attention has been paid to obviating any possibility of the troubles which have arisen in some other cases through burning of the contacts. These

Digitized by Google

haulage gears are illustrated in Figs. 10 and 11. They are generally of main and tail type, and work at a speed of six miles an hour. They are principally driven through single-reduction gearing, but in some cases, to suit the exigencies of the positions in which they had to be installed, double-reduction gearing was chosen. In all cases there is a flexible coupling between the motor and the gearing, which to a very large extent takes the jar of the gear off the motor. The motors are of the slip-ring induction pattern with enclosed slip-rings. We are informed that these electrically-driven gears are very popular with the drivers; and, owing to their reliability and ease of working, not only have great economies been effected over the old steam-driven haulage gears, but it has also been possible to obtain a greatly increased output, as there are no delays in starting up, for the haulage gear commences work immediately the driver manipulates the lever. A considerable proportion of these electrical haulage gears had been in operation for some time before the completion of the Tylorstown power station, on the mains of the South Wales Power Company.

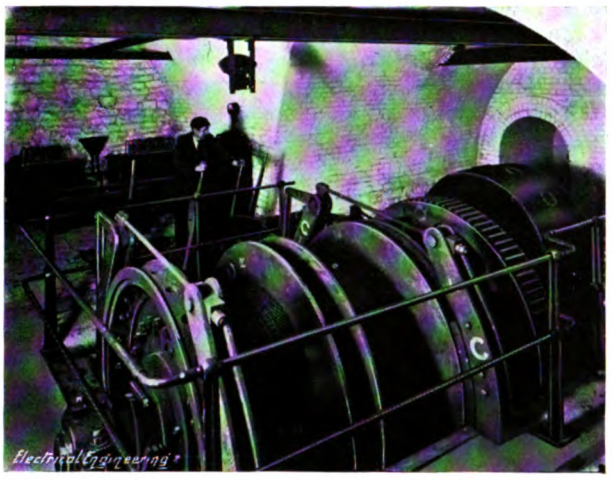

Fig. 11.—200 h.p. Underground Haulage Gear.

Pumping in these mines is not such a serious matter as in many collieries, as the amount of water in the pits is not excessive. Practically the whole of the underground pumping is now being handled electrically, in some cases by three-throw pumps made by the Uskside Co. and in other cases by high-lift Sulzer centrifugal pumps.

The conversion of the ventilating plant to electrical driving is now nearly complete. This is a most important part of the work, not only from the Colliery Manager's point of view, but also inasmuch as the continuous use makes it a most desirable load for the power station.

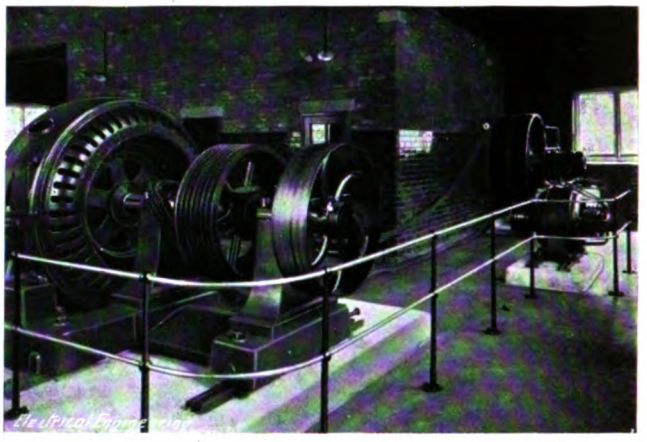

Fig. 12.—One of the Motors driving Sirrocco Fan at No. 9. Pit.

The positions of the principal fans are shown in the plan in Fig. 1. At No. 9 pit a "Sirocco" fan has been put down to handle 300,000 cubic feet of air per minute at a 4-inch water gauge. This fan is driven electrically from either end of its shaft by two Lahmeyer motors working at 2,200 volts. One of these motors is shown in Fig. 12. This fan runs continuously day and night except for a period of about half-an-hour once a week for cleaning. One of the "Schiele" fans at No. 6 pit, which have been driven for several years by a steam engine and doing 300,000 cubic feet of air per minute at 3·5-inch water gauge, has lately been con-

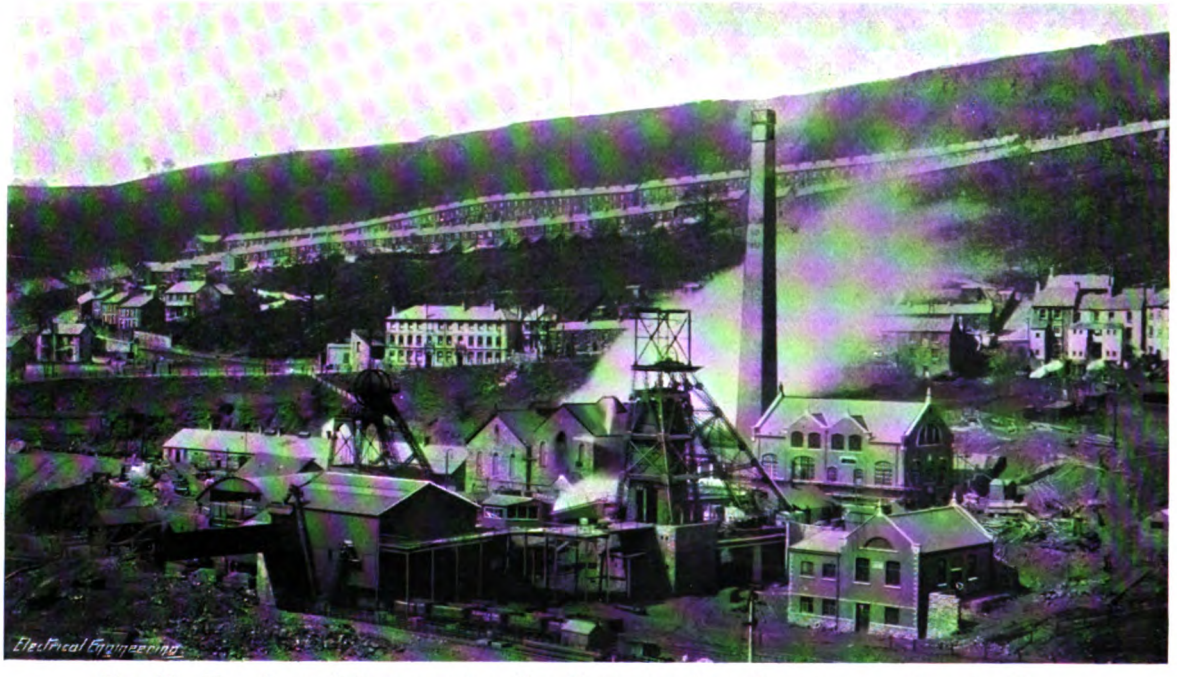

Fig. 13.—Nos. 8 and 9 Pits, showing Fan House and New Building for Electric Winder.

Digitized by Google

verted to an electrical drive. Two further "Sirocco" fans are at present being installed, each capable of doing 125,000 cubic feet of air per minute at 4-inch water gauge. These are to take the place of steam-driven Waddle fans, which have been at work for over thirty years.

Perhaps the most interesting part of the installation is the main-shaft electric winder, which is being erected at the No. 9 pit. This will work on the "Ilgner" system, in which the excessive demands for power required for starting are met by a flywheel converter, and the control of the main continuous-current winding motors is effected by regulating the excitation of the flywheel generator. The electrical equipment is being supplied by the Lahmeyer Electrical Co., and is of a similar nature to that of the winder at the Matthias Stinnes mine at Carnap, in Westphalia, described in Electrical Engineering, Vol. II., page 605, and other well-known examples of main-shaft winding machines supplied by the firm. The machine differs, however, from the example mentioned in that a cylindrical drum is used instead of the Koepe pulley, which finds so much favour on the Continent. The installation is designed to raise 1,800 tons of coal per day from a depth of 570 yards. The actual winding drum and a portion of the mechanical gear was supplied by Messrs. Fraser & Chalmers. The winding of the shaft is being done at present by a temporary steam winding engine, which will be removed when the new electric winder is complete. The old and new winding engine-houses are shown in Fig. 13. We must defer a complete description of this interesting installation until its erection is in a more advanced stage.

Electrical power is employed for a number of purposes on the surface, including the driving of the screening plant, &c., wagon shops, and general workshops.

The Consulting Engineer, Mr. W. H. Patchell, M.Inst.C.E., of Caxton House, Westminster, has for many years been largely identified with the introduction of electricity for mines and was the Electrical Member of the Home Office Departmental Committee for the drafting of suitable rules for the use of electricity in mines. He has collaborated throughout with Mr. David Hannah, Manager to the Ferndale Collieries, to whom in a great measure credit for the success of the Ferndale installation is due. We wish to express our thanks to both of these gentlemen for giving us particulars of the installation and putting at our disposal the drawings and photographs from which the illustrations in this article were prepared. We should also like to acknowledge the facilities for inspecting the plant accorded to our representative by Mr. F. Llewellen Jacob, sub-agent to the collieries, and Mr. C. Kemp, engineer in charge of the power station.

HOLLOW REINFORCED CONCRETE POLES.

For Tramways and Overhead Distribution Lines

A NEW process for manufacturing hollow poles and pipes of reinforced concrete has just been introduced into this country by Messrs. Siegwart, Ltd., of 1 Great Chapel Street, Westminster. It is the invention of Mr. Hans Siegwart, of Lucerne, Switzerland, who is well-known as the inventor of a system of reinforced concrete fire-resisting floor construction made up of hollow tubular beams laid side by side. Fig. 1 gives the general arrangement of the machine for manufacturing Siegwart poles and pipes, as it has been erected at the works of Messrs. W. Cubitt & Co. at 260 Gray's Inn Road, London, W.C. This view shows the machine in an open concrete pit, with a track on either side, upon which trestles can be run, and a stage over the machine carrying a concrete mixer which

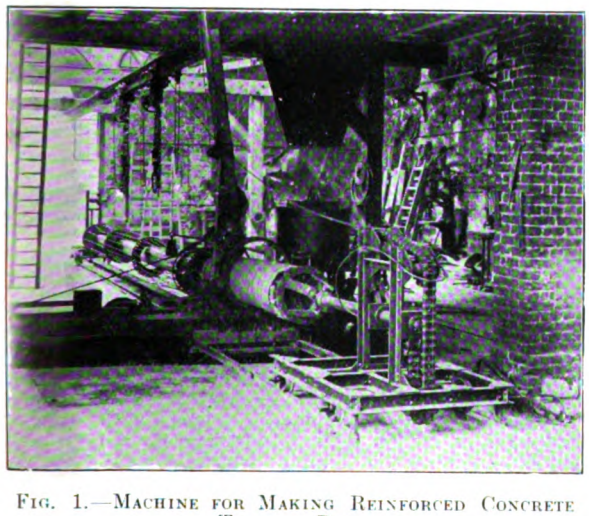

Fig. 1.—Machine for Making Reinforced Concrete Tubular Pole.

discharges into a receptacle below on the machine itself. The concrete used in the manufacture of poles and pipes is made of clean screened Thames grit, which mostly consists of sand, with occasionally small stones not larger than ½ in. maximum diameter, proportioned 3 to 1 of Portland cement. The concrete is mixed very dry, so that it only feels moist to the hand, and does not even stick together when pressed in the hand. It coheres in the manufacture by reason of the great pressure which is applied to it. The concrete, discharged from the mixer into the hopper, falls from the latter into a sheet metal drum. This drum holds about eight cubic feet, which is sufficient, as a rule, to make one pole or pipe. The hollow space in the interior of the poles or pipes is formed by means of the core of sheet iron, which is removed after the concrete has been applied to it. Gauge rings are arranged on the core at suitable distances from each other, and steel rods or wires of small section are passed through holes in these gauge rings, and arranged to lie longitudinally upon it. In the pipes these wires or rods are not stretched, for the operation of applying the concrete draws them taut, but in the poles the wires are stretched. Upon the track two trestles are placed, as shown in

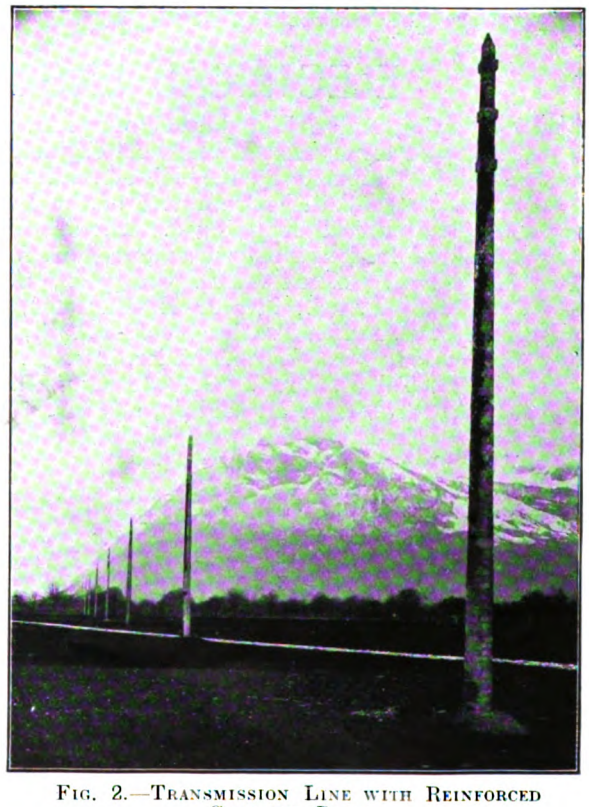

Fig. 2.—Transmission Line with Reinforced Concrete Poles.

Fig. 1, and the core is mounted between them so as to be capable of rotation. The trestles have toothed pinion wheels, which engage with a rack on the track, and are drawn gradually along in the direction of the machine. The concrete from the drum falls down a shoot upon a conveyer band or belt made of strong steel wire tightly plaited, which takes one wrap round the core, and is given its motion by passing over two wheels.

Digitized by Google

By means of the two heavily weighted levers, the sliding carriage applies a pressure of about 5,000 lb. to the conveyer-belt, so that the concrete is wrapped upon the core under this pressure. A band of strong cloth webbing about 4 in. in width is laid on top of the belt. The concrete falls upon this webbing, and the webbing and the concrete are wrapped round the core in a continuous spiral. The edges of the webbing just overlap, so that the concrete layer and the webbing are continuous. The pressure on the conveyer-belt draws the longitudinal wire or rod reinforcements closer together. The guide rings holding the longitudinals in position are engaged by a wheel attachment, so that they slide along the rods as the core gradually passes towards and through the machine. Immediately the webbing and concrete issues beyond the conveyer-belt, wire or wires, as close together as may be desired, are fed from a spool. The webbing is drawn up over a bar above this spool of wire, so that the wires for the spiral binding may be fed upon and into the concrete. The rotation of the core draws the wire or wires from the spool so hard against the layer of concrete that they penetrate into it for some distance. The rotating core draws the band of webbing upon the surface of the concrete again, and a pressure roller on the end of a long spindle, which is screwed forward by hand, works on a sheet iron ring, and presses this webbing and the concrete hard against the core. The finished pole thus consists of a concrete pipe with a wall thickness of from one to two inches, with a reinforcement consisting of longitudinal rods tied together by a wire wound on spirally.

The electric motor that works the machine is mounted on the bottom frame, and the driving is by means of a worm wheel and several chain wheels. The machine can be adjusted to the necessary angle to the core if this is tapered. As soon as the core has been drawn through the machine completely wrapped with the spiral binding, it is picked up by a travelling crane overhead and slung on one side to enable the concrete to harden and mature. To ensure it gaining maximum hardness it is constantly wetted. The interior sheet metal core can be removed by being reduced in diameter by the screw attachment after about 12 hours, and the webbing may be removed after six days hardening. To complete a pole, all that requires to be done after it comes from the machine is merely to fix a stopper in the top and make a square necking or blocking for fixing the cross-arms that carry the insulators. The former is cast in a mould and dropped into the top of the post; the latter is moulded by hand. When a more finished appearance is required, the poles are given a wash of cement grout or rendering of cement and sand, the latter giving a stone-like appearance, and, if desired, neckings or mouldings may be run round the pole and any other ornamentation done by hand.

Reinforced concrete poles constructed in this manner are very suitable for use on tramways and also on power distribution lines. The makers give the following comparative estimates of first cost and 50 years' maintenance for reinforced concrete and other poles.

Tramway Poles, Height 29ft.

	Siegwart £ s. d.	Iron. £ s. d.	Wooden (impregnated.) £ s. d.
Price of pole	3 0 0	6 10 0	14 5
Erection	1 0 0	1 0 0	9 7
Painting or renewal ...	—	2 11 0	9 8 4
Total cost in 50 years..	£4 0 0	£10 1 0	£10 12 4

Poles for Power Distribution, Height 36ft. 6in.

	Siegwart. £ s. d.	Iron. £ s. d.	Wooden (impregnated) £ s. d.
Price of pole	4 0 0	9 0 0	19 3
Erection	1 4 0	2 0 0	9 7
Painting or renewal ...	—	2 11 6	12 5 0
Total cost in 50 years..	£5 4 0	£13 11 6	£13 13 10

Fig. 2 shows a line of Siegwart poles that has been erected in the country, where no special finish is required. This view, therefore, shows the poles just as they come from the machine, with the markings upon them left by the webbing. A type of pole which has been erected at Miggern, Switzerland, has a total height of 54 ft. above the ground. As this height is greater than the standard length of poles manufactured, it has been obtained by fixing an ordinary pole in a base which stands 16 ft. 5 in. above the ground, and embedded 6 ft. 6 in. in the ground, resting upon a foundation of rough stones and filled with stones to form a bearing for the pole proper.

The number of persons in the gang of men that have been employed to work the machine described above in the experimental stages has been eight, but eventually only seven men will be required. One labourer is engaged feeding the mixer for the concrete; two labourers and a foreman are engaged working the machine; two lads are engaged in placing the reinforcements on the core, and one man is required to remove the poles. Only one skilled man is thus required. The capacity of the machine is, roughly, about one pole an hour, though with smaller poles and pipes the time required is slightly less. The concrete, of course, is not a big item, and the metal is also of small amount, and costs very little.

ELECTRICAL ENGINEERING NOMENCLATURE

THE following is the first portion of a series of definitions of terms used in electrical engineering which have been prepared by the sub-Committee on Nomenclature of the British Committee of the International Electrotechnical Commission. The sub-Committee consists of the following gentlemen:—Mr. A. P. Trotter (chairman), Colonel R. E. Crompton, C.B., Mr. W. Duddell, F.R.S., Mr. J. E. Edgcome, Sir John Gavey, C.B., Dr. R. T. Glazebrook, F.R.S., Mr. Robert Hammond, Mr. H. W. Miller, Mr. F. H. Nalder, Mr. H. Talbot, Mr. L. G. Tate, Prof. S. P. Thompson, F.R.S., Mr. A. H. Walton, and Mr. C. H. Wordingham. Words printed in capitals in the definitions are themselves defined elsewhere.

Accumulator: An electric cell consisting of plates or of grids in an electrolyte, of such a character that the electrical energy supplied to it is converted into chemical energy (a process called "charging"). The chemical energy can be reconverted into electrical energy (a process called "discharging"). Sometimes called a Storage Cell or a Secondary Cell. Several accumulators connected together in one circuit are sometimes called a Secondary Battery.

Alternator: A machine for generating alternating current. The exciting current is generally supplied by a separate machine called an Exciter. (The word "dynamo" should be reserved for a continuous current generator.)

Alternating Current: An electric current which alternately reverses its direction around a circuit in a periodic manner. The time occupied by each pair of half waves is called a Period. Abbreviated "A.C."

Ammeter or Ampere Meter: An instrument which indicates directly, in amperes, the value of an electric current.

Ampere: The current which is produced by the electrical pressure of one volt applied to a conductor, the resistance of which is one ohm. The Practical unit of electric current. It is one-tenth of the centimetre-gramme-second (C.G.S.) unit.

Ampere-Hour: One ampere flowing for one hour, or its equivalent; such as 4 amperes flowing for 15 minutes, &c.

Ampere-Turn: A practical unit of magnetomotive force. The number of turns or windings of a coil multiplied by the current in amperes which flows through it.

Annunciator: An apparatus containing a series of signals for indicating which of several circuits is making the call.

Anode: (*a*) In an electrolytic cell, the conductor through the surface of which the current enters the liquid. (*b*) In a primary cell, the metal (usually zinc) through which the current enters the electrolyte. (*c*) The terminal by which the current enters a cell or other apparatus, such as a vacuum tube, &c.

Aperiodic: The motion of the moving part of a mechanism is said to be "aperiodic" when it does not overshoot the mark on taking up a new position. Must not be confused with "dead-beat." See also Damped.

Arc: A discharge, continuous or alternating, of electricity through a gas in which the material of one or both the electrodes is volatilised, and takes part in the conduction of the current accompanied by a brilliant light.

Armature: (Originally the pole pieces attached to a lodestone.) (*a*) Of a permanent magnet. An iron bar for completing the magnetic circuit; sometimes called a Keeper. (*b*) Of a simple electromagnetic mechanism. The iron part of the magnetic circuit which is not covered with wire; it is generally set in motion by an electromagnet. (*c*) Of a generator. That part of the machine which is acted upon inductively by the magnetic flux; and from which the induced current is transmitted to the terminals. (*d*) Of a motor. That part of the machine which receives the current, and is acted upon inductively by the magnetic flux. In continuous current machinery it usually rotates, in alternating current machinery it is sometimes stationary. See Stator and Rotor.

Armouring: Of a cable. A protective metallic covering of wires or tapes, usually of iron or steel (verb: to armour).

Arrester: An abbreviation. See Lightning Arrester.

Astatic: A system of magnets or coils is said to be astatic when the polarities of its parts are so adjusted that the polarity of the whole is zero, and no directive effect is exerted on the system of a uniform magnetic field.

Asynchronous: A term applied to an alternating current generator or motor, the speed of which has no fixed relation to the frequency of the current.

Auto-Transformer: A transformer in which part of the winding is common to both the primary and the secondary circuits; sometimes called a Compensator.

Digitized by Google

Balancer: A dynamo, pair of dynamos, motor generator, or rotary converter, arranged to maintain the equality of pressure on the two sides of a three-wire system.

Bank: A number of similar pieces of apparatus grouped and connected to act together is sometimes called a bank. Thus lamps are banked in parallel, or in series, to form a resistance; and several transformers are banked to act as a single transformer.

Barretter: An instrument in which the current to be measured, generally alternating, flows through and heats a fine wire strip or filament, and causes a change in its resistance, which is taken as the measure of the current.

Battery: Two or more cells connected in one circuit.

Bifurcating Box: A box containing the joints between a two-core and two single core cables.

Blow (verb): When a fuse melts it is sometimes said to "blow," a term suggested, probably, from the result of the melting of a fusible plug in a steam boiler. The same expression is sometimes applied to the automatic opening of a circuit breaker.

Board of Trade: A British Government Department charged with the administration of, *inter alia*, the Electric Lighting and Power Acts, Railway and Tramway Acts, and of regulations made thereunder for the safety of the public, &c.

Board of Trade Unit: One Kilowatt-Hour. The expression "Unit" is officially used, and not the expression "Board of Trade Unit.

Bolometer: An instrument in which radiant energy to be measured causes an alteration of the resistance of a fine wire strip or filament.

Bond: (For tramway and railway rails.) A connector, usually of copper, used for electrically connecting the rails to each other or to a return conductor, in order to ensure good conductivity. (Verb: to bond.)

Boom: See Trolley Boom.

Booster: A dynamo, alternator, or transformer, interposed in a circuit for the purpose of increasing or decreasing the electromotive force acting in the circuit.

Braiding: A plaited covering of fibrous material or wire. (Verb: to braid.)

Branch Circuit: A circuit which derives its supply of current from points on another circuit.

B.T.U. or B.O.T.U.: See Board of Trade Unit. (Terms not recommended.)

British Thermal Unit: The quantity of heat required to raise a pound of water one degree from 60° F. to 61° F. Abbreviated "B.Th.U."

Brush: A conductor for collecting or delivering current from commutators or slip rings. Originally made of copper wires, afterwards of copper strips or gauze, or of carbon blocks.

Brush Discharge: A discharge having a feathery form and consisting of an intermittent partial discharge which takes place from a conductor when the potential difference exceeds a certain limit, but is not high enough to cause the formation of a true spark or arc. It is always accompanied by a hissing or crackling sound.

Brush Holder: The apparatus which holds the brushes.

Brush Rocker: The apparatus which enables the position of all the brushes carried by it to be altered simultaneously in either direction.

Buckling: Of accumulator plates. The distortion caused by uneven expansion.

Busy-Back: An electrical signal transmitted from one telephone exchange to another to indicate that the line wanted is in use.

Bus-Bar: Abbreviation for Omnibus-Bar. Conductors (generally on a switchboard and of comparatively large size) to which several mains or feeders are connected.

B.W.G.: Abbreviation for Birmingham Wire Gauge.

C.G.S.: Abbreviation for Centimetre-gramme-second.

Cable: For electrical purposes; a stranded conductor with or without protective covering.

Calibration: Of a measuring instrument. The determination of the value of the divisions of the scale of an instrument by comparison with a standard, or by some fresh determination.

Calorie: (*a*) The Calorie or Gramme-Calorie (also called the Small-Calorie) is the quantity of heat required to raise the temperature of one gramme of water one degree centigrade. (*b*) The Kilo-Calorie (also called the Great-Calorie) is one thousand calories, and is the quantity of heat required to raise the temperature of one kilogramme of water one degree centigrade.

Note.—The value of the calorie depends to some extent on the temperature at which the water is taken, and on the scale of the thermometer employed. The hydrogen thermometer is usually adopted as the standard, and the temperature selected is generally 15° C. or 20° C., or the mean 0° C.—100° C.

Candle Power: The luminous intensity, or illuminating power, of a source of light.

Candle Foot: See Foot Candle.

Capacity: (*a*) Of an accumulator. The quantity of electricity in ampere hours which may be taken from a cell at a given rate of discharge. (*b*) Of a Condenser. The quantity of electricity which must be imparted to a condenser, or to a conductor acting as a condenser, in order to raise its potential from zero to unity. (*c*) Of a Machine or of a Generating Station. This use of the word "capacity" is not recommended. The term Rating should be used.

Carcase: Of a dynamo, alternator, or motor. The assembled pole cores, pole pieces, and yoke or frame.

Cascade: (*a*) A series connection of two or more condensers. (*b*) A method of electrically connecting induction motors, whereby the induced part of one motor is connected electrically with the inducing part of the other. Also called Concatenation and Tandem.

Cathode: See Kathode.

Cell: (*a*) A source of electrical energy dependent on chemical action; complete in itself. (*b*) A compartment of a high pressure cellular switchboard. (*c*) A combustion chamber of a Dust or Refuse destructor.

Choking Coil: A coil with so great a self-induction that its impedence depends chiefly on the self-induction rather than upon the resistance.

Circuit: The conductors connected with a source of electrical supply are collectively called a circuit. When they form a closed path through which a current circulates there is a Closed Circuit. When the path is not closed and no current circulates there is an Open Circuit.

Circuit Breaker: A switch which is opened automatically when the current or the pressure exceeds (or falls below) a certain limit, or which can be "tripped" by hand.

Closed Circuit: See Circuit.

Coherer: (In wireless telegraphy.) A device employed at the receiving, and consisting essentially of an imperfect contact, or system of contacts, such that its resistance is altered on the reception of a signal.

Collecting Rail: See Conductor Rail.

Collector: A sliding piece which makes contact and collects the current from a fixed part of an electrical apparatus, or *vice versa*.

Collector Ring: A ring used for making a sliding connection between a fixed and a revolving part of an apparatus such as an alternator or a searchlight projector.

Commutator: An apparatus for reversing the direction of a current in any circuit. In a dynamo or motor that portion on which the brushes press and collect or deliver the current.

Compensator: See Auto-transformer.

Compound Wound: A generator or motor is said to be compound wound when the magnetic field is excited partly by series and partly by shunt coils, or independently excited coils.

Concatenation: See Cascade.

Concentric Cable: A cable consisting of two or more separate conductors arranged concentrically with insulation between them. Three conductors so arranged form a Triple Concentric Cable. The external conductor should be called "external," and not "outer," in order to avoid confusion with the outer conductors of a three-wire system.

Conductor Rail (Positive or Negative): A rail employed on electric railways for conducting current to or from the train. The terms Live Rail, Third Rail, Fourth Rail, Earth Rail, Collecting Rail, and Working Conductor are not recommended.

Conduit System: (*a*) For electric light and power distribution. A system of bare conductors carried on insulators in a conduit or culvert, generally of concrete. (*b*) For wiring. A system of metal or other pipes into which wires are drawn. (*c*) For traction. A system of bare conductors carried in a conduit, having an open slot through which a Plough makes contact between the conductor rails and the electrical equipment of the car. (*d*) For telegraphs and telephones. A group or collection of ways or passages called Ducts into which cables are drawn.

Consumers' Load Factor: The number obtained by dividing the actual consumption during a given period of time by what that consumption would have been had the maximum load reached during that period continued in use throughout the whole of that period.

Contactor: An electro-magnetic, electro-pneumatic, or automatic switch used for controlling heavy current circuits to motors, and which is itself controlled by a Master or Pilot Controller.

Continuous Current: An electric current in one direction and sensibly steady or free from pulsation. Abbreviated C.C. The term Direct Current is not recommended.

Controller: A compound or multiple switch containing the means for introducing resistances, or for connecting motors in series or in parallel. It has several steps or positions called Notches, and is intended for use on any notch for an appreciable period of time. It is to be distinguished, in this respect, from a Starting Switch. It is used for varying the speed or power of, as well as for starting, traction and other motors. A Master Controller, sometimes called a Pilot or Multiple Unit Controller, does not act directly on the current supplied to the motors, but works Contactors.

Converter: A revolving apparatus for converting alternating current into continuous current or *vice versa*; sometimes called a Rotary Converter. To be distinguished from a Transformer, Rectifier, or Motor Generator.

Core: (*a*) Of a magnetic circuit. That part which is within

Digitized by Google

the winding. The part outside the winding, if any, is called the YOKE. (*b*) Of a transformer. The whole of the iron forming the magnetic circuit. (*c*) Of a cable. The conductor with its insulation or dielectric. Two, three, or more cores may be laid together to form a TWIN, THREE-CORE, or MULTICORE cable. (*d*) Of an arc lamp carbon. The longitudinal filling.

COULOMB: The PRACTICAL unit of electrical quantity. One coulomb is equivalent to one ampere flowing for one second; 3,600 coulombs equal one ampere-hour. The term AMPERE-HOUR is almost universally adopted; the coulomb is seldom used.

CUT-OUT: A device for protecting apparatus from damage by overload. The term cut-out comprises all the separate parts which, together with their mountings and base, form the complete device, and the term includes FUSES and CIRCUIT-BREAKERS.

CYCLE: A term not recommended as a synonym for PERIOD. See PERIOD, ALTERNATING CURRENT.

DAMPED: The motion of a piece of mechanism is said to be damped when any oscillations which may be started rapidly die away. If no oscillations can be produced, it is said to be APERIODIC. See DEAD-BEAT.

DASH-POT: An appliance for preventing sudden or oscillatory motion of any portion of an apparatus by the friction of air or of a liquid.

DEAD-BEAT: An instrument or other mechanism is said to be dead-beat when the oscillatory movement rapidly dies away. To be distinguished from APERIODIC.

DERIVED UNITS: See PRACTICAL UNITS.

DIELECTRIC: Any material which offers high resistance to the passage of an electric current.

DISCRIMINATING CUT-OUT: A cut-out, usually on a switchboard, for interrupting the circuit when the normal direction of the flow of energy is reversed.

DISTRIBUTING BOARD: A board carrying small bus-bars, used for connecting a number of circuits to a pair of mains. Sometimes called a DISTRIBUTION BOARD.

DISTRIBUTING MAINS: The conductors which intervene between the feeders and the service lines, and which are collectively called "distributing network," or "low-pressure network," or the NET-WORK.

DIVERSITY FACTOR: The number obtained by dividing the actual output of any works during a given period of time by what that output would have been had the works operated throughout the whole of that period at the maximum load reached during that period.

DRAW-IN BOX: A box used in connection with a draw-in system of mains. When complete, it contains no links, fuses, or switches, but in some cases permanent joints.

DRAW-IN SYSTEM: A system of laying mains in which the cables or wires are drawn into pipes or DUCTS after the latter have been laid or fixed in position, in such a manner that the cables or wires can be withdrawn at any time without disturbing the pipes or ducts. Draw-in boxes, manholes, or junction-boxes are usually provided, through which the cables or wires may be drawn in or withdrawn.

DIELECTRIC: Any material which permanently offers high resistance to the passage of electric current.

DROP (IN PRESSURE): A difference of potential between any two points in a conductor through which a current is flowing, the conductor itself not being the seat of any electromotive force.

DROP SIGNAL: See ANNUNCIATOR.

DUCTS: Pipes or blocks perforated with holes through which cables are drawn. Usually non-metallic and set in concrete. The holes themselves are sometimes called ducts.

DYNAMO: A continuous-current GENERATOR.

DYNAMOMETER: (*a*) An instrument for measuring forces. (*b*) An apparatus for measuring the torque exerted by a prime mover or motor. (*c*) An instrument for measuring electric currents depending on the measurement of the electro-magnetic forces between two or more cells. (Abbreviation for ELECTRO-DYNAMOMETER.)

EAR: In overhead tramway work. A grooved metal fitting rivetted over, soldered or otherwise attached to, a trolley wire for the purpose of: (*a*) Supporting the wire. (*b*) Altering the horizontal direction of a trolley wire, termed a "PULL OFF." (*c*) Anchoring a trolley wire.

EARTH: (*a*) An electrical connection with the earth, intentional or unintentional, is called an EARTH. (*b*) (Verb: to earth.) To connect any conductor with the general mass of the earth in such a manner as will ensure at all times an immediate and safe discharge of electrical energy. Board of Trade definition of "efficiently connected with earth." (*c*) Earth circuit. A circuit of which the earth forms a part.

EARTHED CIRCUIT: A circuit, one pole of which is earthed at one or more points.

EARTH RAIL: See CONDUCTOR RAIL.

EFFECTIVE VOLTS: A term not recommended. See VIRTUAL VOLTS.

E.H.P.: Contraction for ELECTRICAL HORSE POWER.

ELECTRODE: A conductor by which an electric current passes into or out of an electrolyte or other substance.

ELECTRO-DYNAMOMETER: See DYNAMOMETER.

ELECTROLYSIS: The passage of an electric current through an electrolyte.

ELECTROLYTE: Any substance which undergoes chemical decomposition by the direct action of an electric current passing through it.

ELECTROCUTION: A form of capital punishment for criminals by electric shock.

ELECTROMOTIVE FORCE: That which causes or tends to cause an electric current. Abbreviated "E.M.F." See POTENTIAL PRESSURE, TENSION, VOLTAGE.

EXCITER: A dynamo used for exciting the field magnets of another machine. See ALTERNATOR.

FARAD: The PRACTICAL unit of electrical capacity. It is inconveniently large, and, therefore, capacities are usually reckoned in MICROFARADS.

FACTOR OF SAFETY: The ratio of the "ultimate breaking stress" to the "maximum normal working stress."

FAULT: Any local defect in the insulation or continuity of a conductor which interferes with its use.

FEEDERS: Conductors for conveying electrical energy from the place where generated or transformed to FEEDING POINTS or sub-stations. Not used for supplying consumers directly, owing to the varying pressure along their length.

FEEDER BOX or PILLAR: (For tramways or railways.) A box or pillar containing switches, links, and sometimes fuses for connecting sections of trolley wire or conductor rail with feeders. (For electric lighting and power.) A box containing links and sometimes fuses for connecting feeders with distributing networks.

FEEDING-POINT: The point or junction of a FEEDER with the NETWORK.

FIELD, ELECTROSTATIC: Any region in which there are electric lines of force, as in the space between a positively-charged surface and a negatively-charged surface.

FIELD, ELECTRO-MAGNETIC. See FIELD, MAGNETIC.

FIELD-MAGNET: Any magnet or electromagnet employed for the purpose of providing a magnetic field. (It is incorrect to speak of the field magnets of a dynamo or motor as its "fields"; they should be called its "magnets," if the term "field magnets" is too long.)

FIELD, MAGNETIC: Any region in which there are magnetic lines of force, as in the space between the poles of a magnet or within a magnetising coil. The intensity of the field is usually expressed in C.G.S. measure as the number of lines per square centimetre. One line per square centimetre is called a GAUSS. See LINE.

FIGURE OF MERIT: (*a*) Of a galvanometer. The deflection in millimetres per micro-ampere at a scale distance of one metre. (*b*) The current in amperes required to produce a deflection of one millimetre at a scale distance of one metre. Sometimes expressed as the number of megohms through which one volt will give that deflection. The complete period of a swing is taken at 20 seconds unless otherwise stated. (*c*) Of a telegraph instrument. The minimum current necessary to work the instrument with absolute certainty.

FLASHING: (*a*) Any process of manufacture involving the temporary electrical superheating of a glow lamp filament. (*b*) The coating of glow lamp filaments with a layer of carbon by heating them electrically in a hydrocarbon vapour.

FLASHING OVER: The temporary formation of an arc from brush to brush on a commutator.

FLASH TEST: The momentary application of a high electrical pressure between two conductors insulated from each other.

FOOT CANDLE: The illumination produced by one candle-power falling perpendicularly on a surface at a distance of one foot.

FOURTH RAIL: See CONDUCTOR RAIL.

FREQUENCY: The number of complete periods per second of an alternating current. Symbol . The term PERIODICITY is not recommended.

FROG: In tramway overhead work. A fitting uniting two diverging trolley wires with a single wire (*a*) provided with a spring tongue or (*b*) pull-over tongue, or (*c*) of the fixed type.

FUSE: The actual wire or strip of metal in a cut-out which may be fused by an excessive current.

GAUGE: (*a*) A general term applied to various kinds of measuring instruments and to linear measurements. (*b*) The thickness of a plate, or the diameter of a wire, on the inch, millimetre, or on any arbitrary scale. (*c*) The distance between the rails of a railway or of a tramway. In the case of a railway it is the distance between the inner sides of the heads of the rails. In the case of a tramway it is the distance between the inside edges of the tread of the rails, *i.e.*, over and including the grooves.

GAUSS: A name given to the absolute electromagnetic unit of magnetic induction in the C.G.S. system.

GENERATOR: Any machine capable of transforming mechanical into electrical energy, e.g., a dynamo or alternator.

GLOW LAMP: A term recommended instead of INCANDESCENT LAMP in order to avoid confusion with the "INCANDESCENT GAS" mantle.

GRAMME CALORIE: See CALORIE.

GREAT CALORIE: See CALORIE.

GRID: In an accumulator. The framework supporting the active material.

GROUND: A term used in America, having practically the same meaning as earth. See EARTH.

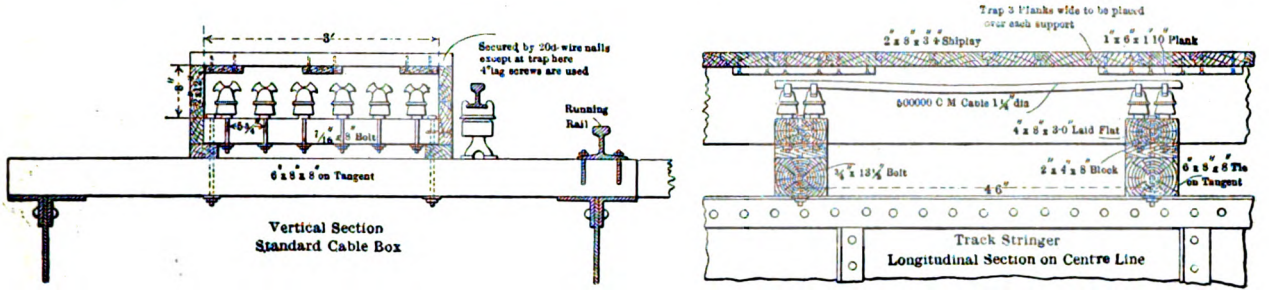
ELEVATED RAILWAY CONSTRUCTION IN AMERICA

Extensions to the Chicago South Side Elevated Railway

A DESCRIPTION was given recently in the *Street Railway Journal* of some extensions to the system of the Chicago South Side Elevated Railroad, including what is known as the Kenwood branch, which was opened last September, and the stockyards extension. The former line is partly earth embankment with retaining walls of a sufficient height to give 12 to 13 ft. clearance under the road bridges, but with a short length of steel structure at one end terminating in an overhead storage yard with a capacity for about 50 cars.

The stockyards branch, on the other hand, is entirely a steel structure. Because of the local difficulties, there are wide variations in the details of the structure, and hardly any two spans are alike. As nearly as possible, however, a standard form of deck plate girder construction was followed. The standard span on tangents is 40 ft., with double-column bents and short spans of 20 ft. over braced towers, put in between every fourth span, of greater dimensions. Each track is carried independently by two longitudinal girders stiffened with diagonal cross-bracing, top and bottom, and cross-frames in the centre of each span. The longitudinal girders are riveted to short cross-girders built on top of each column, and these cross-girders are connected together with angle ties and braces. Fig. 2 shows the details of a typical bent and longitudinal girder. A unique feature of the construction is the method of assembling the longitudinal girders so that they form a continuous bearing for the ties over the cross-girders of the bents. The longitudinal girders are notched out from 6 in. to 7 in. at each end just under the top flange angles, and are stiffened here by short pieces of angle iron riveted under the flange angles. The top flange of the cross-girder fits in this notch, and carries most of the load, a double row of rivets being provided, as usual, to secure the end stiffening angles of the longitudinals to the cross-girders.

Expansion joints are provided at approximately every 200 ft. The details of one of these are shown in Fig. 2. The longitudinal girders rest on brackets attached to the cross-girders, and are confined laterally, but are free to move longitudinally. These brackets are made up of two pieces of 15 in., 45 lb.



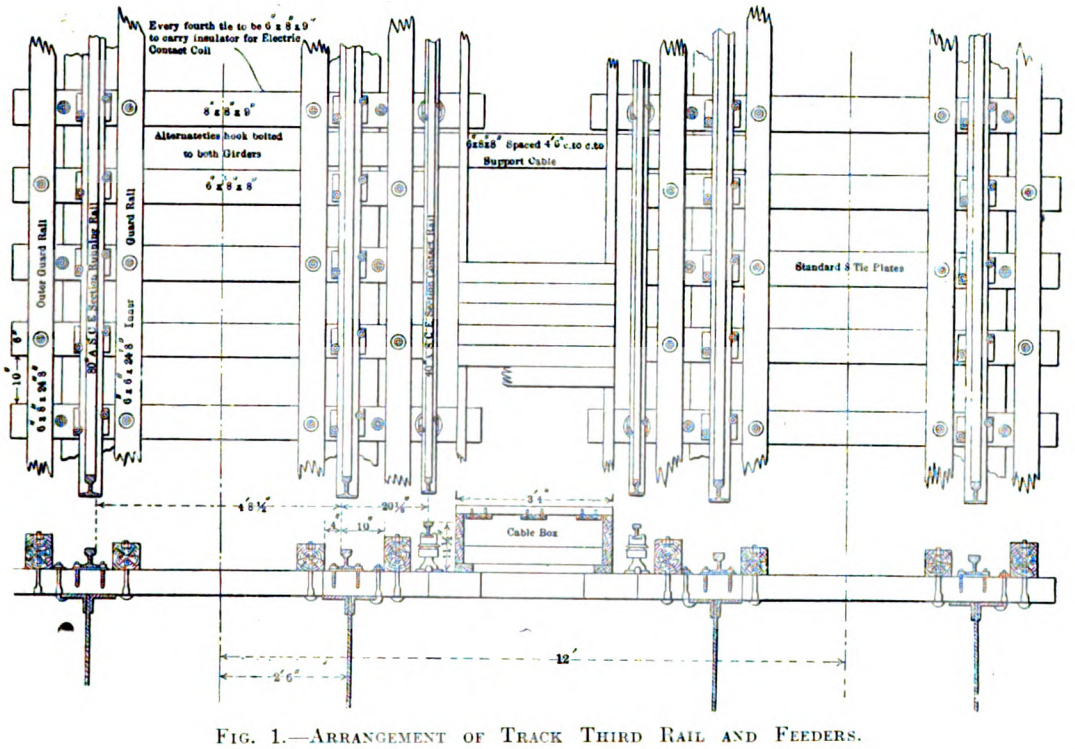


FIG. 1.—ARRANGEMENT OF TRACK THIRD RAIL AND FEEDERS.

The columns of the structure are made up of four Z bars, 3½ in. × 3½ in. × ⅜ in. × 6 in, and one ⅜-in. × 10-in. web-plate. The Z bars are continuous from the base plate up to the top flange of the cross-girder, but the narrow web-plate is carried up only to the springing line of the bracket angles, where it is butt jointed to the web-plate forming the cross-girders. The foundation base consists of a bed-plate, 26 in. × 26 in. × ⅞ in., two side-plates, 18 in. × 26 in. × ⅜ in., and corner angles, 6 in. × 6 in. × ¾ in. The two foundation bolts are carried up through the bed-plate, and are enclosed by crimped plates, ½ in. × 15 in. high, rivetted to the web of the column. The bolt-washers rest on the top edge of these plates.

The foundations for the structure varied according to local conditions, but in general they were built with five steps, the top course being 36in. × 36 in. The steelwork was designed to support on each track trains of cars weighing 80,000 lbs. each, 46 ft. 4 in. long over all, 32 ft. 10 in. long between truck centres, with a truck wheel base of 6 ft. 1 in.

The track is arranged as shown in Fig. 1. The sleepers or

Digitized by Google

ties are 6 in. × 8 in. × 8 ft. of sawed yellow pine laid on the top flanges of the longitudinal girders, which are 12½ in. wide. They are spaced 18 ins. apart, and every fourth tie is cut to 9-ft. length to provide support for the third rail insulators. The alternate long and short ties are secured to the girder flanges by ¾-in. × 7¾-in. hook bolts having flats washers and projecting nuts. The outer guard rail is a 6-in. × 8-in. timber cut in lengths of 24 ft. 8 in., and laid on edge 10 in. out from the gauge line of the rail. It is secured by ¾-in. bolts to the alternate ties, which are not hook bolted to the structure. The washers are cupped and counter-sunk. The inner guard rail is a 6-in. × 6-in. timber cut in the same lengths and placed 4 in. inside of the gauge line of the rail. It is bolted to alternate ties, which are hook bolted to the structure. The running rails are 80-lb. American standard section laid to standard 4 ft. 8½ in. gauge on 8 in. tie-plates throughout. They are fastened to the ties with two 5-in. screw-spikes, and are connected by continuous rail-joints.

The third rail on the double-track section, where the feeders are run in a cable box, as shown in Fig. 1, are of 40-lb. American standard section, supported on insulators mounted on every fourth tie, or at 6-ft. intervals. On a single-track loop at stockyards no provision has been made for feeders, and an 80-lb. third rail has been put in. A new form of vitrified clay insulator base has been used on this work instead of an iron base. These are secured to the long ties by four lag screws or wood screws. The third rail is located with its centre line 20⅛ in. out from the gauge line of the adjacent running rail, and with its top 11½ in. above the top of the tie. On double track they are placed inside, next to the cable box.

The cable box, which is covered throughout, forms a convenient and safe runway along the structure between the tracks. It is supported on 6-in. × 8-in. × 8-ft. ties laid across the inside girders between track ties every 4 ft. 6 in. The sides are 2-in. × 12-in. planks, and the top is made of 2-in. × 8-in. × 3-ft. 4-in. ship lap planks; the under side is open. On each cross-tie support are 2-in. × 4-in. × 8-in. blocks, which raise the cable insulator beams up from the cross-ties. These beams are 4 in. × 8 in., and carry 11 insulators in two rows staggered at intervals of 5¾ in. The insulators are designed to carry each a 500,000-circ. mil cable, 1¼ in. in diameter. Over each cable support is a trap door in the top planking consisting of three planks secured with 1-in. × 6-in. battens, which is fastened down with lag screws. This can be quickly removed for inspection, repairs, or when new cable is to be strung.

On curves the superstructure, as described above, varies somewhat. The outer running rail is elevated by bevelled shims cut in four sizes according to the radius of the curve where used. For curves over 700-ft. radius, the elevation is ⅞ in.

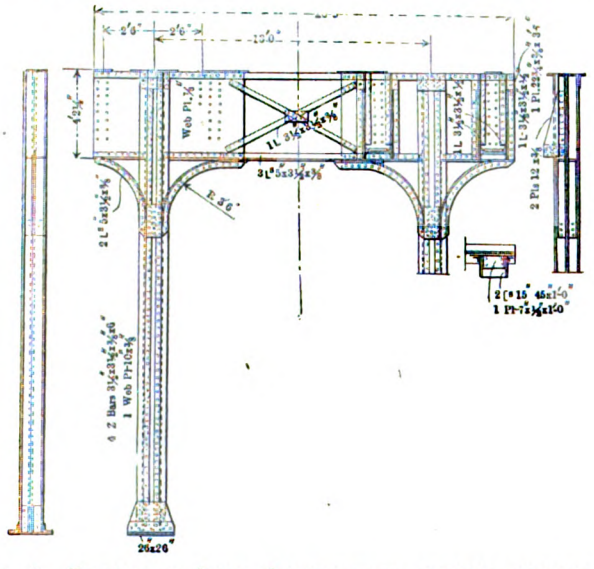

FIG. 2.—DETAILS OF STEEL CONSTRUCTION SHOWING EXPANSION JOINT.

between 500 and 700 ft., 1⅞ in. between 300 ft. and 500 ft., 3 in. and less than 300 ft. 4½ in. Extra steel guard rails are used on the inside of all curves. All special work is of a heavy pattern, and switch-points are protected by a safety guard rail. Rail braces are used on the sharpest curves. The sharpest curve on the double-track section is 150 ft. radius, but on the single-track loop the turns are made with a 109-ft. radius.

The 80-lb. third rail, which is being laid on the loop, is cut to 33-ft. lengths, and is spliced with malleable iron fish-plates, having four bolt holes. Each joint is bonded with two 500,000 circ. mil Crown bonds 15 in. long, which are pin-driven in the webs. The 40-lb. third rail used on the remainder of the line is cut to 30-ft. lengths, and is spliced with rolled fish-

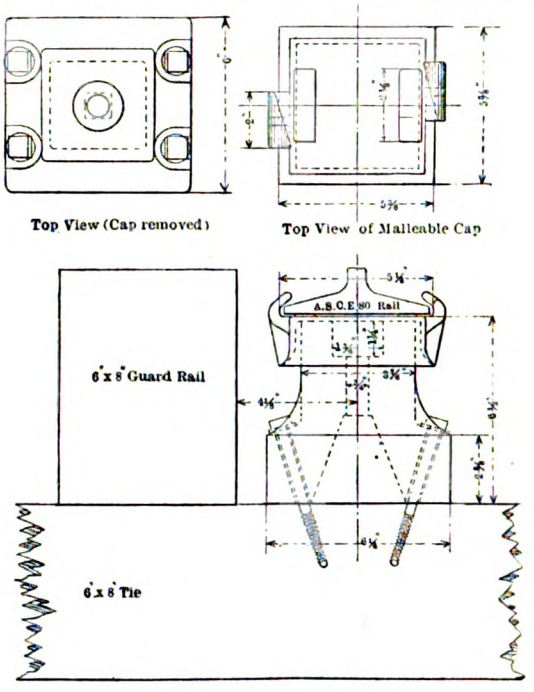

FIG. 3.—DETAILS OF THIRD RAIL INSULATOR.

plates. Two compressed terminal No. 0000 bonds from 2½ in. to 4 in. long are put in the webs at each joint. The track rails are bonded with No. 0000 compressed terminal bonds under the continuous joints.

The power-house is at Fortieth and State Streets, and the distribution of current is accomplished with only small transmission loss. One 1,500,000 circ. mil aluminium feeder cable has been laid from the power-house to the stockyards loop, and in addition one 1,000,000 circ. mil cable has been laid as far as the Union Avenue yard. Third-rail feeders are tapped into these cables about 1,800 ft. apart. The elevated structure has been carefully bonded for return current, and each of the track rails is bonded to the structure at intervals of about 400 ft. These bonds to the structure are staggered, so that with the four rails there is a bond about every 100 ft. No cross-bonding between rails has been put in. All bonds of every kind when applied have been coated with plastic amalgam.

City of London Engineer's Report.—In his annual report, the City Engineer (Mr. F. Sumner) states that the lighting of most of the main thoroughfares of the City by arc lamps was continued throughout 1907. The number of the older type electric lamps in use at the end of the year, at a cost of £26 each, was 400, a decrease of 39 being mainly accounted for by the substitution of new and cheaper flame arcs. The lamps were lighted on nine days during the year when fog or unusual darkness occurred, and the total additional cost was £43 12s. 11d. The number of defective electric lamps observed during the year was 99. Particulars with regard to the City subways show that the City of London Electric Light Co. has mains measuring 1 mile 1,481 yards, and the Charing Cross, West End & City Electricity Supply Co. 1 mile 1,721 yards in the subways, which also contain G.P.O. telegraph and telephone cables measuring 2 miles 1,145 yards, and a number of the department's pneumatic tubes. On the question of overhead wires, the City Engineer expresses the opinion that the Corporation, in its next General Powers Bill, should insert a clause making it obligatory upon persons who require to erect wires to give prior notice of their intention so to do, and at the same time submit proper plans. At present, he points out, any persons can fix wires (provided they comply with the Act) so long as they notify the Corporation within one month of their having done so. As a result, hundreds of wires have been erected in the City without any notice at all having been given, and it is only due to very careful supervision that new lines are detected. The overhead wires in the City continue to increase. During the year the number of private owners of lines was 133, and of companies 22. Both added considerably to their number during the twelve months, and the total stands at about 733,200 spans crossing public thoroughfares, compared with 731,500 in 1906, and 260,000 in 1899.

ELECTROMETALLURGY AND ELECTROCHEMISTRY

ACCORDING to T. Geilenkirchen in *Stahl und Eisen* (1908), **28**, 873, one of the most remarkable features of the Héroult process is the way in which sulphur can be eliminated from the charge. Tests of the product made from 1,000 successive charges in a Héroult furnace showed that the content of sulphur varied from 0·001 to 0·036 per cent. Of these tests 743 showed a percentage below 0·01 and 958, a percentage below 0·015. The author considers that two causes at least contribute to this elimination; firstly, manganese and iron sulphides are both of them soluble in the metal and in the slag, they therefore distribute themselves in furnaces between the metal and the slag, and when equilibrium is reached the final proportions depend upon their relative solubilities. Now at the higher temperature of the Héroult furnace the solubility of these sulphides in the slag is increased to a much greater extent than their solubility in the metal. In the second place, and this he considers is the more important, there is the powerful reducing action of the calcium carbide produced in the furnace. In the first place this effects the reduction of metallic oxides contained in the slag, the reduced metal being returned to the bath. The reduction of the sulphides by conversion into calcium sulphide is shown by the following equation :—

$$2CaO+3FeS+CaC_2=2CO+3CaS+3Fe;$$

The sulphide equilibrium is thus disturbed, consequently more sulphide enters into the slag from the bath, and this goes on progressively until finally almost complete desulphurisation is effected. From this it follows that a carefully worked charge from the higher furnace will never retain any appreciable proportion of sulphur, however high the original sulphur content may have been. Furthermore, the desulphurising action progresses independently of, and without altering, the proportions of the other constituents contained in the iron. For example, Thomas steel, when poured into the electric furnace to be finished, undergoes no change in its composition except that entailed in the removal of the sulphur; or if the foundry iron of low content in carbon, manganese, and silicon is being dealt with, and such an iron can hardly be obtained without having an excessive amount of sulphur, the Héroult furnace is *par excellence*, the furnace for refining inferior iron of this nature, independently of the amount of sulphur it may contain.

In the *Journal du Four Electrique et de l'Electrolyse* of July 15th, there is an interesting article upon the starting of the 750 kilowatt Keller electric furnaces at Unieux. The furnaces are capable of casting 8,000 kilograms of steel. The group of 750 kilowatt furnaces are run by a Westinghouse alternator which is worked by a steam compound engine of the Dujardin type, the boiler being on the Belleville system. The furnaces are placed near the Martin steel furnaces, so that the steel can readily be transferred from there to the electric furnaces. The Keller furnace is of the electrode type, the current passing from one electrode to the other. Each pole is composed of two electrodes in parallel, consequently there are four electrodes to each furnace, and the heating hearth is made to correspond with each of the four electrodes. Every electrode is worked by separate hydraulic machinery, so that the position of any one of them can be altered at will without effecting the others. The chief difference in the arrangement of the electrodes in the Keller furnace to that of the Héroult is that the electrodes do not dip into the slag, the arc striking above the molten mass, whereas with the Héroult they are beneath it. In order to regulate the tension, the electrodes of the same pole are simultaneously lowered. If there is any inequality between the tension of the opposite electrodes they can be independently moved, and the movement of the electrodes as they are all separate, is a very easy operation. The current intensity between the poles is also regulated by separately moving the electrodes. The current enters the furnace at the top of the electrodes, and is brought in by means of copper leads. The poles are so arranged in the four circuits so as to give the minimum of induction. The steel is produced in the Martin furnaces, and from there is poured directly into the electric furnace. The liquid steel is then refined, the time necessary for refining varying with the quality of the original steel, and also of the steel to be produced. At the end of the operation, the quantity of phosphorus+sulphur is less than 0·01 per cent. The installation at Unieux was started on April 22nd of this year, and the works have a capacity of 10 tons. Only four men are required to work a plant capable of producing 8 tons, so that the operating costs are light. At Unieux, 50,000 tons of fuel are employed to produce 6,500 tons of steel. About 10 tons of fuel are required to produce 1 ton of steel; this includes the amount required to raise steam and for the furnace operations. The article is illustrated with blocks showing the furnace in operation, and also with a general view of the works.

ELECTRICAL SCIENCE

British and American

Resistance of Silicon at Various Temperatures.—The results of an investigation of the effect of temperature upon the resistance of metallic silicon through a range of 600 degrees are given by F. G. Wick in the *Physical Review* for July. The material was in the form of rods about 3 millimetres diameter, and of various lengths from 3 to 27 cm. long. The rods were connected into an electrical circuit by means of iron wires fused into the ends of the rods by the oxy-hydrogen flame. On each rod, in turn, near either end, two independent copper-constantan thermo-junctions were bound, and the rod was passed into a porcelain tube heated by iron wire wound evenly over it. The position of the rod in the tube was adjusted so that the thermo-junctions showed the same temperature, and the resistance of the silicon was then measured by comparing the voltage drop between its ends with the drop between the terminals of a known resistance in series with the silicon. For temperatures below zero, the rod with its connections, was immersed in carbon dioxide and ether, and finally in liquid air. The experiments were carried out on four different silicon rods. The results show a lack of uniformity in the resistance of the different specimens, and also in the effect of temperature on resistance. This appears to indicate that the electrical properties of metallic silicon are very sensitive to changes in purity, physical constitution, crystalline structure, and, perhaps, other conditions. The average value of the specific resistance is $58,000\times10^{-6}$ ohm. per centimetre cube. The resistance temperature-coefficient was in all specimens negative from $-200°$ to $+200°$ C., but above the latter temperature was negative for some specimens and positive for others. The author has examined into the possibility of utilising silicon as an agent for electrical heating, but the extreme brittleness of the substance has prevented success in this application.

Continental

Thermoelectric Detectors.—In connection with Tissot's recent descriptions of "thermoelectric" detectors, E. Branly points out, in the *Comptes Rendus* for July 13th, that for years before Tissot he used combinations containing tellurium as detectors in wireless telegraphy. Such combinations included tellurium-steel, tellurium-silver, tellurium-gold, and a combination of tellurium with mercury and steel. The more usual arrangement was a tripod of tellurium or some telluride on a polished steel plate or disc. The circuit consisted of a telephone, a cell giving 0·1 volt, and the tripod and disc. That the effect is not thermoelectric was proved by the fact that the tripod may also be provided with steel feet without losing its efficacy, but tellurium is both more sensitive and more regular in its action. Comparing such detectors with the electrolytic type, Branly remarks that though the latter are the more sensitive, he prefers the tellurium detector for use in the laboratory. The first employment of tellurium for wireless purposes dates back to 1891, when Branly used selenium and tellurium filings for his coherer or "radio-conductor."

Wireless Telemechanics.—Telemechanics, or the control of mechanism at a distance without ordinary methods of transmission, is still in a very undeveloped stage, chiefly owing to the danger of the mechanism getting started or stopped accidentally by some disturbing impulse. Edouard Branly has been working for some years at perfecting the methods. Some time ago he described a method of guarding the telemechanism against accidental spark-waves. But since the advent of commercial wireless telegraphy, the real danger has lain in the interference by wave-trains of considerable duration. In the *Comptes Rendus* for July 20th, Branly describes an apparatus designed to obviate this danger also. The control is divided into five recurrent periods, to each of which is assigned a separate function. Unless each function is carried out in the succession appointed, the mechanism stops. The periods are governed by the motion of a rod having three soft iron sections, which are sucked into three different solenoids. The first period is used for starting, but if the start is false (of which a bell warns the operator automatically), the second period may be used for stopping. Otherwise, it is left unused.

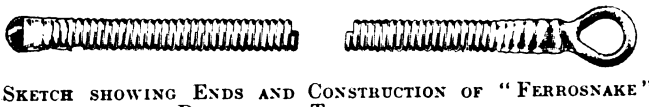
Electric Double Refraction in Nitrobenzene.—A. Cotton and H. Mouton describe some further remarkable optical properties of nitrobenzene, shown when immersed in an electric or magnetic field. The particulars are given in the *Comptes Rendus* for July 20th. The difference in the refractive indices for the ordinary and extraordinary rays varies in a magnetic field in

Digitized by Google

the same sense as it does in quartz, but more rapidly. The variation is quite regular throughout the visible spectrum. The electric double refraction is very great, and the authors go so far as to say that it is 97 times as great as it is in carbon bisulphide. As regards the visible spectrum, the dispersion of the magnetic double refraction is the same as the electric double refraction. The authors go on to consider the bearing of these observations on the theory of the Faraday and Kerr effects, and conclude that we have to do with a true orientation of the molecules of the liquid themselves. The effects are of the same kind in other bodies belonging to the aromatic series, but not nearly so large.

A NEW DRAWING IN "TAPE"

THE Armorduct Manufacturing Co., Ltd., have just introduced a new appliance which should prove of great use to wiring contractors in the shape of an improved form of draw in "tape" for drawing in conductors into conduit tubes. The apparatus has been given the name of the "Ferrosnake," and is constructed in an entirely novel way. Difficulties are frequently experienced in the drawing-in of electrical conductors, by reason of the sticking of the draw-in tape employed. To meet this difficulty the "Watch" tape replaced the drawing-in wire, but the ordinary "Watch" tape is exceedingly brittle and liable to kink, is expensive and mechanically weak. It was to meet these objections that the present appliance was



SKETCH SHOWING ENDS AND CONSTRUCTION OF "FERROSNAKE" DRAWING IN TAPE, FULL SIZE.

designed. The general appearance of the "Ferrosnake" is seen in the accompanying illustration, which shows the ends full size and to scale. Galvanised steel wire is used for its construction formed into a tight coiled spring, which is of enormous strength, while it can be bent in all directions like a flexible shaft. Its nature is, however, such that it cannot possibly kink, tear, stick, twist, or knot while being pushed through a tube, and an important feature is that if it meets a projection in the conduit or conduit fittings, a slight twist at its extreme end will spring it free. The diameter is about 5/32 inch, and it is supplied in three lengths, 35, 70, and 100 ft.

Proposed London Central Council.—Among the objects of a proposed new central council for London, the creation of which will be urged upon the Prime Minister after the reassembling of Parliament in October, is an arrangement whereby all electrical and similar undertakings shall fall ultimately into its possession. The idea is said to be to make the present County of London one borough with a municipal council of 250 members, presided over by a Lord Mayor.

Tramway Accidents.—On Thursday a car belonging to the Stalybridge, Hyde, Mossley, and Dukinfield Joint Tramways Board jumped the points at Stanley Square, Stalybridge, and crashed into a surgery, knocking down the front part of the entrance. The damage to the car was not serious, and none of the passengers were hurt.

A double-deck tramcar on the Mexbrough and Swinton system got out of control of the driver on Thursday when near Rawmarsh. The car ran away on Warren Hill, leaving the rails at the bottom, breaking through a wall, and dropping into a garden about 10 ft. below. There were about 60 miners on the car, but the most serious injury was a broken collar bone. This particular system is at present being converted from the surface contact to the overhead trolley system, but the conversion has not reached the point where the accident took place.

The British Association.—Arrangements are well advanced for the holding of the 78th annual meeting of the British Association in Dublin from September 2nd to September 9th next, under the presidency of Prof. Francis Darwin, F.R.S. We give below the officials of Sections A and G in the proceedings, of which most of the electrical interest is concentrated. Section A.—*Mathematical and Physical Science:* President—Dr. W. N. Shaw, F.R.S.; Vice-Presidents—Prof. A. E. H. Love, F.R.S.; Right Hon. the Earl of Berkeley, F.R.S., Mr. F. Purser, Prof. W. S. Burnside, Prof. H. H. Turner, F.R.S., and Prof. W. F. Barrett, F.R.S. Secretaries—Prof. A. W. Porter (Recorder); Prof. E. T. Whittaker, F.R.S., Mr. W. Geoffrey Duffield, Dr. L. N. G. Filson, Mr. E. Gold, Prof. J. A. M'Clelland. Section G.—*Engineering:* President—Mr. Dugald Clerk, F.R.S., M.Inst.C.E.; Vice-Presidents—Prof. Silvanus P. Thompson, F.R.S., Sir Howard Grubb, F.R.S., Sir Charles Douglas Fox; Secretaries—Mr. W. A. Price (Recorder), Prof. E. G. Coker, Mr. H. E. Wimperis, B.A., Prof. W. E. Lilly.

CATALOGUES AND PAMPHLETS RECEIVED

ELECTROLYTIC VALVE APPARATUS.—Messrs. Siemens Brothers & Co., Ltd., have issued a supplement to their catalogue of electromedical apparatus. This supplement describes the Siemens patent electrolytic valve apparatus for rectifying alternating current, and outfits are listed and illustrated for its application to X-ray and high-frequency work, charging of accumulators, electro-plating baths, and mercury vapour lamps. The reliability of the apparatus is safeguarded by the employment of a patent testing switch by means of which the condition of the valve apparatus may be determined at any time. The apparatus should be found useful by those who, up to the present, have been precluded from employing in an efficient manner processes requiring continuous current owing to their electric supply being an alternating one. The coils included in the X-ray outfits are specially constructed for use with the Wenhelt interrupter, and a high degree of efficiency is claimed for the combination.

CABLES AND WIRES.—Messrs. Johnson & Phillips, Ltd., of Charlton, have issued a new edition of their catalogue of "Vulcanised Indiarubber-Covered Cables and Wires." This is very complete and well-arranged, and contains particulars of a large number of varieties of material, both in accordance with the standards of the Cable Makers' Association and of "non-associated grades," including also Paterson's fireproof cables.

SPECIAL CASTINGS.—We have received a booklet, written by Mr. Charles Barker, describing the Borshardt casting process, which we understand is in extensive use in France for producing a metal of great homogeneity and thoroughly malleable, without any process subsequent to the actual casting. The main features of the process are: The adoption of a special furnace, which is patented, producing an excessive heat, of a uniform temperature of about 2.000° throughout, the introduction during the fusion of the metal of chemical products into the metallic mass in order to refine it and give the necessary qualities to the metal, and the use of a special coating in order to reduce in a considerable manner the wear and tear of the melting pots or crucibles, and to keep up and preserve the interior sides of the furnace, which reduces the current repairs to a low basis, and thereby procuring a low cost of production.

GAS ENGINES.—A new gas engine and suction plant catalogue has been issued by Messrs. Kynoch, Ltd., of Birmingham. Particular attention has been paid in the design of the Kynoch gas engines to points enabling very steady running to be obtained, and in the larger engines, cylinders of excessive size with their attendant disadvantages are avoided by a tandem arrangement. In engines from 80 h.p. upwards the pistons are cooled by a "trombone" device, and the exhaust valves are water cooled on the pump system. Particulars and illustrations of engines from 5 to 580 B.H.P. are given, all of the horizontal type, with brief descriptive particulars of the Kynoch suction gas plant, followed by abridged specifications. The usefulness of the catalogue is enhanced by full tables of shipping weights and measurements.

Erratum.—By a clerical error on page 176 of our last issue we referred to Mr. R. Borlase Matthews as Chairman to the proposed electrical league instead of Honorary Secretary.

Commutating Poles for Continuous-Current Traction Motors.—In general the application of commutating poles to small traction motors of from 30 to 35 h.p., as used on the ordinary 500- to 600-volt tramway systems offers no particular advantages. In certain cases, however, where wide variations in speed are required, the use of commutating pole motors with speed control by varying the main field may be advisable. An article in *Elektrische Kraftbetriebe und Bahnen* describes some experiments made on the tramway line between Mainz and Wiesbaden with two cars of exactly the same pattern with the exception that the motors of one car were fitted with commutating poles. About four miles of the line between Mainz and Wiesbaden is on a private way, and on this portion of the line the speed of the cars could be increased with advantage to over 30 miles per hour. The same cars must be capable of running economically at the slow speed usual in towns. Experiments proved that whereas the speed of the car equipped with commutating pole motors could be economically varied by field regulation (and, of course, series parallel working) between the limits of 31 and 13 miles per hour, the limits in the case of the other car were 31 and 18 miles per hour. This latter speed would be too high for ordinary road use. The experiments also showed that the alteration from series to parallel running could be performed easier in the case of the former car. The bow could be withdrawn from the line and the rheostatic brakes applied without injurious sparking occurring at the commutators of the commutating pole motors when running at the maximum speed of 31 miles per hour.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published July 30th, 1908

A full list of these was published in our last issue. The following are abstracts of the more important specifications.

1907 Patents

16,431. **The "Stearn" Multiple Metal-Filament Lamp.** C. H. Stearn and C. F. Topham. This lamp, which was described and illustrated in Electrical Engineering, Vol. III., page 651, consists of a number of lamp units, each of which is a single loop lamp. A number of these lamp units are arranged in series on a common base, and arrangements are made so that should one filament burn out, a carbon or other resistance is put in as a shunt across the burnt-out filament, thus keeping the lamp, as a whole, alight and permitting the ready detection and replacement of burnt-out lamp unit. Instead of substituting a resistance for a burnt-out unit another lamp, normally short-circuited, may be put in circuit and the burnt-out unit short-circuited. Four claims, seven figures.

17,815. **Joints between Metal Filaments and Leading-in Wires.** A. C. Hyde. The leading-in wires of electric lamps may be of copper, iron, nickel, or platinum. To produce a conducting joint between the leading-in wire and the tungsten or other filament, the filament is first secured to the wire with a paste made from a metallic powder and a gelatinous metallic oxide. Copper, tungsten, or nickel powder may be used with a precipitated oxide of either copper or nickel. To reduce the paste and sinter the joint together the leading-in wire is connected to one terminal of the secondary of a 1,000-volt transformer. An electrode connected to the other terminal is brought near the joint. The arc formed reduces the oxide and a good metallic joint is obtained. The operation must be performed in an atmosphere of hydrogen. A jet of hydrogen may be used instead of the arc. Two claims, one figure.

1908 Patents

10,121. **Speed Regulation of Single-phase Commutator Motors.** Allgemeine Elektricitäts Gesellschaft. This invention relates to the speed regulation of that type of single-phase motor in which the working winding, which is supplied direct from the secondary of the main transformer, is in series with the auto-transformer which feeds the exciting winding. In this method of control the secondary of the main transformer and the primary of the exciter transformer are so interconnected that the number of turns in the primary winding of the exciter transformer is decreased and the transformer ratio thus increased at the same time as the potential of the secondary of the main transformer is lowered. Thus at speeds higher than the synchronous speeds it is possible to lower the impressed motor voltage, and thus reduce the core loss and improve the commutation. Two claims, one figure.

11,534. **Manufacture of Metal Filaments.** Siemens & Halske Aktiengesellschaft. A process for removing from metal filaments the carbon which remains from the binding agent. The filament to be treated is connected with a source of supply and placed in the receiver of an air-pump, which also contains a dish holding glacial acetic acid. After a sufficient vacuum has been produced, the glacial acetic acid evaporates, and if now the filament is caused to glow the carbon is rapidly removed. Two claims.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.

Names in brackets indicate communicators of inventions from abroad.

Summaries of the more important of these patents will appear in our next issue.

1907 Patents

11,070, British Thomson-Houston Co. (*Allegemeine Elektricitats Ges.*). Motor-controlling switchgear.
15,834, La Cour. Starting and controlling induction motors on a single-phase supply.
16,252, Rojcsik. Means for electrically operating tramway points.
16,372, McPhail. Insulation of cables, generators, or motors.
16,461, Varley. Make and break contacts.
16,503, Deutsche Gasgluhlicht Akt.-Ges. Method of attaching tungsten filaments in glow lamps.
16,600, Schreiber. Electrically-propelled vehicle.
17,584, Harding. Switches for electric bells.
18,022, British Thomson-Houston Co. (*General Electric Co.*). Controlling devices for electric circuits.
15,753, Cole. Means for working electric signs.
18,762, Mackenzie. Indicating and recording apparatus.
19,113, Pendlebury, Pendlebury, & Pendlebury. Conduits for electric wiring.
20,619, Escaré & Damey. Lamp holder.
21,174, Siemens Bros. Dynamo Works, Ltd. (*Siemens-Schuckertwerke Ges.*). Switches, relays, and measuring instruments.
21,699, Denieport. Magnetos for explosion engines.
23,043, Timar & Von Dreger. Arc lamps.
23,322, Boucher & Mitchell. Electric switches.
23,880, Felten & Guilleaume Lahmeyerwerke Akt.-Ges. Means for generating direct current.
24,231, British Thomson-Houston Co. (*General Electric Co.*). Systems of electric distribution.
24,387, Russell & Milligan. Apparatus for recording signals in mines.
26,144, Eastwood. Lifting magnets.
26,404, Siemens Bros. Dynamo Works, Ltd. (*Siemens Schuckertwerke Ges.*). Speed-controlling apparatus for electric motors.
26,797, Siemens Bros. Dynamo Works, Ltd., & Bolton. Starting switch sets for polyphase motors.
27,764, Gibbons. Helm signal telemotor apparatus.

1908 Patents

877, Siemens Bros. Dynamo Works, Ltd., & Clift. Automatic stopping devices for electric lifts or hoists.
1,799, Bassano. Means for controlling the electric motors of gramophones.
2,340, Malley. Vulcanising apparatus.
2,404, Le Pontois. Magneto generators.
3,159, Frey. Link-suspension device for incandescent bodies.
5,950, Barton & Sons, Ltd., Barton, & Harper. Means of coupling electrical conduits.
6,051, Siemens & Halske Akt.-Ges. Process for hardening tantalum.
6,229, Digby. Arc lamps for theatre stages.
6,453, Jirotka. Production of ozone.
7,107, Eisemann. Sparking plugs.
7,494, Fessenden. Wireless signalling.
8,471, Verity's, Ltd., & Smith. Electric heating apparatus.
8,769, Blum. Sparking-plug.
9,289, Aron. Multiple tariff electricity meters.
11,134, Steckel & Thomson. Electrical induction clutches.

Complete Specifications open to Public Inspection before Acceptance.

1908 Patents

4,030, Tidnam. Telegraph pole.
9,638, Siemens-Schuckertwerke Ges. Three-phase commutator machines.
12,682. Allgemeine Elektricitäts-Ges. Arc lamps.
12,720, Soc. Française d'Incandescence par la Gaz (*Système* Auer). Manufacture of incandescent electric lamp filaments.
13,134, Usine Genevoise de Degrossissage D'Or. Electrolytic cells for separating metals or alloys.
13,772, Bénard. Electrically-controlled valve for gas.
14,610, Berlinger. Portable vulcanisers.
14,850, E. Goosens Pope & Co. Manufacture of plastic masses of oxide of tungsten.
14,897, Breslauer. Method of compounding alternating-current generators.

Application for Amendment

Further particulars and instructions as to procedure in opposition to amendment will be found in the Official Journal of the Patent Office of July 29th, 1908.

24,572 of 1904. De Dion Bouton (1907), Ltd., seek leave to amend the specification numbered as above, granted to Albert de Dion and G. Bouton, for "Electric igniters for internal combustion engines," for the purpose of more clearly defining the invention.

Expiring Patents

The following patents expire during the current week, after a life of fourteen years :—

15,129 of August 8th, 1894. **Evacuation of Lamp Bulbs.** A. Malignani. A process for producing a vacuum in lamp bulbs and consisting in first producing a 2 mm. vacuum by means of a vacuum pump, after which the filament is raised to incandescence. The gases given off by the filament are caused to unite with other gases produced by warming sulphur, or arsenic previously introduced into an extension of the bulb. A solid or liquid precipitate is formed in the extension.

15,276 of August 10th, 1894. **Electrolytic Cells.** M. Kiliani, W. Rathenau, and the Elektrochemische Werke Ges. An acid- and alkali-proof diaphragm vessel consisting of a permeable membrane held between latticework frames made of acid-proof material.

LOCAL NOTES

ABERDEEN: *Agreement with Tramway Co.*—The renewal of the agreement between the Corporation and the Aberdeen Suburban Tramways Co. for a supply of electricity to the latter is still under discussion, and it is possible that a conference will be held very shortly to settle the points in dispute.

AUSTRALIA. *Sydney: Tramway Strike.*—A *Reuter* telegram states that the Chief Commissioner of the Railways addressed a mass meeting of the strikers on Wednesday last week, and as a result 500 men asked to be reinstated.

Adelaide: Tramways.—The annual report of the Engineer to the Municipal Tramways Trust, Mr. W. G. T. Goodman, has been issued. Dealing with the preliminary work of the Trust, the engineer points out that he sub-divided the work into 45 contracts, 31 of which related to the main construction work. He is now engaged on the preparation of the plans and specifications for the power station buildings and equipment, the remainder of the rolling-stock, and the overhead transmission lines. The two most important contracts that have been let are for the construction of the permanent way to Messrs. Smith & Timms, and for the overhead construction work to the British Insulated & Helsby Cables, Ltd. The next question to be faced is the organisation of the traffic staff, and Mr. Goodman states that his object will be to take over the present horse-car employees as far as possible. He is, however, preparing a special report upon this part of the work.

Hawthorn (Victoria): Electric Lighting.—Mr. W. Corin is to prepare a report with regard to an electrical installation.

BECKENHAM: *Supply of Electricity Bill.*—The Electricity Committee have received a copy of a circular which is being sent around to municipalities by the Town Clerk of the Shoreditch Borough Council, proposing a deputation to the Board of Trade urging the re-introduction of the Supply of Electricity Bill. The Committee recommend the appointment of two of their members to join this deputation.

BELFAST: *Harbour Tramways.*—The harbour tramway is now complete, and an experimental run was made over it last week from County Down terminus to the end of Queen's Road. The Board of Trade has been notified that the line is ready for inspection.

BIRMINGHAM: *Tramway Extension.*—A ratepayers' meeting has been held with regard to the proposal to urge the Corporation to extend their tramway system into Stechford, and a resolution was passed asking the Yardley Rural District Council to open up negotiations with Birmingham with this object in view.

BIRKENHEAD: *Tramway Finance.*—The report of Mr. W. Wyld, the Borough Electrical Engineer and Tramways Manager, for the year ended March 31st, 1908, shows a total income of £55,936, and working expenses £54,972. After meeting capital charges, however, there is a net deficiency of £914, which has been largely brought about by the increase in cost of fuel, in maintenance of rolling stock, and in capital charges, which in all amounts to £2,445. The report makes mention of the fact that there were no fatal accidents, nor any of a serious nature during the year.

BRIGHTON: *Power Supply.*—The London, Brighton, and South Coast Railway Co. having proposed to introduce electric power into their Brighton works, have agreed with the Corporation Electricity Supply Committee to take current upon terms which now await the sanction of the Council. The general conditions of the agreement are that the railway company will take a supply for five years, which will be disconnected between 5.30 p.m. and 8 a.m. during December and January, the terms of payment being a fixed charge of £750 per annum, *plus* 0·56d. per unit. There is a clause in the agreement that in the event of an increase in the price of coal above 16s. per ton, a proportionate increase in price will be paid by the company for the energy. Mr. J. Christie, the Borough Electrical Engineer, reports that the company are fixing motors of a total capacity of 1,500 h.p., which will be run in such a way as to give a continuous load on the electricity works during the day-time of from 400 to 500 h.p. It is estimated that the consumption will be from 500,000 to 750,000 units per annum, and that the revenue will be from £2,000 to £2,500. The cost of laying mains to connect the works with the North Road sub-station is £3,363. Mr. Christie strongly recommends the acceptance of the agreement, which also has the support of Mr. Arthur Wright, the consulting engineer.

BRISTOL: *Electricity Accounts.*—At the meeting of the Corporation on Tuesday last week, Alderman Pearson, the Chairman of the Electric Lighting Committee, presented the accounts of the electricity undertaking, which we gave in our last issue. He said he had to report that the general growth of the undertaking had been satisfactory as to amounts, although not quite so satisfactory as to profits. They had an increase of nearly £7,500 in income and about £2,040 in profits. Their customers were about 80 short as compared with the increase of the previous year, whilst the lamp connections also had not been so good, there being 16,900 in 1907 and 11,600 in the year just ended. Similarly, the horse-power added to the motor load had only been 1,300 against 1,833 last year. There had been a most satisfactory increase in output, however, which enabled them to considerably reduce the cost to the consumer. One of the main reasons for the profits having shrunk was a very material increase in the sinking fund charges, which had grown by £2,200. In addition, they had a very ridiculous charge put upon them in respect of the wages of workmen employed on capital duties, because they happened to be permanently employed. After a short discussion the Electricity Commitee's report was adopted.

CROYDON: *Electric Supply Charges.*—The following reductions in the charges for current have been agreed to by the Corporation, to take effect, as regards the tramways, from the June quarter, and as regarding public and private lighting from the September quarter, 1908:—(*a*) flat rate at 5d. to be reduced to 4½d.; (*b*) heating, cooking, and basement lighting, flat rate at 2½d., heating and cooking to be reduced to 1½d.; (*c*) public lighting, the price per lamp per annum for arc lighting to be reduced £1 per lamp; (*d*) power with time switch during evening load at 3d. and 1½d. to be reduced to 3d. and 1d.; (*e*) traction, first 1,000,000 units at 2d., excess at 1½d.

DARTFORD: *Light Railways.*—The accounts for 1907-8 show a balance of £1,472, after meeting interest and sinking fund, &c. The number of passengers carried was 2,055,033, and the car miles run 317,127. The number of Board of Trade units taken from the Council's electricity works by the lessees of the lines, Messrs. J. G. White & Co., was 428,600.

DUBLIN: *Tram Fares.*—A letter has been addressed to the Town Clerk, pointing out that under Section 68 of the Corporations Tramway Act of 1904, the Corporation only have the right of fixing tram fares annually, and that this having been done at the commencement of the present financial year, the inauguration of a system of halfpenny fares is illegal. The letter in question, which has been written on behalf of a number of ratepayers, contends that the Corporation must at once revert to the fares fixed at the commencement of the financial year, otherwise the Ratepayers' Association will put the matter before counsel with a view to taking such proceedings as may be advised.

DUNDEE: *Albert Institute Lighting.*—The supply of electrical energy for the lighting of the Albert Institute is now taken entirely from the Corporation mains, the independent plant having been dismantled. Mr. H. Richardson, City Electrical Engineer, has acted as adviser for the new installation. The lighting includes three 10 ampere "Excello" arcs of 2,700 c.p. each, and four 25 c.p. tantalum lamps. It is estimated that a saving of £130 per annum will be made under the new arrangement.

DUNFERMLINE: *Transfer of Provisional Order.*—An agreement has been drawn up between the Town Council and the Fife Electric Power Co. for the transfer of the Council's electric lighting order. The agreement gives the Council the option of re-purchasing the undertaking at the expiration of 30 years, or every subsequent period of seven years. In the event of such purchase taking place the Council is to pay the company £5 for every consumer supplied. Sir Alexander Kennedy is named in the agreement as the arbitrator between the company and the Council upon all matters arising out of the agreement.

DUNSTABLE: *Provisional Order.*—Messrs. Foote & Milne have notified the Council of their intention to apply to the Board of Trade for an electric lighting provisional order for the district.

EDINBURGH: *Electric Lighting Surplus.*—At the meeting of the Corporation last week the Electric Lighting Committee's recommendation to transfer £9,794 of the surplus electric lighting profits to the relief of the rates was carried.

FRANCE: *Electric Traction.*—The Chamber of Deputies have approved the construction of three railway lines which will complete the Midi Railway system in the Departments of Gers, Hautes and Basses Pyrénées and the Landes. The first of the lines, from Auch to Lannemezan, will be of normal gauge and cover a distance of 70 kilometres. The second line, 52 kilometres long, is to be of metre gauge and will connect Castelnau-Magnoac with Tarbes, passing by Trie, Cabanac, Aubarède, and Pouyastruc, through a series of valleys to the main line from Toulouse to Bayonne, which it will join at Marcadieu. The third line will be constructed from Arreau to Saint-Lary-Vielle-Aure, to prolong the existing line from Lannemezan to Arreau. This will be of normal gauge and about 11 kilometres long. These lines, which are to be run by electrical traction, will receive their power from the hydro-electrical works at Eget. The waters of the Oule are to be stored by means of a dam erected in the Aure Valley, and will pass through a canal, 5,800 metres long, to the Eget Plateau, whence they will be forced through conduits to the power-generating works near Tramezaygues.

GUERNSEY: *Telephone Anniversary.*—The tenth anniversary of the opening of the State telephone service was celebrated last week. The number of stations now connected to the system is 1,698, which is equal to one for every 23·8 persons. The capital expended upon the system to date is £51,560.

Digitized by Google

HESTON AND ISLEWORTH: *Condition of Tramway Track.*—The District Council has appointed representatives to attend a conference of Local Authorities, which is being convened by the Hampton District Council to take into consideration the condition of the tramway track with a view to united action being taken against the London United Tramways Company.

ILFORD: *Electricity Accounts.*—The financial result of the electricity undertaking for the year ended March 31st, 1908, is a deficit of £375. The total revenue amounted to £27,637, and the expenditure to £17,891. Of the amount carried to net revenue account, sinking fund absorbed £4,364, and interest on mortgage debt £5,124, whilst the payment to the Tramways Committee as instalment and interest on machinery used for generation of electricity charged to tramways capital account amounted to £557. The capital expenditure at the end of the year was £154,601. The number of units sold was 3,046,728, and the average price obtained was 1·90d. per unit. The percentage of gross profit, namely, £9,671, to average capital was 6·37. There are now 3,045 against 2,836 for the previous year. The maximum load was 1,604 kw. against 1,675 kw., and the load factor was 21·68 per cent. compared with 20·7 per cent. The total working costs amounted to 1·17d. per unit, an increase of 0·04d. over the previous year.

LONDON: *Greenwich: Treatment of Sewer Gas.*—In a report upon Major Cardew's experiment of deodorising sewer gases by means of an ozone generating apparatus, suspended in each manhole, and supplied with energy from the street mains, the Public Health Committee state that although the apparatus might deal with the normal flow of sewer gas, they doubt whether it would treat effectively the gas coming from the sewers at high pressure. Further experiments would be costly, and of uncertain advantage, and they had decided that no further expense should be incurred in the matter. Major Cardew estimated the cost of a single installation, including cables and street work, at £30, and the upkeep, provided not less than 20 apparatus were installed, at £3 per installation per annum.

Hammersmith: Electricity Accounts.—In submitting the accounts of the electricity department for the year ended March 31st, 1908, the Borough Accountant states that the aggregate amount of capital borrowed at that date was £279,951, and net amount expended £290,221. Of the above total capital indebtedness, an amount of £49,298 had been redeemed at termination of financial year, in addition to an amount of £153 charged in the accounts as a reserve for redemption of capital overdraft. This redemption represents 17·6 per cent. upon the amount of loans taken up, and the amount of unpaid borrowed capital at end of year was, therefore, £230,653. Of this total capital outlay the amount redeemed during the year was £10,389, or 3·58 per cent. The revenue account shows a substantial increase over the previous year. The gross income has been £40,428, whereas at corresponding date last year it was £37,302. The total number of units sold for private purposes during the year was 4,406,671, and the revenue obtained therefrom averaged 1·85d. per unit. During the previous year the total units sold was 3,657,610, and the average revenue obtained was 2·01d. per unit. The percentage of increase shown by the units sold over the previous year was 20·4. The actual increase in income derived from private lighting supply has been £3,501, and from public lighting supply £152. The revenue from meter rents has been £191, an increase of £17 when compared with last year, whilst revenue derived from miscellaneous receipts has reached £1,340. The working expenditure for the year has been £21,896, and the gross surplus £18,531. This gross profit represents a percentage of 6·4 upon amount of capital expended upon the undertaking. Last year the gross profit was 5·6 per cent. upon amount of capital expended, and in the previous year the corresponding gross profit amounted to 6·13 per cent. After meeting charges of interest, &c., and temporary overdraft on capital account, and writing off a sum of £153 for irrecoverables, the net profit made for the year was £13. The corresponding sum last year was £14. During the past year a further amount of £3,000 has been contributed by the undertaking in relief of Borough rate. The total contribution to date thus made from its accumulated revenues has been £7,000. The reserve fund of £2,500 formed pursuant to resolution of the Council of June 17th, 1903, has been added to by a similar amount placed to its credit during the year. The reserve fund thus stands at £5,000.

Islington: Sinking Fund Charges.—The Finance Committee of the Borough Council have considered a suggestion by the London County Council that a special reserve fund be set apart in order to provide that loan repayments in respect of machinery, plant, mains, &c., shall have been completed at the expiration of the usual life of such equipment, viz., at an earlier period than the 42 years, which is the period the loans were originally granted for. The Committee think, however, that a departure from the present system of repayment is not desirable.

Marylebone: Electricity Accounts.—The financial statement of the second year of the electricity undertaking shows that the gross income was £161,492, compared with £158,459 for the previous year. Of this working expenses, management, &c., absorbed £50,920, and special expenses brought the total charges on revenue account to £57,659. The costs per unit sold averaged 1·389d. compared with 1·45d. for the previous year. Notwithstanding the higher price of coal during the latter part of the year, generation costs were reduced from 0·77d. to 0·731d. The average price charged for current to private consumers worked out (including meter rents) at 4·38d., compared with 4·7d., the average for the previous year, and 5·15d. for the year ended March, 1906. The net increase in the number of units sold was 629,175. There is a deficiency on the year's working of £3,136. The shortage, say the committee, is mainly due to the lower average price now obtained. The large increase on the sales of current for power purposes and for other cheaper classes of supply, together with the increase in the number of consumers now obtaining a lower average price under the maximum demand system have, combined, resulted in a temporary deficiency between income and expenditure. The committee feel assured, however, that the lower charges now made for the supplies referred to are creating a fresh market for the development of the undertaking, and that the tariff generally is perfectly sound. The balance in hand at March 31st, 1907, was £29,325, out of which the deficiency will be met, leaving a credit balance at March 31st last of £26,189.

Stepney: G.B. Surface-Contact System.—At the meeting of the Borough Council on Thursday the report of the Works Committee recommending the Council not to give its consent to the overhead system in the Mile End Road was adopted. Mr. H. H. Gordon gave notice to bring forward at a future meeting the following resolution :—"That this Council views with feelings of great dissatisfaction and alarm the proposals of the London County Council to continue the experiment of electric traction in the main road of the borough, the results of which show, as the Highways Committee themselves state, that it will not be practicable to continue the use of the system consistently with the safety of the public using the roads, and the efficient working of the tramway under the circumstances prevailing on the road, and that copies of the resolution be sent to the Board of Trade, the local members of Parliament, and local members on the L.C.C." He said that apparently without any fresh information the London County Council had in the early hours that morning reversed the recommendation contained in the Highways Committee's report.

St. Pancras: The Patents Act.—The Parliamentary and General Purposes Committee have reported that the Electricity and Public Lighting Committee have called attention to the new Patents Act, which makes it compulsory for all patented goods intended for sale in this country to be manufactured here. It is stated that as a result many foreign firms have rented premises in the metropolis for manufacturing purposes, and it is suggested that the Council should advertise in British and foreign papers pointing out the facilities offered in St. Pancras in the way of cheap electric power for setting up factories.

LOUGHBOROUGH: *Electricity Accounts Deficit.*—At the monthly meeting of the Town Council on Wednesday last week it was stated that the balance-sheet of the electricity undertaking for the year ended March 31st, 1908, had turned out more unsatisfactory than had been expected, and a sub-committee had been appointed to go thoroughly into the accounts. When this had been done the annual statement would be presented to the Council.

MADEIRA: *Telephone System.*—A British Consular report states that the question of providing a telephone system in Madeira is still being argued for and against. The question appears to be whether the system shall remain a Government one or not, and the expenses have to be looked into and considered most carefully. The general opinion, however, is that whatever plan be adopted it would well repay the outlay.

Electric Light.—This still continues in the hands of one company. It has been rumoured that a British company was to take over the whole plant and erect a new installation.

MAIDSTONE: *Engineer's Remuneration.*—The Electricity Committee recommend that, as from March 25th, 1908, Mr. E. E. Hoadley, the electrical engineer, be paid a salary and commission calculated as follows :—When the total cost per unit (excluding capital charges) shall be one and one-eighth pence, the salary shall be £300 per annum, and for each £100 saved to the committee through the reduction in cost per unit sold a bonus of 20 per cent. per annum. In all cases the salary for the financial year ending in March shall be calculated on the cost of the preceding financial year. This arrangement was to be subject to the following clauses :—(*a*) The usual coal clause; (*b*) if the committee at any time should decide to buy meters or other capital goods out of revenue, they shall adopt the procedure recommended by the Local Government Board, viz., keep the amounts so spent as a separate account which shall be extinguished each year out of the profits. The recommendation was adopted at the last meeting of the Corporation.

MONTEVIDEO: *Tramway Extension.*—A cable advice has been received that a further 20 miles of single track have been opened upon the electric tramway service, making a total of 75 miles of single track in operation by electric traction out of a total of 80 miles.

MORECAMBE: *Purchase of Tramways.*—A special meeting of the Town Council was held on Wednesday to consider the question of purchasing the undertaking of the Morecambe Tramways Co. It was reported that the Corporation valuers had valued the system at £7,661, whilst the company's valuers put

Digitized by Google

the value at £15,952, with further sums for plant, &c. The Tramways Committee have rejected the company's figure, and the Council was asked to sanction an application to the Board of Trade for the appointment of an arbitrator. This recommendation was approved.

PORTISHEAD: *Provisional Order.*—The Western Electrical Co. have notified the Council of their intention to apply to the Board of Trade for a Provisional Order authorising the supply of electricity within the urban district. It may be pointed out that the company obtained an order a few years ago, but it was revoked by the Board of Trade.

REDDITCH: *Electricity Accounts.*—At the last meeting of the Urban District Council the Chairman of the Electricity Committee reported that the balance-sheet of the electricity undertaking, in common with all other electric supply undertakings, had been severely affected by the high price of coal, coupled with serious trade depression. At the same time, although the balance-sheet was unfavourable, they had just received an order for the supply of energy for power purposes which placed the undertaking practically in the same position as it was before they lost a considerable amount of trade through several firms leaving the town.

RODLEY: *Electricity Supply.*—The Leeds Corporation Electricity Department have under consideration the supply of electricity in this district.

ROSSENDALE: *Electric Supply.*—An important conference has just been held at Rawtenstall of representatives of the boroughs of Bacup, Haslingden, and Rawtenstall, called by Mr. Hooper, of the Local Government Board, to secure, if possible, arrangements whereby three boroughs might be most suitably and economically supplied with electric current, instead of having three separate schemes. Rawtenstall agreed to accept the offer of Bacup to forego its right of supplying its own tramways with electricity, and allow Rawtenstall to supply them; and that in consideration of this, should Bacup want current for lighting purposes, the fact of their taking electricity for the tramways should be taken into account in fixing the price. The Inspector was unable to bring about an understanding between Haslingden and Rawtenstall, a Haslingden representative stating, at the close of an acrimonious discussion, that so far as Haslingden is concerned, they were not prepared to go any further in the matter.

SOUTHALL-NORWOOD: *Electric Supply.*—The Urban District Council has decided to inform the Metropolitan Electric Lighting Company, that the Council cannot accept their proposals for public lighting, but is willing to consider any offer the company may make to purchase the Order and powers of the Council without conditions.

SUNBURY: *Electric Lighting Provisional Order.*—The Urban District Council has received notice of the Electric Light & Traction Co.'s intention to apply for a Provisional Order to supply current in the Council's district.

TASMANIA. *Launceston: Electric Tramways.*—The plans for the electric tramway system have been approved by the City Council, and the work has been commenced.

TEWKESBURY: *Electric Lighting.*—The Hereford Town Council has agreed to allow its Surveyor to act as advisory engineer to the company about to be formed under the Tewkesbury Electric Lighting Order, but at the next meeting a resolution will be moved that this decision be reconsidered.

WEST BROMWICH: *Tramway Accounts.*—The Borough Treasurer's abstract of the accounts for the year ended March 31st, 1908, shows that the amount received as rent up to date from the South Staffordshire Tramway Co. was £6,979, and from the Birmingham and Midland Tramways Co. £1,627. There was a deficit on the tramways undertaking on March 31st of £1,092.

WEST HAM: *Tramway Profits.*—The Borough Treasurer, in his report upon the accounts of the Corporation tramways for the year to March 31st, states that the revenue account shows a total expenditure of £76,717, and income of £120,013. After providing for capital charges the sum of £5,378 is carried to the relief of rates.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

DARTFORD.—A Local Government Board inquiry has been held into the application of the Urban District Council for sanction to borrow £2,880 for an extension of condensing plant at the electricity station for an additional feeder cable and for house-service cable, which, it is estimated, will be required during the next three years.

ECCLES.—Mr. H. R. Hooper held an inquiry at Eccles on July 28th into the Council's application to borrow £16,278 for the purposes of electrical extensions.

EDMONTON.—The Guardians invite tenders for an electric-lighting plant at the Nurses' Home, Upper Edmonton. Particulars from Messrs. May & Hawes, Caxton House, Westminster (fee £1, returnable), and tenders to the Clerk, White Hart Lane, Lower Tottenham, by August 26th.

GILLINGHAM.—Mr. H. R. Hooper held a Local Government Board inquiry last week into an application for sanction for further capital in connection with the electricity undertaking. The proceedings were private.

LEYTON.—At the last meeting of the Urban District Council sanction was received from the Local Government Board to the borrowing of £895 for providing additional plant at the generating station.

MANCHESTER.—The Electricity Committee invite tenders for the supply, delivery, and erection of (1) storage battery at the Stuart Street station, and (2) low-pressure pipe-work, including exhaust steam air-pump discharge and circulating water-pipes and two atmospheric exhaust valves at Dickinson Street station. Specifications from Mr. F. E. Hughes, Secretary to the Electricity Department (fee, £2 2s. for each specification), and further particulars from the City Electrical Engineer, Mr. S. L. Pearce. Tenders to the Chairman of the Electricity Committee by August 12th.

METROPOLITAN ASYLUMS BOARD.—Tenders are invited for the installation of a storage battery, motor-driven booster, switchboard, and connections at the training ship *Exmouth*, Grays, Essex. Particulars from the offices of the Board (fee £2, returnable), and tenders to the Clerk by September 1st.

SURBITON.—At the last meeting of the District Council, the Parliamentary Committee reported that there was every reason to expect at an early date the Local Government Board's sanction to the proposed loan for electric light extensions. The Committee recommended that immediately on receipt of the sanction tenders should be invited and submitted to a special Council meeting. The matter was referred back to the Committee for further consideration.

WATFORD.—Tenders are invited for a surface condenser complete with steam-driven pumps. Particulars from the Electrical Engineer (fee £1, returnable), and tenders to the Town Clerk by September 1st.

Miscellaneous

CHILE.—*Commercial Intelligence* states that the management of the State Railways of Chile has advertised for bids for the construction of an electric plant at San Eugenio, comprising the building and the machinery for the production of motor force in the shops and the lighting of the stations, with a capacity of 900 kilowatts, divided into three units of 300 each. No proposals will be considered that are not made upon the form that will be found in duplicate on the leaf of specifications furnished free of charge by the engineer of the technical office, upon a deposit of 60 pesos with the central cashier of the service. The work must be executed in conformity with these specifications. At the time of receiving the specifications the interested party or his representatives will sign the volume kept for this purposes in the central office, giving their name and the domicile of the house they represent. The management reserves the right to reject all proposals, to accept any part of any of them, or to accept the one most convenient, even though it is not the lowest. The proposals will be opened in the presence of the interested parties on Monday, November 2nd, 1908, at 3 p.m., in the office of the Director-General of the State Railways, Santiago, Chile.

DONCASTER.—The Rural District Council have instructed Messrs. D. Balfour & Son, of Newcastle-on-Tyne and London, to prepare plans for an additional pumping station for the sewerage of Bentley-with-Arksey and Rostholme. The work includes the laying of the necessary sewers and the construction of a storage tank, engine-house, including electric motors and pumps.

INDIA.—It is stated that a detailed scheme for the conversion of the Nilgiri Railway to electric traction, and for the lighting of Ootacamund, Coonoor, and Wellington is recommended.

NEW ZEALAND.—The Board of Trade correspondent at Auckland (Mr. A. J. Denniston) writes that, according to the local Press, the Auckland Harbour Board are calling for tenders for the supply of 16 electric cranes. Tenders by October 1st to Messrs. W. & A. McArthur, Ltd., of 18-19 Silk Street, London, E.C., at whose offices copies of the specifications and diagrams may be seen.

NORWICH.—Tenders are invited for a sewage screening and electrical lifting gear for the Corporation. Full particulars from the City Engineer, Mr. A. E. Collins, Guild Hall, Norwich, and tenders to the Chairman of the Sewage Committee by September 21st.

RAWTENSTALL.—Tenders are invited for the supply and delivery of sixteen tramcars; also for station lighting, wiring, and motor-testing instruments, &c. Full particulars from Messrs. Lacey, Sillar & Leigh, 2 Queen Anne's Gate, Westminster, and 78 King Street, Manchester, and tenders to the Town Clerk by August 15th.

Digitized by Google

SOUTH AFRICA.—The conversion to electric traction of the railway line between Cape Town and Wynberg is contemplated.

Parliamentary sanction is being sought for an electric tramway service in Boksburg.

TWICKENHAM.—Tenders are to be invited for electric fittings for the Infectious Diseases Hospital.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

E.—New warehouse and alterations to warehouse (£1,900) in Aldgate for L. & N.W. Railway Co. Architects, Joseph & Smithem, 85 Queen Street, E.C.

E.C.—Buildings in Clerkenwell for Sir W. P. Hartley, Green Walk, Tower Bridge Road, E.C.

Alterations, Training College, Moorfields (£1,067). Builders, J. Grover & Son, New North Road, N.

Additions to Training College, Graystoke Place (£608). Builders, E. Laurance & Son, Wharf Road, City Road, E.C.

Alterations, &c., business premises, Fort Street (£880). Architects, Gordon, Wilson & Co., 667 Fulham Road, S.W.

N.—Schools, Islington (£8,675). Builders, W. Johnson & Co., Wandsworth Common, S.W.

N.W.—School in St. Pancras (120 places). Architect, T. J. Bailey, Education Department, L.C.C.

New offices for Zoological Society. P. C. Mitchell, Secretary, 3 Hanover Square, W.

S.E.—Alterations, Dulwich Fire Station (£885). Builders, G. & C. Bowyer, Upper Norwood.

Additions to school, Sydenham (£400). Architect, T. J. Bailey, Education Department, L.C.C.

Alteration of premises, Woolwich (£450). Builders, Johnson & Co., Wandsworth Common, S.W.

S.W.—Alterations, Chelsea Fire Station (£613). Builders, J. & C. Bowyer, Upper Norwood.

Alterations, school, Bermondsey (£9,466). Builders, W. Johnson & Co., Wandsworth Common, S.W.

Additions to Battersea Polytechnic (£5,183). Joseph Harwood, Secretary, Battersea Park Road, S.W.

New fire station, Waterloo Road (£11,000). Builder, H. L. Holloway, Church Street, Deptford, S.E.

Additions to school, Battersea (£10,688). Builders, W. Johnson & Co., Wandsworth Common, S.W.

W.—School in Hammersmith (80 places). Architect, T. J. Bailey, Education Department, L.C.C.

Additions and alterations, Paddington Workhouse. Architect, F. J. Smith, Parliament Mansions, Victoria Street, S.W.

Additions to Paddington Technical Institute (£10,700). Architect, T. J. Bailey, Education Department, L.C.C.

Alterations, 131 Regent Street. Parkinson and Son, Fisher Street, Southampton Row, W.C.

W.C.—Adapting 13 Southampton Row for occupation by Pope & Bradley, tailors, 87 Theobalds Road, W.C.

Alterations and repairs to premises *Illustrated London News*, Milford Lane, after fire.

PROVINCES.

BATTLE.—Partial rebuilding (after fire) of Lord Brassey's mansion.

BECKENHAM.—Four shops and houses. Architect, J. Farrer, 2 Coleman Street, E.C.

BRIGHTON.—Additions, London Road Congregational Church (£1,000). Architect, E. J. Hamilton, 2 New Road, Brighton.

BRISTOL.—Extensions of business premises in Castle Street. Architects, La Trobe & Weston, 44 Corn Street, Bristol.

BROMLEY.—Re-erection of Mason's Hill School. S. E. Osborne, secretary to managers, 1 Exmouth Road, Bromley.

BURSLEM.—Additions to Wedgwood Institute (£5,000). F. Bettany, surveyor, Town Council.

CARSHALTON.—Houses. Builder, A. B. Cook, Wallington, Surrey.

Alterations to Southern Hospital. Engineer, W. T. Hatch, Metropolitan Asylums Board, Embankment, E.C.

CHELTENHAM.—New municipal offices (£10,000). Borough Surveyor, J. S. Pickering.

CROYDON.—Seventeen houses. Architect, D. L. Gooch, 54 Gresham Street, E.C.

Eighteen houses. Architect, Stanley Peach, 28 Victoria Street, S.W.

Ten houses and shops. Architects, Pepler and Allen, 3 George Street, Croydon.

HANWELL.—Additions to asylum (£2,000). W. E. Riley, superintending architect, L.C.C.

HOUNSLOW.—Infants' school and house (£4,000). Builder, W. Lacey, Staines Road, Hounslow.

KETTERING.—Additions and alterations (£3,500), Police Station. C. S. Morris, County Surveyor, Northampton.

KINGSTON (Surrey).—Workmen's Club. Builder, F. Hawkey, 81 Brighton Road, Surbiton.

NEWPORT.—Additions to schools (£3,500). Architect, C. F. Ward, c/o Education Committee.

NOTTINGHAM.—Memorial Hall (£1,500). Builders, W. Maule & Co., 190 Mansfield Road, Nottingham.

ROWLEY REGIS (Staffs.).—Public libraries (£5,000). Architects, Wills & Anderson, 4 and 5 Adam Street, Adelphi, W.C.

SALFORD.—Alterations County Courts. H.M. Office of Works, Storey's Gate, S.W.

SUTTON.—Reconstruction of Belmont Asylum. Clerk, Fulham Guardians, 120 Fulham Palace Road, S.W.

WOODFORD (Essex).—Additions to asylum. W. E. Riley, superintending architect, L.C.C.

UXBRIDGE.—Partial rebuilding of Yeading Hospital. C. Woodbridge, Clerk, Joint Hospital Board.

Alterations to Council Chamber. Architect, W. L. Eves, 54 High Street, Uxbridge.

WALTHAMSTOW.—Central library (£8,773). Architect, J. Williams Dunford, 109c Queen Victoria Street, E.C.; builders, Brand, Pettit & Co., South Tottenham.

WINDSOR.—New block of barracks. Director of Barrack Construction, 80 Pall Mall, S.W.

TENDERS RECEIVED AND ACCEPTED

AUSTRALIA.—The New South Wales Postmaster-General's department has accepted the tender of the British Insulated & Helsby Cables, Ltd., for 14¼ tons of hard drawn copper wire (300 lb. to the mile) at £70 18s. per ton, and 4 cwt. of copper binding tape (200 lb. to the mile) at £4 2s. per cwt. The tender of Messrs. Siemens Bros. Dynamo Works, Ltd., for 3,500 best white porcelain insulators at 6½d. each has also been accepted.

The Victorian Postmaster-General's Department has accepted the tender of Mr. R. P. Hunderford, of Sydney, for 11 sections of a common battery switchboard, and 3,000 subscribers' telephone and other apparatus at £19,303.

BIRMINGHAM.—The Tramways Committee have accepted the tender of Mr. E. Crowder for the erection of a tramway depôt in Miller Street at £7,877.

The tender of the General Electric Co., Ltd., has been accepted for an induced draught plant at £350.

CANADA (ONTARIO).—Twenty-seven tenders have been received, many from the United States and Europe, for the construction of the transmission line from Niagara to Toronto. The Special Commission which has the matter in hand is now considering these tenders.

CHIPPING NORTON.—The D.P. Battery Company, Ltd., have secured the contract for the supply of a battery of their L 15 type cells for the above central station.

COTTESLOE (WEST AUSTRALIA).—The D.P. Battery Company, Ltd., have received an order for the renewal with their W.L. 9-type, of the above battery.

CROYDON.—The Corporation has accepted the tender of Babcock & Wilcox, Ltd., at £530, for mechanical stokers; also the tender of Casperd & Co. at £151 for installing electric light in the Scarbrook Road swimming bath.

HASLINGDON.—The Board of Guardians has accepted the offer of the Corporation for a supply of electrical energy at 3d. per unit.

HULL.—With regard to the supply of new transformers for factory sub-stations, Mr. H. Bell, the Electrical Engineer, has reported that as the department already has thirty-four such machines made by Messrs. Thomas Parker, Ltd., of Wolverhampton, which were of special design and were working quite satisfactorily, it would be wise for the Committee to order similar machines in the present instances. Messrs. Thomas Parker had signified their willingness to supply the additional transformers and switchgear at the same rates as under a previous contract, and this recommendation was adopted.

ILFORD.—The Urban District Council has accepted the following tenders:—Cole, Marchent & Morley, Ltd., surface condensing plant and cooling tower, £1,954; John Spencer, Ltd., steam and feed pipes, boiler feed pump, &c., £529; The Walsall Electrical Co., Ltd., extensions and alterations to main switchboard, £418.

LONDON: *Stepney.*—The tender of the Fulham Steel Works Co. for the framework of the Blythe Wharf generating station has been accepted at £15,609.

Fulham.—The Electricity and Lighting Committee of the Borough Council has accepted the following quotations for a crane and grab and electric motor to be provided for clearing the river sump at the electricity works, at a total estimated cost of £178 (which amount includes £20 for foundations, fixing

Digitized by Google

machinery, &c.) :—Lewis & Lewis, crane, £64; Priestman, grab, £59: The British Thomson-Houston Co., electric motor, £55.

Hammersmith.—The Council have renewed the contract of the Main Colliery Co. for the supply of Graigola and Victoria coal at 15s. 1d. per ton for twelve months, and have accepted the quotation of Cory Brothers & Co. of free burning coal from Pentre Colliery, Rhondda Valley, at 14s. 11½d. per ton for twelve months. For static transformers the following tenders have been received :—100 kw., British Electric Transformer Co. (accepted), £112; Johnson & Phillips, £101 5s.; Siemens Bros., £106: Brush Electrical Engineering Co., £127; 200 kw.: British Electric Transformer Co. (accepted), £175; Johnson & Phillips, £148; Siemens Bros., £140; Brush Electrical Engineering Co., £203. Only the British Electric Transformer Co., Ltd., was able to quote in accordance with Council's present machines, viz., air-cooled transformers. He could see no advantage in departing from the present practice.

Hampstead.—The Board of Guardians has accepted the tender of E. R. Smith, Hampstead, at £18 5s., for making the necessary alteration for reducing the voltage of electric current at the workhouse from 210 to 105, it having been decided that in future metallic filament lamps be used.

Islington.—The Council received eleven tenders for the erection of a cooling tower, and accepted that of the Midland Engineering Co., Ltd., Birmingham, at £2,170.

Marylebone.—The Borough Council received the following tenders for electric light fittings at premises in Somerset Street :—Donnison, Sillem & Co. (accepted), £26; W. Mossop & Co., £28; Roger Dawson & Co., £35; Rashleigh, Phipps & Co., £41.

The following tenders have been received for the supply of half-a-mile of 0·15 sq. in. T.C.C. paper-insulated, lead-covered, jute served and compound cable :—W. T. Henley's Telegraph Works Co., Ltd. (accepted), £287 10s.; British Insulated & Helsby Cables, Ltd., £287 10s.; Siemens Bros., Ltd., £287 10s.; W. T. Glover & Co., Ltd., £287 10s.; St. Helen's Cable Co., Ltd., £295; Callender's Cable & Construction Co., Ltd., £295.

The tender of Siemens Bros. & Co., Ltd., was accepted at £69 10s. for the supply of four circuit-breakers. Five firms sent in tenders, and that accepted was the lowest.

St. Pancras.—The Council at their last meeting accepted the following tenders for the supply of coal to the electricity department: J. H. Beattie & Co., 11,000 tons Bolsover (Mansfield) best nutty slack coal, at 12s. 4d. per ton (King's Road generating station); Brentnall & Cleland, 10,000 tons Desford steam coal (Regent's Park Station) at 14s. 8d. per ton, and 1,000 tons at the same price to King's Road; Facer & Co., Ltd., 600 tons Bwllfa coal at £1 1s. 6d. per ton (Regent's Park Station). The Electricity Committee recommended the recission of the bye-law with regard to trades union rates of labour, in order to accept a tender by Messrs. Beattie at 11s. 6d. per ton instead of 12s. 4d., the company having agreed to pay a minimum wage of 30s. per week to carters. The recommendation was not agreed to.

For additions to the low-tension switchboard at King's Road generating station the following tenders were received: Johnson & Phillips, Ltd. (accepted), £112; Spagnolette, Ltd., £113; Whipp & Bourne, £116; Electric & Ordinance Co., Ltd., £119; Bertram Thomas, £126; Walsall Electric Co., £126; British Thomson-Houston Co., Ltd., £131; British Westinghouse Co., £135; Cowans, Ltd., £151; Switchgear Co., £156 10s.; Edison & Swan United Electric Lighting Co., Ltd., £162; Siemens Bros. & Co., £176; E.M.F. Manufacturing Co., Ltd., £205; A. W. Penrose & Co., Ltd., £224; Electric Construction Co., £225.

LOWESTOFT.—The tender of Messrs. Mann, Egerton, & Co., for the electric wiring and fitting of the Central Boys' and Central Girls' School and the St. Andrew's Schools has been accepted.

TOTTENHAM.—Messrs. Venner & Co. have received an order for 120 "C" type time switches for the street lighting of Tottenham from the North Metropolitan Electric Power Supply Co.

WEST HAM.—The Electric Lighting and Tramways Committee has decided to accept the tender of Ferranti, Ltd., at £247 13s., for the supply of switchgear for a turbo. The tender was the lowest received.

COMPANIES' MEETINGS AND REPORTS

ANGLO-AMERICAN TELEGRAPH CO.—At the annual meeting on Friday the report and accounts given in our last issue were adopted. With regard to the net reduction in the receipts of £6,650, the chairman, Mr. Francis Bevan, said the directors did not in any way regard this as due to the effect of wireless telegraphy. The Wireless Telegraph Co. may have taken a little business from them at Montreal, but it was so little that he did not think it really had much effect upon the company's receipts. The real reason, in the directors' opinion, was set out in the report. During the last two years the company had had no trouble from trawlers on the west coast of Ireland, which was probably due to the fact that their cables at the shore end were now so strong that trawlers could not inflict the injury upon them which they used to.

BAKER STREET & WATERLOO RAILWAY CO.—The report for the half-year ending June 30th, 1908, states that the capital expenditure during the half-year amounted to £784. The gross receipts amounted to £85,528, being an increase of £20,077, or 31·64 per cent., on the receipts for the corresponding half of 1907. The working expenses amounted to £45,452, an increase of £3,324, or 7·89 per cent. After providing for interest and rents, and for dividend at the rate of 4 per cent. per annum on the preference shares, and crediting to net revenue account £2,142 5s. 8d. receivable from the Underground Electric Railways Co. of London, Ltd., under their guarantee agreement, there remains a balance of £9,854 10s. 6d. available for dividend on the ordinary shares, and the directors recommend that a dividend at the rate of ¾ per cent. per annum be declared on the ordinary shares, and an additional dividend at the rate of 2¼ per cent. per annum (making 3 per cent. per annum in all) on the ordinary shares other than those held by the Underground Co. or their nominees. The number of passengers carried was 12,940,801, being an increase of 3,003,806 over those carried during the corresponding period of 1907. The meeting is on the 11th inst.

BRITISH THOMSON-HOUSTON CO.—At the annual meeting last week the report and accounts given in our last issue were adopted. Mr. H. Nauheim, who presided, said the company's position was distinctly better than last year, although business at the present moment was not particularly brisk. They had been able to further reduce their indebtedness by a considerable sum, and had begun the redemption of their debentures.

CENTRAL LONDON RAILWAY CO.—The report for the half-year ending June 30th, 1908, shows that the capital expended during the half-year was £52,288. The chief items are for the additional generating plant at the power house, and the extension of the line from Shepherd's Bush to Wood Lane. Compared with the corresponding period in 1907 there has been an increase of £8,761 in the revenue receipts, and of £185 in the working expenses. The balance carried to net revenue is £83,526. After providing for interest on the debenture stock and other payments, there remains a balance of £74,125. The directors recommend the declaration of the following dividends :—On the undivided ordinary stock at the rate of 3 per cent. per annum for the half-year; on the preferred ordinary stock at the rate of 4 per cent. per annum for the half year. Dividend on the deferred ordinary stock not being payable until the result of the year's business is ascertained, the balance remaining of £54,671 is carried forward to next half-year. The number of passengers carried was 19,901,750, compared with 20,260,871 in the corresponding half-year of 1907. The Franco-British Exhibition at Shepherd's Bush was officially opened on May 14th last, and on that day the company's trains were worked over the new line sanctioned by Parliament last year, utilising also the new station at Wood Lane opposite the entrance to the Exhibition. This extension of the system adds half-a-mile to the length of railway worked. A very substantial increase in the company's business has resulted, and as tram-cars and omnibuses now run between Hammersmith and Willesden, passing the entrance to the new station, there is every prospect that an increasing traffic will be permanently carried to and from this new centre. The system of through booking between stations on the Central London Railway and those on the Baker Street and Waterloo, the Charing Cross Euston and Hampstead, the Great Northern Piccadilly and Brompton, the City and South London, the Great Northern and City, and the Metropolitan Railways, established last year, has steadily developed: about 25,000 passengers per day are exchanged with the other companies, minimising and partially replacing the loss on the short-distance traffic diverted by the motor omnibuses. The average receipt per passenger for the half-year is 1·97d., as compared with 1·85d. in the half-year ending June, 1907. The cost per passenger is 1·08d., as compared with 1·06d. in the corresponding period. The meeting is to-day.

CHARING CROSS, EUSTON & HAMPSTEAD RAILWAY CO.—The report for the half-year ending June 30th, 1908, shows gross receipts of £88,885, and working expenses £56,492, and after providing for interests and rents, there remains a balance of £852 on the net revenue account to be carried to next half-year. Since the opening of the railway the following passengers have been carried: June 30th, 1907 (eight days), 421,466: December 31st, 1907, 9,881,357: June 30th, 1908, 12,152,639. The meeting is on August 11th.

CITY OF LONDON ELECTRIC LIGHTING CO.—The report for the half-year to June 30th, 1908, states that the number of consumers is 12,485, compared with 12,295 on June 30th, 1907,
